NEVER SAY DIE

...de W2NSD/1

EDITORIAL BY WAYNE GREEN

Are your club meetings so much fun that at least 75% and often 90% of the club members come to each meeting . . . and you have a tough job getting them to go home after the meeting?

Okay, so a lot of clubs need ideas to get things moving. Before I throw some out on the table for you, I want to make sure that I get feedback. If you have any ideas going for your club that I don't mention, please do all of us a favor and send in a letter telling us about it. If some of my ideas perk things up, let us all know about that, too.

One of the functions of a ham club these days is to help recruit more hams. This means that all members of the club are delegated to do all they can to interest newcomers . . . getting out to CB meetings, giving talks at high schools, seeing that there are posters on the school and electronic firm bulletin boards in the area – and don't forget a poster in every Radio Shack, Lafayette, computer store, or place where CB or ham gear is sold, or where radio parts might be bought.

This process doesn't stop with the sparking of interest. Make sure your club is set to interest these people . . . classes for Novice . . . and then for Technician . . . and General. You might get things started around 7:00 with 20 minutes of code practice, though home practice with code cassettes will be a lot more productive . . . at least 15 minutes per day. Then you want to have a technical talk on fundamentals . . . another 20 minutes should be fine. Don't let these things drag. Start right on time, exactly, and members will be there on time.

Around 7:40 you can have a short business meeting. Have this as well orchestrated as possible . . . reports done quickly by each committee and officer. If there is going to be any argument on any subject, table it until after the meeting and let those interested enough in the subject to stay late and discuss it do that.

By 8:00 you should be ready for the main meeting and brief reports on special interest ham things . . . like what's been doing with DX, SSTV, nets, traffic, ATV, repeaters, the club training classes, etc. It wouldn't hurt to have a report on the content of the ham magazines, with one member reporting on each publication. I am always astounded to find some clubs where only a small percentage of the members are even aware of the material we have been publishing in *73* . . . I know there is little communication within that club. An amateur not getting *73* is losing a lot . . . the inspiration of the building articles . . . the knowledge of the state of art . . . the fuller picture on what is really happening with the FCC, the ARRL, the ITU, and so forth. And what a shame to miss out on an enormous library of articles on every ham subject. You never know when you are going to get fired up on RTTY, say, and desperately need to get caught up on it . . . so where are your back issues?

Keep the reports fast-paced and try to get to the main speaker by 8:30 (let him know your schedule so he won't have to sit through the business meeting if he is a visitor). Who can you get? Well, the club members with special interests are your first line . . . an SSTV demo and discussion . . . RTTY, microcomputers, DX talk . . . you know who your special people are. Going outside the club, you can tap ham manufacturers . . . they will go a long way to bring their latest product and talk about it.

How about DXpeditioners? They have interesting movies or slides and will get your club fired up for its own DXpedition (which isn't all that impossible, by the way). A local ham dealer will be glad to tell you of the problems and joys (which are few) of his business . . . and answer questions. Don't forget the contest fanatics, or the certificate hunters.

By 9:30 you should be ready for doughnuts and coffee or cider for about 15 minutes, then back to another short meeting to discuss club projects such as Field Day, emergency net plans, contest plans, special events. After that you can get to the tabled discussions until members start getting ready to go home. It is most helpful to try to put as much of the business which might drag on into a committee and keep away from whole club discussions. Oddly enough, members get all involved with very small matters (what color to paint the clubhouse) and argue for hours . . . seemingly enjoying themselves. But then they don't show up at any more meetings.

It's nice to leave a little time for members to lie to each other and (in general) talk at the end of the meeting. Those in a rush can get home – others can talk. Kick the last of them out by 11:00 . . . if they want to talk more they can go to a local pizza joint or something. This makes a nice windup for the evening.

Some clubs organize a dinner before the meeting at a nearby restaurant in the reasonable category. This is fun for those who enjoy having more of an opportunity to talk. If you get this going by 6:00, most fellows will be able to either make a short stop at home on the way or else go right from work.

Oh, and don't forget to have any members who get a new piece of ham gear bring it in and tell about it.

HOW TO TREAT SPEAKERS

If a speaker is coming in from any distance or is a special person of some sort, it wouldn't hurt to ask him out to dinner with a few members of the club before the meeting. This will give him a chance to get to know a little more about any special interests of the club – ask questions – and give enough information for a decent introduction.

Speakers should, in most cases, have their expenses of coming to the meeting reimbursed – particularly if it is a big deal for them. If you are flying them in, you'll meet them at the airport and red carpet things.

Many manufacturers will go to amazing lengths to help you out if you only contact them. I know that Ed Clegg has driven or flown hundreds of miles to talk with clubs, and many other ham manufacturers will do the same.

GETTING PUBLICITY

If you go to all the trouble to get in a really special speaker, you don't want a meeting with a couple dozen dozing members – you want to fill your room. Just passing the word over the repeater won't do it. Your club should have someone in charge of publicity . . . preferably someone who knows how to make posters, either with magic markers or via silk screen. Be sure that you have posters well ahead of time on every possible bulletin board . . . and club members should be able to tackle this. Supermarket bulletin boards, high schools, colleges, every Radio Shack within driving distance, Lafayette stores, CB watering holes, parts stores, ham stores, shopping malls . . . etc.

Posters are only the first step. News releases to the local papers and broadcasting media can help, too. Next you want to be sure the info is in the club newsletter . . . on the repeater a lot . . . on any low band nets . . . then try

LETTERS

REFUNDED IN FULL

Re Trigger Electronics: 8 years ago I was the proud owner of a Novice ticket and wanted to assemble a commercially-made CW xmtr for my shack. Trigger had the kit I wanted for sale and I innocently sent off the money. What arrived, however, was *not* the kit advertised, but the same rig, fully assembled, and *used.*

I was extremely disappointed and fired off a letter to Trigger. After several additional letters and having received no satisfaction from Trigger, I told them in a final letter that it was either my money back or I would send their ad (in *QST*) from which I ordered the kit, together with their sales slip and a letter of explanation to the ARRL, requesting that the League arbitrate the matter.

This prompted Trigger to refund my money in full.

I no longer subscribe to *QST* and don't know if Trigger still places ads in that monthly, but the moral seems to be: If Trigger is playing a number on you, hit 'em where they advertise!

D. Nevin WA1KLB
Northfield VT

73 is forwarding all Trigger complaints to the Illinois Attorney General for action. – Wayne.

IL VS TRIGGER

This office has on file material relating to complaints made concerning Trigger Electronics. This letter is to inform you of the status of our case against Trigger.

An amended complaint was filed against Trigger on October 8, 1976. In addition to an injunction against further advertising by and against continuing in business, we are seeking the appointment of a receiver to marshall such assets as the owner, Mr. Irael Treger, may still have, which would then be paid out *pro rata* to all persons who have complaints on file with this office.

It will be some time before the case will go to trial and, of course, we can promise no favorable results. Please be patient, however, since we hope for progress in this case soon.

Finally, I would appreciate it very much if those of you who have filed complaints would do the following:

1. If you have moved since your complaint was filed, please inform me of your new address.

2. If Mr. Treger has made refunds to you or shipped merchandise ordered by you, please inform me so we can present up-to-date files to the court when the time comes.

Thank you very much for your cooperation.

BAIT AND SWITCH

Yesterday I called Moory Electronics Company in DeWitt, Arkansas, in response to an ad on page 174 of the October *QST*. They had a number of specials listed, including one for a "demo Ham-2 rotor – $99." When I asked about it, the young lady who answered the phone informed me that it had been sold long ago and probably had left their place of business even before their first ad came out about it. However, they could supply a new unit for only $129.95 if I would place an order. The young lady I talked with further admitted that the ad was intentionally left in because it attracted lots of attention and got them in touch with many hams who might otherwise call a competitor. I did not buy anything from this company. This type of advertising is illegal in Colorado and is known as bait and switch. It consists of advertising some product at a low price and then when a prospective buyer shows up, the salesman informs him that the store either had only one of a kind in stock and that one was sold or that the advertised item is inferior in some way and should not be considered; HOWEVER, for only a few dollars more we have . . .

This incident and stories of problems that other hams have in regard to Trigger Electronics lead me to believe that we need protection from the mail order business. By we, I mean not only the prospective buyer, but the legitimate dealers who are trying their best to make a living and give fair and honest deals, too. Some possible solutions come to mind.

1. All amateur radio magazines should refuse commercial concerns advertising space in the classified sections of their magazines.

2. All commercial concerns advertising in a magazine should have to file an affidavit that they do indeed have a reasonable number of the advertised special in stock to meet reasonable demands. One of a kind specials should be discouraged, especially if they are likely to be sold out before the magazine reaches its readers.

3. We have groups of hams working as official observers, intruder watch, etc. Perhaps one more group could be formed for consumer protection. They could arbitrate legitimate differences between buyers and vendors and report unfair practices to each publication. Then each editor would have the option of stopping the unfair advertising practice.

There are probably other solutions and ways to handle this unfortunate situation and I would like to see them discussed. I would hope that there would be input from both prospective buyers and the merchants who make their living through pages of amateur radio publications.

Craig CO

NT7HEL

How do you have fun and gain rare status at the same time? Get a Special Events License! For our Helldorado Days Celebration of 15-16-17 October, I was issued NT7HEL. In 33 hours of operation, two friends – Dale AD7RDG and Don AD7NEQ – and I made exactly 1001 contacts. It was almost a continuous pile-up! I made the mistake (?) of turning the beam west to pick up a KH6 on 15 meters and half the hams in Japan jumped us. We worked 90 in one hour and 5 minutes of the heaviest pile-up I've ever seen. We had to break them down into individual prefixes: JA1, JD1, JG1, JH1, JI1, JJ1, etc.

Now the fun is over and the cards have started to come in. And I'm learning. When I gave out QSL information I requested an SASE since this is all coming out of my pocket and I could see a thousand 13¢ stamps coming out of the budget. Out of 192 cards received so far, 25 failed to provide an SASE. Those go to the bottom of the pile.

An even bigger surprise has to do with the time a contact was made. I thought that Universal time was universally used. NOT SO! 7 cards didn't show any time. To the bottom of the pile with them. 42 cards either used local time or used Universal incorrectly. There must be more time zones in the USA than I thought, because some of the abbreviations haven't been figured out yet. What's PMEDT? Some contacts for the evening hours show the correct time but the previous day – failure to advance the day when 2400 UTC passes. You ought to put together a short article on the use of UTC and urge everyone who works over time zone lines to use it. I'd do it myself but I'll be on the road for the next four weeks.

It really was a ball and I'm looking forward to the next one. If you could use an article on the operation of a Special Events station, let me know and I'll knock it out when I get settled down again.

Rod Hallen AA7NEV
Tombstone AZ

P.S. I'm a stamp collector, so envelopes with commemorative stamps are always processed first. Some QSL cards are very hard to decipher. The cards that have the boxes to fill in on the front are the easiest to read. Some of the cards with the report on the back don't leave much room to write, which makes it hard for the recipient to read. Also annoying is having the call on one side and the report on the other. Little things, but they add up when you have a lot of cards to process. I'm much more in sympathy with QSL managers and DX stations. I'm going to redesign my own card and get some printed soon.

MORE YASME

This is a report on the successful YASME DXpedition by Lloyd and Iris Colvin operating on St. Thomas, US Virgin Islands as W6KG/AJ3.

Including operation in the phone portion of the CQ-WW-DX Contest, some 6,800 QSOs were made. Operation was from 8 October through 31 October 1976. QSOs were made with radio amateurs in 125 different countries. Conditions were better than normal and it appears that the sunspot cycle must indeed be on the upswing. For example, WAC was made on 7 MHz on 18 October in 3 hours and 50 minutes. Stations worked were 4X4GD, VK1RM, G3ZDW, W2PN, PY1NEW and CN8AD. On 27 October, WAC was made on 14 MHz in 60 minutes. Stations worked were ZS1XR, OE1UZ, VK2QL, UI8IZ, W1BFT and PY1EUM.

THE OPPOSITION

In one of your recent columns, you asked for some input from your readers on the constant argument of ICs, computers, etc., vs the more traditional ham equipment and activities. I think enough of your magazine and your viewpoint to tender my reply.

I must side with the opposition. I'm still struggling along with my WN callsign, and 15 wpm seems to be an impossible dream. To read articles on keyers capable of 60 wpm, rotator brakes, etc., just turns me off. And though your magazine is by far the best I've seen regarding articles for amateurs who are either Novices or new Generals, I don't like the trend I see toward more and more of the esoteric.

Maybe I am expecting too much, but what I need is help in the basics: How do I put out a readable signal when I am a renter (no beam antennas on the roof, no 250 foot long antenna wires out of the window), using the only equipment available to me (a transmitter no one else has ever even heard of, a Globe DSB-100, and an Allied receiver that more or less works, sometimes, I think, maybe?), and when I must compete with $2000 rigs that put out more Watts than my rig could generate in the destruct mode? And I can't help but feel that many other hams find themselves in the same fix. Those of us in this fix don't need articles on a super wide band antenna built at reasonable cost (who says $100-$200 is reasonable?), when that antenna requires 300 square feet of unobstructed land. What we need is an article on how to make do with a homemade 30' vertical that is standing in the middle of my tomato garden, the only spot open for it. Loading, swr, radiation pattern . . . ? I don't have any idea, and really don't care, because it is all I have, and it has to make do. But why won't someone tell me how to make it work better? Every antenna article I've ever read, in *73, QST, Ham Radio, Antenna Handbook*, etc., starts off on the unstated premise that the interested ham has unlimited funds and ½ of Kansas at his disposal to play with. But it just isn't so!!

Regarding the argument about ICs . . . yes, I agree they are the thing of the future. As surely as transistors pushed out tubes, ICs will soon be the *only* thing. I'm sort of sorry to see them go, but it will happen nonetheless. But granting this, that ICs are here to stay, does it follow then that every application of ICs should be of interest to hams? I refer, of course, to computers, microcomputers, microprocessors or whatever. To my mind, this entire field of computers is separate and distinct from ham radio — perhaps related and perhaps useful, but distinct nonetheless. I respect your interest in the magic boxes, but it isn't for me and I rather resent its intrusion into a ham magazine, except if it is directly applicable to ham radio.

Along this latter line, let me tell you one more peeve I have. Your magazine (and many others as well) keeps showing articles on computers that can call CQ, answer calls, log the entry, dump the contact if it's a duplicate and in general handle the entire contact except for a few blanks the operator must fill in, such as RST reports. My question is this: What is ham radio all about? Where is the dedicated amateur, twisting dials, fighting QRM, and sharing contacts with other people? If I want to have a computer do my contacting for me, I pick up my telephone. My ham gear is for fun, people-type fun, not machines. Sure, the computer is more efficient, but is it ham radio? I personally hope not. This is one of those situations where progress may be at too great a price, a price paid in the loss of personal contact, personal exchange, and loss of a great heritage of people dealing with people.

I'm sorry I rambled on, Wayne, but as I said at the outset, your magazine means something special to me, and I felt it worth the effort in writing all of this to you.

Keep on pushing for hams and ham radio. Your voice calling in the wilderness will be heard; such voices always are, eventually.

John P. Cranston, MO WN2DYU
Corning NY

P.S. Along the same lines, why is it that amateur gear is so expensive? The units are mass produced, are not especially complex, and yet are offered at prices that are virtually unreachable. An antenna made up of $10.00 worth of aluminum, a few dollars of hardware, and based on no exotic research, is marketed for 50+ dollars. Transceivers are outrageous, accessories untouchable! Who is playing whom for the sucker here? How about a voice for the ham who doesn't have a multi-hundred dollar budget for his hobby, crying for a good but simple and inexpensive unit, without all the frills and gadgets, but functionally sound (I for one am still quite happy reading dials, and can really see them as well as I can see LEDs glowing their pretty $$$)? Thanks again.

Ham gear expensive? Hmmm. There are several reasons, and perhaps this will be of interest. First, let's take a quickie back through memory lane to 35 years ago. I ran across the invoice the other day for my T-125 tube — $12.50! To put that into perspective, I was working a 45 hour week at the time and making $40 as chief engineer of a broadcast station. That 125 Watt tube cost about one third of a week's pay. The crummiest receiver available, the Hallicrafters Sky Buddy, was about $20 — half a week's pay . . . and it was pretty poor. How much does the chief engineer of a 1000 Watt broadcast station get today? Probably over $300 a week, so you compare value of ham gear then with now. Okay, now as to how the figures mount up. First comes the matter of the cost of designing and prototyping the circuit — then the mechanical parts which have to be made specially — have you priced cabinets recently? The manufacturer has to count in the cost of parts, of following up on the parts orders and trying to get delivery, of storage space and inventory control of parts, of testing and returning bum parts, of phone calls and letters trying to get replacements for bum parts, of salaries for the people to do all of this, of getting PC boards made, of checking them on delivery, of assembling the equipment, testing it, having the package designed and made specially for the equipment, packing it, writing the instruction books, having them published, writing the advertising, the cost of ads (which is not insignificant), answering letters from customers, writing and publishing specification sheets and booklets, overhead of the building, heating, telephone, payroll taxes, management costs, banking costs, Master Charge commissions, 25-40% extra for the dealers, 10% for the manufacturer's representative, maybe a little profit for the manufacturer, shipping costs of everything involved, costs of repairs and the records and bookkeeping involved, support of an accounting firm and their dependents, support of at least one lawyer and his firm, his telephone, etc. It mounts up. Did I mention the costs of attending conventions? Only mighty rough competition keeps the costs of ham gear from going out of sight — the fact is it takes a very tight-fisted firm to compete and no one that I know of is getting rich. — Wayne.

MORE OPPOSITION

In one issue — or two — of *73*, you asked for opinions on the I/O portion of *73*.

I have approximately every copy of *73, CQ* and *QST* for the past 23 years. I have dropped *CQ* as of 2 years ago; I will drop *73* whenever the subscription expires. I like the radio portion — always have — but the I/O section I consider a poor "filler." It takes the place of ads of amateur radio gear — and articles.

I am not against learning something new as you implied to anyone beefing against this crap — but simply confine my interests in solid state to communications items. I would enjoy advertisements much more. As it is, most advertisement is for I/O parts and associated trash — very little radio! Why claim a "radio magazine" when over 60% is totally unrelated electronics? Along with the change of size and format, why not change the title to reflect what it really contains? It isn't amateur radio!

N. P. Walker W5GOS

CQ 11m?

To: Federal Communications Commission
CB and Amateur Department
Rule Change Section
Washington DC 20554

Re: Petition to Change Rules and Regulations. Proposed rule and regulation change permitting amateur use of the 11 meter CB band and other CB bands; requiring amateurs to abide by all CB rules and regulations; permitting the use of amateur station callsign, rather than the CB callsign.

Dear Sirs:

This is to request a change of rules and regulations permitting the use of the 11 meter CB band and other CB bands by amateur station licensees, subject to all CB rules and regulations. The only change would be the use of the amateur station callsign rather than a CB station call. Rules for obtaining a CB license, in this instance, would not be pertinent, since license was obtained in an amateur manner. Amateurs, when operating in the CB bands, would be considered CBers as far as International Treaty or the like. All classes, Novice through Extra, would be affected. Commercial use of the amateur callsign in this instance would not be prohibited.

Discussion *PRO* change of rules:

1. Amateurs will act as "goodwill ambassadors" possibly encouraging a certain portion of CB operators to become hams. This would be a positive effort to aid the FCC in the control of the "CB problem." Hams are on the "FCC side" and are of positive help and aid.

2. Change of Rules and Regulations would pose no problem in implementation and cause no additional government cost for administration.

3. Approximately 280,000 less CB callsigns would be necessary to be issued by the FCC — a saving in government operating cost. (There are approximately 280,000 hams.)

4. In keeping with the stated FCC policy of "deregulating hams."

5. Historically the 11 meter band was a ham band — such a return is feasible.

Discussion *CON* change of rules:

1. I can't think of any disadvantages or con — the change of rules and regulations is positive and constructive.

Please acknowledge my petition — then let me know your decision.

LOW PRIORITY

Another childhood illusion shattered — namely that if you get ripped off via the mails that Big Daddy will make it all better.

About one year ago Environmental Products went down the drain. They had an excellent newsletter that I had subscribed to. One of the surviving principals offered through the mails to keep the newsletter going. I sent money and got nothing in return. After a decent interval of waiting (some six months), I entered a formal protest with the proper postal authorities.

My notification of the ripoff went to the Postal Inspector in charge out in Denver CO. One grand hell of a time later, this gentleman finally notified me that a United States district attorney had investigated the firm and had "declined to prosecute." I was further advised that I could write to a Mr. John R. McKown in Colorado, who had indicated that he would stand good for the loss. To date nothing has been heard further on the matter.

Perhaps if you were a large company who had access to a legal staff to

press the matter of why a mail ripoff is allowed to go unprosecuted, you might stand a chance of making recovery. As a lone individual, it seems that Uncle Sam really does not care. If you do not pay your taxes, that is one thing . . . if you look for some service for your tax money, evidently that is a matter of a much lower priority.

Allan S. Joffe W3KBM
Dresher PA

THE HFers

Lots of activity on 11 meters out here — both in and out of the band. Most any evening I can find 6 or more QSOs between 27.255 and 27.500, on SSB mostly. Heard one fellow brag about his new $850 imported SSB rig on 27.400 — didn't seem to know he was illegal as all get out. Several times I have found SSB QSOs in the low end of ten meters. All I can do is tune up and call CQ on CW — seems to discourage them for several days. Is there any way to talk to them within the law? I think they would be happy to start classes somewhere if they could without any hassle or someone putting them down. I think we who communicate by radio need a "common band" where anyone can operate regardless of license class — maybe our ham tickets could be made to include some operation on 11 meters. If these people sat in on a net once or twice they would see that a ham ticket is worth its weight and a very desirable thing to have.

That's all for now. My pen still can't spell but I keep trying.

John E. Winter WB6EUK
Garden Grove CA

KUDOS—HEATH

We hear a lot about dirty deals hams get from the different dealers. No doubt they get comments which reflect the abuse felt by those who resent it the most, but we are taking for granted the good treatment received from the majority of the dealers. A case in point is as follows: On March 15, 1976, I ordered an HW-101 from Heath and did not get around to putting it together for four months. About six weeks ago I got out the kit and started to put it together, since I was unable to previously due to college work.

I found at first that the mode switch was defective as it had one of the wiper contacts missing. Having an assortment of switches, I robbed one of its contact and restored the switch, but wrote Heath about a new switch so I wouldn't have to worry about it later. In less than 10 days a new switch arrived, no charge. Then I found a bad carrier oscillator crystal which they also promptly replaced; in fact, it was removed from one of their working units (a prototype, probably) so I wouldn't have to suffer a six week delay when ordering a single unit from their supplier!

I've built the SB-102, SB-200, Heath wattmeters, scopes, tunnel dippers, transistor checkers, etc., and outside of one other bad transistor, they've been 100% good. Then to receive replacement parts after the warranty period has expired is uncommon and laudatory.

I also commend them on sticking with the amateur fraternity when other manufacturers have moved to some specialized part of communications which provides a quicker cash profit.

So when it comes time to relieve the pressure that has been building up in some little bank account somewhere, we should remember those who've stuck with us and provided good service through the years. When other manufacturers and dealers begin to realize that good service attracts good customers, perhaps the practice will spread. It should be encouraged!

Now . . . how much was the HW-104? Hmmm!

Robert B. Lunsford, Jr. WB5QGI
Killeen TX

REFLECTIONS

Thanks for your article, "Exploding The Power Myth," in December, 1976 of *73*.

For approximately a quarter of a century, off and on, I have studied and restudied reflected power. It has always bugged me, as I have never been able to grasp how power can be reflected backwards. As the articles I was studying came from such reliable sources as the ARRL and college textbooks, I felt I was lacking in mentality and ready to turn in my EE degree and Mensa pin. When *QST* carried a lengthy series of 3 articles on this subject about a year ago, you know I was upset when I was confused once again.

However, I do believe that you, through *73*, have started to set the record straight . . . there is no such thing as reflected power. I hope the ARRL corrects its publications.

William Richrath K9IEN
Elmhurst IL

APPLES 'n ORANGES

Thanks for forwarding me a copy of the *HR* article of August, 1976 by W2DU which talks of coaxial dipole antennas and mentions my *73* article of June, 1973. I don't subscribe to *HR* because it often seems to be just an outlet for frustrated theorists who can't publish in *QST*.

The need for W2DU's ungentlemanly and inaccurate footnote escapes me. He tries to sound very professional but he is comparing apples and oranges. My *73* article was mainly a practical construction article of 2½ pages (old, small page size) while he presents a rambling 14 page (new, large page size) mathematical exposé which concludes that the advantages many amateurs found in practice for the coaxial dipole configuration are not theoretically supportable. His statement that I said 50 Ohm transmission line "must" be used is incorrect. I said one should use 50 Ohm line because of constructional convenience.

He clouds a possibly better understanding of the antenna systems we use — which any open-minded amateur would welcome — with arrogant insult to other amateurs who have experimented in the antenna field. I am surprised the editor of *HR* would accept such material.

John Schultz W2EEY/K3EZ
73 Magazine Staff

AWE AND RHAPSODY

I well remember evenings and weekends spent in awe and rhapsody over many a back issue of *73*, some going back to 1960 and 1961, when they were 37¢ (two for 73¢!). The excitement was heightened all the more by the undergraduate pressure of hard study, nagging me that I should be doing something else . . .

But those days were vividly recalled as I paged through the histories, biographies, and thought-provoking fictions in your November '76 issue. Back came some of the previous stories I'd seen on the wildly imaginative but forgotten genius Tesla — aided by that wonderful high-voltage explosion of sparks in the photograph. Perhaps the best service Harry Goldman did for both Tesla and myself was the extensive bibliography attached to the article. I'm glad *73* hasn't let this man's energies go loose in history and has kept up with his founding work on ac electricity.

Then there's Ken Cole's marvelous account of his experiences in WW II. If there was an award given for the best amateur radio magazine article of the year, "Paolo" should win it. Cole's style kept up the haunting mistiness of the whole adventure, while the photos drove home the realistic tensions of the war. Human interaction, across "enemy" lines, an interest in radio as a hobby, and history all very well interwoven into a readable, believable account.

Rexford and Emelie Matlack's research on "The Quiet Spy" came through well as the story unravelled — newspaper clippings and photos from old magazines added to the realism. I think this kind of work is not a sick kind of return to the nostalgic "good old days," but rather a service to younger hams who can begin to appreciate the obvious richness and diversity of service (and fun) the hobby provides.

And along those lines, Howard Burgess' notes on pioneer efforts directly related to amateur radio seem to pull all these human interest/historical stories into the present: What can we, as experimenters, do *now* with our knowledge and inherent bent for fooling around without strict recourse to the sometimes stifling methods of science? After all, it's usually the amateur generation who break from the past and make new discoveries — if you need a source of these freer minds, look at the work being done in microprocessor control of repeaters or RTTY stations. "Who, Me? A Pioneer?" invites some serious thinking on everyone's part to say yes when all others shrink away from a problem and think you're crazy.

All this and the bodily resurrection of Hank Olson's S-38 too! The best thing to do with that beloved excuse for a receiver is to dump it into the bay or the harbor, depending if you're still in San Francisco or near Boston.

An excellent magazine, Wayne.

Rick Ferranti WA6NCX/1
Cambridge MA

P.S. Was that really you on .52 a couple of weeks ago, mobiling on the way to Tufts Radio? I moved out to this area a month ago for the even more dreaded occupation of graduate school, and found Tufts Radio to be an excellent and friendly place to spend my rapidly dwindling cash. As you may suspect, I have another article in preparation to help alleviate that situation!

Yep, 't was me . . . and thanks for the nice letter. — Wayne.

JAMMING

Congratulations on a fine magazine. Really enjoy your articles over *QST*; they are well-written and easy to understand.

Please find enclosed my check to cover my subscription and a tape.

I only have one complaint. I was listening around 3960 the other night and heard something that made me sick. K6GBG was in QSO with a friend and some jerk jammed him unmercifully. I am wondering what has happened to ham radio. I haven't yet seen a rig without a knob to change the frequency.

If you hams are as proud of your ticket as I am of mine, you will abolish this kind of activity on our bands (the jammer wouldn't even give his call letters).

Thanks again for a fine mag and a great hobby.

G. D. Ross WB7EBA
Medford OR

THE GREEN PHILOSOPHY

Here is my 3 year renewal to *73 Magazine*. At 18 dollars it is a real bargain.

Here also are a few comments that may be of interest to you. I must reluctantly say that *73 Magazine* is probably about the best of all the ham and "popular" types of electronics magazines. I wish I could say the same for its publisher. I often get the

feeling that *73* has, and perhaps always was, more of a personal journal than a vehicle for other hams than yourself, though it is that, too — even if not entirely intended that way. It's sort of a soapbox for you, on which to vent your feelings, espouse causes and screech at the top of your lungs on anything and everything that catches your attention and/or fancy.

As long as I'm at truth saying, I may as well add that there are times that you sound pretty much like a NUT! At other times you are a genuine All American Ham Hero. I've been in ham radio long enough to have followed your career from the start at *CQ Magazine*. You are, to say the least, unpredictable and ruthless to a large degree. You have had failures along the road but all have led to your current success, which is very probably the envy of many others who might have dreamed of doing the same that you have done, or, at least, in being in the same lofty position you now hold. You are much like that childhood poem: "When she was good she was very, very good; When she was bad she was horrid."

The big plus on your side is that you have made *73* the best all around ham magazine. So I am going to stick to *73* and let my subscriptions to all the others, including *QST*, drop. *QST* once was a marvelous publication, with the best in everything that the ham, or prospective ham, might ever want. The latest in construction — at all levels of advancement. A great sense of humor, especially in those once delightful "Strays." Unfortunately, the humor, as well as the quality of interesting articles, has pretty well disappeared. The pages of *QST* are filled with bland trivia that takes a great effort to justify in the minds of the average Mr. Ordinary Ham, like me. As for *Ham Radio*, it's OK, but I like *73* better. So for economic reasons I am discontinuing that publication. As for *CQ Magazine*, *the less said the better*. *Popular Electronics* and *Radio-Electronics* cater almost entirely to CB now, so they, too, will have to be discontinued.

I'm truly sorry to hear that you are eliminating most of the computer articles from *73*, in favor of starting up another publication, *Kilobaud*, in which they will all appear. Looks like I will have to do without them for the above stated economic reasons. $15 for that new magazine, plus the cost of *73*, is more than I can afford. So it will be *73* only from now on, much as I regret having to say that. And for the same reason I will be giving up *Byte Magazine*. There you have it. I am sure that my words reflect somewhat the same thoughts many other readers of *73* have about you and about *73*.

Mack O. Santer W2ZPW
Brooklyn NY

All of us were surprised to hear from you that we are eliminating computer articles from 73. As far as being a nut is concerned . . . that's okay with me . . . unless you can show me some sane person who has accomplished anything of real benefit to the world. My basic goal is to bring as much fun as possible to as many people as possible . . . and use this as a way to perhaps move the world ahead just a notch or two as a by-product. My dais is open for business. I use it to express my ideas, but I'm willing to step down for anyone with a piece to write, whether I agree or not. As far as I know, 73 has the only open pages for such matters. — Wayne.

PLEASE—NO AGC!

First, I'll bite again for another of your "rags" (3rd one).

We have cussed and discussed items before. Know you won't remember, but I wouldn't either in your place (too many to remember all).

I will get around to making copies of the USN code tapes I have one of these days. Too much going on here *all* the time. Please redo your code tapes on a machine without agc. The pumping is bothersome.

Add to your Ham Help column: We (The Wiregrass Amateur Radio Club) sponsor amateur classes via George Wallace Junior College. Novice classes run 10 to 12 weeks twice a year, starting September and March. General classes start in September and run 9 months if needed.

This is the way to operate such classes. The college takes care of everything except the actual teaching. The $10 fee keeps out the mildly curious. So far, after 3 Novice classes and 1 General, we have over 30 new hams in this area. Almost an exact double over 1½ years ago. Most of them are ex-CBers. We make sure the local CB crowd knows about the classes. Don't knock them — get them to join.

Roy Dancy
Dothan AL

CROSSED WIRES

I have just finished reading the letters portion of your magazine and was especially interested in the fellow who was giving up ham radio because of snobbishness.

I would like to advise him that I think he is misconstruing snobbishness with successful endeavors. I feel that when he visits some ham, most of whom are fair to well off, he is overwhelmed by the settings and the elaborate equipment, casts himself into an inferiority complex and cannot recover.

The amateur fraternity is on a fairly high plane and while most well-off amateurs do their best to make themselves understood, the evidence of comfortable living is self-evident and cannot be denied. Again, I consider this to be the underlying factor and it makes the newcomer of limited means very self-conscious. It cannot be helped and I know how he feels, for it is somewhat disconcerting to visit and see a lot of gear that goes to a sum of $5000.00 or better.

Maybe some hams puff up, but I am sure that it is pride more than aloofness, and I say that it is something that they earned. So, again, I think that the fellow that wrote in about snobbishness has some of his wires crossed. I know that I, for one, am overwhelmed by some of the new gear that some of my friends have, but I do not begrudge them; I only envy them and try to do better myself.

So that is my answer and I hope that maybe we can salvage this fellow.

Jack Golden WA2YPW
Portville NY

THE GOLDEN HELMET

As an editor, you should know better than to generalize in your statements. As a ham, you don't seem to be very knowledgeable regarding license classification.

You remind me of the Monsignor of an Irish parish who was very perturbed because one of his parishioners was baptized in a Polish church. I do suppose that a difference between 5 and 13 words per minute does emphasize a great intellectual difference in an individual whose cranial capacity seems to greatly exceed the capacity therein.

As a Technician, I couldn't care less regarding the phone part of the 10 meter band. As an amateur, I suggest that you read the amateur's code, parts one and four.

You remind me of the painting by Rembrandt, "The Man in the Golden Helmet," the old warrior dressed in a gilded uniform with only the memories of the past shutting out those of the future. The Technicians have committed much to the prestige of amateur radio, i.e., the 2 meter halo, TVI filters and many others.

Ham radio, because of attitudes like yours and your snobbish caste set, has taken a back seat to CB and has all but vanquished ham supply stores with fully stocked shelves. Fortunately there are still hams with a sense of human values who strive to build up and encourage the art rather than tear it down with their envy. Your name typifies your character.

John B. Swiencicki K2KMU
Parsippany-Troy Hills NJ

Right on. — Wayne.

A FREE RIDE?

Nearly every issue of *73* has at least one complaint about the code requirement (for amateur licenses) in the letters to the editor column. They remind me very much of the sort of complaints we get from students wanting to be relieved of graduation requirements (I teach at U of Ill.). They want to be relieved of the responsibility for language or math or science courses (the "hard ones"), but they still want a degree labeled "Liberal Arts." Their complaints invariably come down to the fact that they consider the courses difficult and want a free ride. Of course, they rationalize their objections by arguing that the courses are not "relevant." More often than not, these objections come from students too narrow to see beyond their immediate wants.

The principal justification for the amateur radio service is that it is a public service. The FCC study guides even indicate that one purpose of amateur radio is to provide a corps of qualified operators for the military and civilian communications systems in times of war. That — obviously — means operators qualified to use the Morse code, because that mode, more than any other, provides reliable communications at low power levels. Note that *all* the military services still use Morse trained operators. A ten Watt "Angry 109" can do yeoman service on CW in conditions that would put most phone stations out of service. Morse code is far from being, as one complaining letter argued, an outdated mode of communication. It works when others will not. I might also point out that most of our public service traffic nets are on CW and that MARS conducts many such nets.

It also is not true, as Wayne Green once argued, that few amateurs still use CW. If he would bother to come down on the CW bands, he would know that they are as crowded as the phone bands, but that most CW operators run 200 Watts or less. The CW bands tend to be a refuge for those operators who want to communicate, but who lack the money to buy the linear needed to compete on the phone bands. They're willing to work just a little harder than those at the top end of the band.

I find it interesting that so many who consider themselves bright enough to pass the electronic written are willing to admit that they cannot learn the alphabet. That is not a high price for the privilege of being an amateur radio operator. It may be a reasonable minimum. As a professor of economics once put it, "The cheaper a product, the less it is likely to be respected, and the more it is likely to be abused."

David G. Boyd WA9GBW
Collinsville IL

MORE WARC

The following are some of my personal observations. On September 29, 1976, a meeting was held between representatives of the CRTPB (Canadian Radio Television Planning Board) and DOC in Ottawa, for the purpose of discussing proposals of how to rearrange the frequency spectrum between 406 and 960 MHz. The submissions of this and further meetings will be used as a guide by the

Let's call this the "putting one's money where one's mouth is" department. For months now I have been telling you all to go forth and try to get your local CBers interested in becoming amateurs, getting them into training programs, inviting them to radio club meetings, offering to speak at CB "breaks," etc. Well, if you are going to try to meet some of the local CBers in your area, there is really only one place to meet them: on their band, their home territory – 11 meters itself. Why not? Eleven meter radios, the 23 channel variety, have been tumbling in price ever since the Commission announced that, as of January, CB would be expanded to 40 channels. In fact, the radio I purchased from one of the local department stores cost me under sixty dollars including slide-in lock mount and antenna with trunk lip mount and coax. I saw it advertised on TV one evening and ran out to purchase one before they were all gone. As it was, I had to wait for the next shipment as the demand was so great. The line at the counter stretched to the door, and this was a chain department store with many such locations. It would not surprise me to learn that this sale alone added over ten or twenty thousand new operators to 11 meters.

Anyhow, after unpacking the radio, I hooked it up to my allband long wire to see if I could hear anything. Hear anything? It was probably 100 deep on every channel other than 9, which is reserved as an emergency channel. Yet, in some uncanny way, a way that I still find hard to understand, people were actually having conversations and enjoying themselves. Squeaks, squawks and heterodynes everywhere, yet QSOs were going on – people interacting with people – very informal and a lot of obvious friendship. Everyone had a "handle," a pseudonym for personal identity, but what was surprising was that all but a few were using callsigns. When someone didn't use his legal callsign, he or she was "jumped upon" by many others. Hmmmmm . . . could it be that CB was changing? Could it be that average "Joe American" was now taking CB over from the hobbyist DXer and that, handles aside, CB was finally growing into what it was intended from its inception? Let's listen a while longer. An actual language barrier existed. I was finding it hard to understand a lot of what was being said; CB has its own "special language" much the same way that amateur radio has. Since I always believe that one should listen before engaging a PTT button, I took my own advice, sat back and garnered the necessary education.

Over the weekend I installed the locking slide mount and antenna on my '66 Galaxie, which in itself was no easy task, this being my favorite of our two autos even though it's older. I already had two such mounts for the two and 220 transceivers, a Motorola control head and a tone-pad to work around. Luckily, the CB radio was small and fit well just above the gas pedal . . . on the dashboard, that is, between the two meter radio and the Motorola speaker. A vacant spot was found on the rear fender of the driver's side and the lip mount discarded in favor of the regular 3/8" snap-in blind mount and adapter for the ASP type thread. Tuning the antenna took about 15 seconds using a Heath VSWR bridge to make the check that found the approximate midband VSWR at 1.2 to 1 and rising to 1.6 to 1 at either end (channels 1 and 23 respectively).

Can't tell you how strange I felt during my first 11 meter contact. It took a while to get used to the lack of formality, besides which I had no handle other than my name and callsign KKU4645. The strange feeling was short-lived though. By and large, the people one finds on CB are like the neighbors next door. Heck, in many cases, they *are* the neighbors next door. With few exceptions, the people I have met on CB have gone out of their way to make me feel at home with them. At first I kept my interest in amateur radio low profile . . . just being one of the guys . . . one of the voices on the radio. This didn't last. I became involved in many a contact with CBers talking about "moving up" (no pun intended) to amateur radio with specific interest in two meters and FM repeater operation. You have no idea of the impression it makes on a radio-oriented non-amateur to hear a demonstration of the coverage of a good FM repeater. Eyes light up . . . I have seen it happen! So far, the CBers I have met out here in LA who want to get their amateur licenses have no interest in CW, and cannot understand the need for it when all they want to do is talk. Many would be hams right now if not for that obstacle.

So far, in the few weeks that I have spent meeting the members of our local Citizens Radio community, I have been quite impressed by the dedication of many of them. Sure, they have their problems – jamming, malicious interference and, unfortunately, a bit of profanity on the part of a few "channel hogs." Basically, they suffer many of the same problems we face in amateur radio, only down on 11 meters the problems are greater due to the greater number of radios in use, the greater number of users of the spectrum, and therefore the chance for a greater number of "flaky" people to be part of the service. Simple math . . . the more individuals, the more chance for problems to show up. Interestingly, though, it seems that self-policing is starting to develop within the service, at least where I live; those who break the rules of CB etiquette are dealt with by their peers.

As things develop, and as I gather more information, I will pass it along. However, I am convinced that CB radio and its users are the best resource we have to tap for the growth of the amateur service. Many, not all, but many, CBers would like to get an amateur ticket if only amateurs would get off their "high horse" and offer a needed helping hand to those asking for it. It hurts when I hear about CB people going to local hams for assistance in that direction only to be met with a look of indignation and "get lost, who needs you" attitude. Put yourself in the other guy's place . . . how would you feel?

Oh yes, my lack of handle was also short-lived. While checking out the CB radio, I enlisted the aid of a fellow amateur, Charlie WB6SKM, who also possesses a CB radio. Charlie promptly christened me "The *73* Man" . . . well, what else?

While getting a CB radio as I did and taking amateur radio to the CBer was one way, there are other ways of getting the interested CBer to take the next step. A recent, well-publicized event here in Los Angeles was another way. Take an excellent producer-director team like Lenore (W6NAZ) and Bob (W6VGQ) Jensen. Add a well-known and talented emcee such as KTLA-TV personality Johnny Grant WB6MJV, an expert audio engineer like Bill Orenstein KH6IAF/6 with extremely fine equipment, and a bit of help from KHJ radio's Jim Davis WB0SQP/6 to set up and handle audio. Continue with an introduction using Dave Bell's new film, "Moving Up To Amateur Radio," which in itself has the ability to captivate an audience. Include a number of experts on different aspects of amateur radio

The Largest FCC Raid Ever

Federal marshals and FCC agents raided 19 locations in the Baltimore-Washington area early on the morning of October 27. Confiscated was over 65 thousand dollars worth of equipment used by outlaw SSB CBers. (See "In Pursuit of the HFers," Holiday '76 *73*.) It was the largest single raid in FCC history and capped a lengthy investigation by the Baltimore office in conjunction with the Laurel MD monitoring station. Similar investigations are ongoing across the country, according to FCC sources.

Among those charged with illegal operations were two Novice class amateurs and an alleged ringleader of Maryland CB SSBers. The agents, armed with search and seizure warrants, confiscated extensive membership lists giving call numbers and full names and addresses of the entire Maryland chapter. An FCC spokesman told *73* he expected some further investigations to grow from the lucky find. Station records taken in the raids are being scrutinized in an effort to identify every individual who may be involved and where equipment was purchased.

As illustrated by the accompanying photographs, amateur equipment made up the bulk of the FCC raids. Confiscated were a half dozen linear amplifiers, Heath and Yaesu transceivers, frequency counters, remote vfos, VHF HTs, beams and rotors, along with several ingenious CB rigs. One unit was reportedly set up like an ordinary CB rig with a frequency counter slung underneath. But when you switched on the ANL, the counter would indicate frequencies between 10 and 11 meters, and the delta tune became a vfo!

The FCC in Baltimore is conducting an inventory of all the equipment and taking technical measurements to determine exact frequency range and output. Serial numbers are being checked through local authorities to determine if any of the gear was stolen. (Amateurs in the Baltimore-Washington area who are missing gear would be wise to contact FCC Baltimore.)

All 19 CBers raided face federal charges carrying penalties of $500 dollars per day, per offense, and one year in prison and a $10,000 fine for the unlicensed use of CB or amateur radio equipment. Federal judges will decide what happens to all that equipment; it could go towards fines, be declared contraband, or end up on a government surplus list. In any case, it seems likely some of the equipment could go to charitable organizations, and show up on 20 meter SSB in the hands of a missonary, handling phone patches.

Incidentally, it was not the work of hams that led the FCC to the outlaws . . . instead it was the old Tennessee Valley Indians, plus what one FCC official termed massive interference to business radio, and local, state and Federal government radio users. Those are the same tracks that have led FCC teams to SSB outlaws in other parts of the country . . . and the same tracks that are being followed somewhere else as you read this, where would-be hams are taking the easy way onto the air.

Warren Elly WA1GUD
Associate Editor

Dead Within A Decade?

Part 97 of the FCC Rules and Regulations has been changed so much in recent years that most amateurs are not completely familiar with existing requirements. Even those of us who teach licensing courses have trouble keeping up to date with the latest changes. It is my opinion that very few of the recent changes will benefit amateur radio and that many of them will harm our service. Simply stated, I do not believe amateur radio is strengthened by weakening the rules and regulations under which we function.

It has long been obvious to most of us that the FCC does not intend to clean up the mess they have allowed to develop on the old 11 meter band. It appears to me that the FCC is hoping to alleviate some of the present CB problem by easing as many CB people as possible into amateur radio.

I believe our ARRL has been duped into helping the FCC clean up part of the CB mess. I can understand the League supporting a program to produce more amateurs; this is reasonable. However, I find it very difficult to believe that our League cannot see the danger to our amateur radio service. Listen to CB and make up your own mind how "beneficial" these people will be to amateur radio.

I have taught amateur licensing courses every year since 1948. I have had as many as 1,000 students at a time. I have had an increasing percentage of CB people in my courses since 1957 and the current percentage is usually about 30%. It has always been my experience that students with CB background are the least likely to stick it out and earn an amateur license; their dropout rate is about double over the rest of the group. Fortunately, we have had many ex-CB operators develop into extremely good amateurs who are a credit to the amateur radio service. Unfortunately, most of them have been unable or unwilling to shake their bad CB habits and this is bad for amateur radio. It has also been my observation that very few CB people are seriously interested in becoming amateur radio operators. The objectives, backgrounds, and philosophies of amateur radio and CB are radically different.

I do not believe we need to greatly increase the American amateur radio population to safeguard our frequencies at the 1979 World Administrative Radio Conference (WARC). Amateur radio has realized its most significant gains at times when we had very few amateurs. To the best of my knowledge, all WARC position papers were required to be submitted in mid 1976, so any upsurge in the American amateur population (between mid 1976 and the 1979 WARC) will not appear in those papers. Common sense further discredits the present "safety in numbers" approach. Basically, each country has an equal voice at WARC. This means that a country with hundreds of thousands of amateurs has the same voting strength as one with only a handful of amateurs. Since our country has one of the largest amateur populations in the world, it appears reasonable to me that the major objective should be to increase the numbers of amateurs in other countries. Our voting power at WARC will not increase one iota if we double or triple the number of amateurs in our country; please don't be gullible enough to believe otherwise.

My thoughts on this matter are summarized in this paragraph and I hope you will take the time to arrive at your own decision. I am opposed to recent FCC changes which I believe will seriously degrade our amateur radio service. I believe that FCC deregulation of amateur radio can lead to disaster. I do not believe the CB mess will be significantly reduced even if many of them are absorbed into amateur radio. I think the CB mess must be dealt with on its own by the FCC and that Congress should fund the FCC to do this major job. I am firmly convinced that converting any significant number of CB people to amateur radio will degrade our amateur radio service. I do not believe that a large influx of new amateurs is necessarily beneficial to amateur radio; it certainly cannot replace continuing quality performance of existing amateurs serving the public need.

If the present trends continue, I have no doubt that the amateur radio service (as we presently know it) will be dead within a decade. I hope this does not happen because I believe the amateur radio service is of great value to all the peoples of the world. If I did not believe this, I would not spend 20-30 hours per week helping new amateurs get started.

If you decide that our amateur radio service is in danger, please take action to eliminate the problems. I believe it helps to send ideas to the FCC, Senators, Representatives, House/Senate Communication Subcommittees, ITU/IARU, and ARRL. I have been writing for years and I would greatly appreciate some support. I do not believe it is too late to save our American amateur radio service, but it appears obvious to me that it will die if most amateurs fail to wake up and take action. We are communicators; let's pass the word before it is too late!!

Is There Life On Mars?

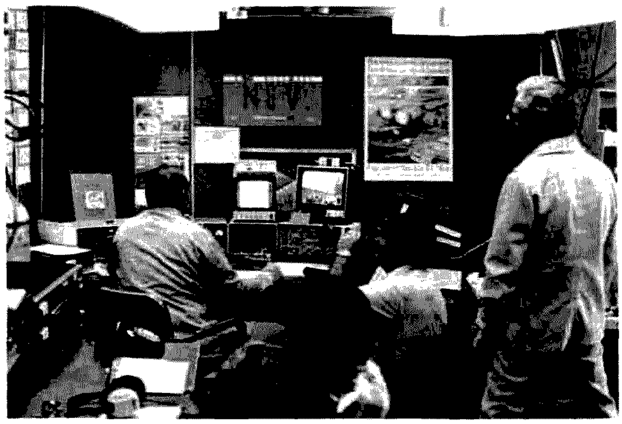
A special event call is issued by the Federal Communications Commission to commemorate some particular event or activity. N6V was such a call, issued on the occasion of the Viking mission to Mars. The significance of the Viking mission (to softland a spacecraft on another planet) warranted an equally significant callsign. N6V was the first modern day 1 x 1 call issued by the FCC to an amateur radio station. The Jet Propulsion Laboratory Amateur Radio Club, W6VIO, is proud to be its owner. We owe many thanks to the Commission for honoring our request.

N6V is the third in a line of commemorative calls issued to the JPL Amateur Radio Club. WP6JPL was for the Apollo 16 mission, and WS6MVM was for the Mariner Venus Mercury mission (Mariner 10). Over the period from June to November, 1976, N6V became one of the most significant special events ever to be undertaken by a single group of amateurs. The operation united our club more than ever before because a real team effort was required in order to build a completely new station from scratch, and then operate N6V over a five month period.

When the JPL Radio Club undertook this activity, we anticipated an event of a size comparable to our previous special events, 2000 to 3000 contacts. It soon became apparent that we had a tiger by the tail, and would have to work 10,000 or more stations to satisfy the tiger's hunger. Our existing station would not be able to handle the load because of small quarters, high electrical noise, limited antenna possibilities, and poor location (in a canyon two miles north of the Pasadena Rose Bowl). The club's long-term goal of a new trailer facility in a better location was now given a deadline for completion . . . June 18, 1976, the planned first day for N6V, which coincided with the orbit insertion rocket motor burn (45 minutes worth) for Viking I. Dick K6SVP was assigned as facility manager. The time was now March.

Final site plans were drawn and submitted by Glenn K6GHJ to the laboratory facility engineering people in May for approval, a surplus tower was obtained from the newly formed Goldstone Radio Club, WB6MXU, surplus RG254 hardline coax (7/8 inch diameter) was found in storage, a TH6DXX 6 element beam and Ham II rotor were purchased, and the race was on. Mr. Murphy reared his head by having the first spool of RG254 coax delivered Friday afternoon to the trailer location at the *bottom* of the rough, brush-covered, rattlesnake-infested hill on which the antennas were to be located some 650 feet up from the trailer. The work party, including five of the JPL Explorer Scouts working on the lab sponsored Project Sunfire for Pitcairn Island, was already scheduled for Saturday morning. There was no time to transport the spool of coax (which weighed several hundred pounds and was five feet in diameter) to the top of the hill, so we gallantly began pulling the coax *up* the hill. Without a doubt, 650 feet of RG254 gets very heavy, especially in the hot sun. The next run of hardline waited until the spool was transported to the top of the hill so we could pull the coax *down*. A second spool of coax was obtained in July and two additional runs of hardline were added. All went smoothly this time, until the wooden spool holding the coax disintegrated on the spool stands. The only solution was to unroll the entire spool by removing all the remaining spool wood and carefully unrolling the entire 1700 feet of coax along the ground. We could then pull the line down the hill.

Tower installation began six days before the deadline. Again, Murphy! Would you believe that when we met the fellow supplying our guy wires



Roy Neal K6DUE oversees NBC "Today" show filming.

KABC newsman interviewing Jim Lumsden WA6MYG.

All N6V transmissions were not SSTV. Here Bob Brodkin WA6TBH works CW under the watchful eye of the Viking project's biology man insignia.

and crimp sleeves at the top of the hill, and he went to open the trunk of his car, Murphy made the key not work? No amount of banging or twisting would open that trunk. Finally, we discovered that two identical cars had been parked side by side down below and that he had put the supplies in the right car, but driven off in the wrong car with the right ignition key! That wasn't the last of Murphy. He decided that one of the tower guy anchors would have to be set in solid rock! By the time we finished we had placed on top of that hill, aside from the 71 foot tower and tribander, a 2 meter collinear, an inverted vee for 40 and 80, and a 40 through 10 meter vertical.

In spite of it all, N6V went on the air at 1300Z, June 18, 1976, for the first operating period of five days. The basic plan was to operate for a total of forty days, divided into four periods coinciding with the four major mission events: Viking I orbit insertion, Viking I landing, Viking II orbit insertion, and Viking II landing.

The first period of five days netted 2250 contacts toward the goal of 10,000 and gave us the confidence that N6V would achieve its goal. We were very pleased at this initial achievement, since the station was manned almost entirely during non-working hours. Because we were a bit late getting the publicity out to some of the publications and missed the June issue, we were met with a bit of amazement and uncertainty as to the legitimacy of the call, but word spread pretty fast. Most worked modes were 20 CW, 20 SSB, and 2 FM, accounting for about 85% of the total contacts. The lowest count was 2 FM CW with one contact (what a surprise that contact was). Other bands and modes were worked, but seemed to be worked out pretty fast. Admittedly, our ears were not very good on 40 and 80 meters, mostly because those antennas for the first period were fed through 700 feet of RG9 coax with the consequent signal losses.

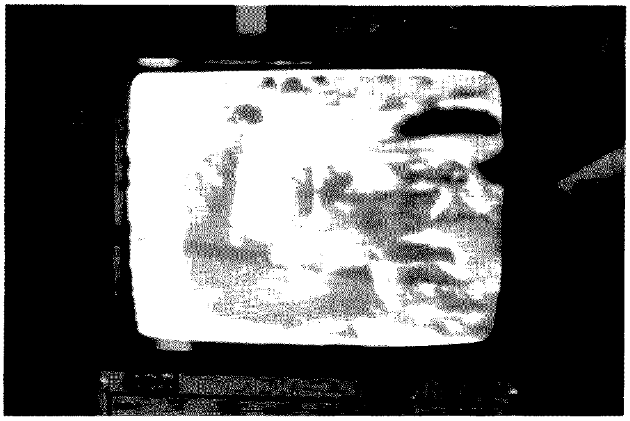
One of the biggest surprises while working 2 meters was being linked to the Kingman AZ 146.16/76 repeater some 600 miles away through a remote link on 146.52 simplex. Most of us were totally unaware that such a link existed. The next surprise was to hear that the entire link was controlled by Jerry WB6NQE while sitting on a diving board at Huntington Beach! Later connections into the remote link put us into locations like Las Vegas NV, El Paso TX, Santa Barbara CA and other points over the mountains north of us. Tremendous! Another highlight of two meters was to contact Bill Pickering, retired JPL Director and ex-Z28L, while visiting the shack. He was put in contact with the giant Goldstone 64 meter (210 feet diameter) antenna control station console which was being manned by one of the Goldstone Radio Club members. The link to the High Desert was made possible through WR6ALH, Rosemend CA, and WR6AFX, Table Mountain CA.

The reception that N6V received on the repeaters was tremendous and much appreciated. In most cases, N6V operation on repeaters was minimized during commuting hours. Initially, we had only two simplex and four repeater crystals; however, we soon realized that proper coverage of 2 meters required a synthesizer, which the club quickly purchased. It was like adding a new band, because we could now work all repeaters that we could reach, as well as other simplex frequencies. The Ensenada Radio Club, XE2BC, met us on one of the now available frequencies on sked one evening and we worked most of the guys in the Ensenada Club.

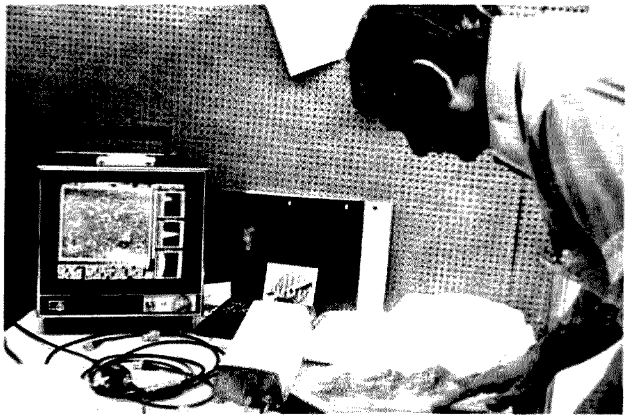
Novice response was, at first, one of bewilderment and disbelief. A three character call? That just did not fit the pattern! Frequently, the return call after a CQ would be to WN6NBV (N6V end to end, almost). As word got around, things got easier and the response got better. Ralph WB6YMF put in many hours at the Novice key.

The most fortuitous station worked early in the event was Mel W6VLH, who asked if we would be on SSTV. Our answer was negative, that no one in our club had the equipment. A couple of days later, we received a call from Robot asking what equipment we needed for SSTV operation and if they could loan it to us! Thus began one of the most wanted SSTV operations in the world. Jim WA6MYJ and Stan K6YYQ operated most of the SSTV (since the equipment was on loan we were sensitive as to its use). Pictures of Mars from both the Viking Orbiter and Lander were aired over N6V, occasionally into areas where there was little or no news coverage of the mission. A most memorable QSO was: "N6V de CZ2O. What are those pictures you are sending? They look like the surface of Mars!" "CZ2O de N6V. That's what they are!" We felt good that the pictures were recognizable. We are grateful to the JPL Public Information Office for providing us with the high quality photographs for our transmissions. We also had a direct video feed to the shack which allowed us to monitor and transmit some of the photos "live" from Mars as they were received here on Earth and processed by the computers. Jose YV5FBL, Caracas, Venezuela, was late to a ham club meeting when the XYL said that the Mars pictures were more important. Besides, he said the rest of the club would not believe him unless he had tapes to prove it. At least one ham, Bill W1PFA, was able to have his Polaroid photo of our transmissions published in the local newspaper, and then sent us a clipping. Bruce VK3VF sent impressive photos of a couple of pictures he received and also submitted to the newspaper. VE3AXC arranged to have TV news coverage live while receiving SSTV. Our local KABC-TV news team covered our operation in the Los Angeles area. Bob WBØJGJ got a story in his local Des Moines IA paper, which was picked up by the AP wire service, and culminated in many local TV news stories filmed in individual local towns (we haven't received all the video tapes yet) and also in a 5 minute report by Roy Neal K6DUE on the NBC "Today" show. As far as we could ascertain, that was the first time a film had been made from both ends of a QSO at the same time. That Roy's always thinking, but what a problem! We had to pick a station in one of several major cities in the US, establish a schedule with him, guarantee a contact at 8:00 am our time, all in less than 24 hours, so that Roy could schedule film crews in separate cities for the following day. Frank WB5SAG was our choice, and the filming was *1000%* successful. We're not sure who was flying higher — Frank or his patients (Frank is an anesthesiologist in Houston TX).

One contact, KC4AAB/M Reg 2 off the coast of South America, expressed more than the usual interest in the Viking mission progress during one of the SSTV operating periods. It turned out that the ship was an icebreaker on its way back from Antarctica with



The famous Mars ledge with a B or number 8 as it appeared from the Viking lander's camera prior to SSTV transmission.



The selection of hard copy pictures for SSTV transmission . . . here, Stan Brokl K6YYQ works near a picture coming from Mars.

several Viking project biologists on board. They had heard no news of Viking's success and were most appreciative of the information heard and vowed that before the next trip out they would have SSTV on board.

The station at N6V was not yet equipped for working OSCAR, so Skip W6PAJ came to the rescue with his mobile setup for working the satellites. Murphy caused an aluminum plate in the roadway to tilt and lodge under his van chassis as he drove by, literally launching all the equipment from the seats onto the floor. Remarkably, all equipment worked afterward. The only other problem encountered while working OSCAR was the high received noise level so that many stations returning Skip's CQ could not be heard. Several stations did get through, however, and we were very pleased that Skip braved the hill to set up on the mesa above JPL a few feet from the rattlesnakes (they *were* heard).

QRP was occasionally exercised, with George K6YGN braving the QRM most of the time. A 5/9 signal from Hawaii on 2½ Watts and 5/8 from the east coast on 1 Watt are not bad reports.

QSLing finally got underway about a month late when we received the cards from the printer (not entirely his fault) and we began filling the SASEs (first as promised). The hardest QSLs to deal with were those that included the SASE and a note saying, "Please send me the QSL card for contacting N6V." No time, date, band, or callsign! At the time we received that card, we had over 6000 entries in the logbook. Another QSL was a bit better; he at least included his callsign. Because we hope to QSL 100%, they will both receive their cards, just a bit later than hoped for. We received cards from several SWLers, and even one from an experimenter who copied SSTV. "Please QSL to W6VIO, Whiskey Six Viking In Orbit" became a catch phrase.

The effort involved in conducting an event the size of N6V is more than significant; it is major, as Jim WA6MYG found out. When volunteering to head the activity one year ago, the magnitude of N6V was not even dreamed of. Although painful (literally) at times to many who participated, the event was very successful, very satisfying, and enabled the JPLARC to realize one of its long term goals . . . a new station. Many friends were made both within and outside the club. This event will be remembered as a unique experience for many years.

Did it seem like a clique running N6V? All who came and participated became a part of the "clique." The list below cannot possibly cover all contributions of every individual; N6V was a team effort and everyone helped in many areas: Jim Lumsden WA6MYJ, N6V Activity Chairman; Dick Piety K6SVP, Facility Manager & Operator; Stan Brokl K6YYQ, Facility & Operator; Ralph West WB6YMF, Facility & Operator; Chuck Weir W6UM, Equipment & Operator; Norm Chalfin K6PGX, Photographer & Operator; Merril Burnett K6BER, QSL Manager; Glenn Berry K6GHJ, Facility; George Williamson K6YGN, Operator, QRP; Jack Patzold KDT6574, Facility & Operator; Warren Dowler KNX8341, Operator; Skip Reyman W6PAJ, OSCAR, Gordon Crawford WB6DRH, Publicity; Jim Longthorn WA6KPW, Operator; Rich Ward WA6VOG, Operator; Merv MacMedan W6IUV, Operator; Bob Brodkin WA6TBH, Operator; Bob Biswell W6MZR, Operator; Stan Sanders WB6MPM, Operator; Joe Berry WA6FCE, Operator; Stan Hench WB6JMP, QSL Design; Bill Carpenter WA6QZY, Video Feed; Waldo Brown W6QWC, Video Feed; Jay Holladay W6EJJ, Trustee.

Beating the Hamburglar

If crime statistics prove correct, nearly all of us can expect to have that prized mobile rig forcibly removed sometime in the near future. It can happen in a parking lot, your own driveway, the service station, or right outside on club meeting night.

The best way to be sure that you don't become a victim of Midnight Electronics Supply is to remove the rig and all markings that indicate the presence of radio equipment. This may also include the extremely unpalatable task of returning those callsign plates to your local registry.

The dyed-in-the-wool mobile operator realizes that no matter how many precautions are taken, it's often next to impossible to completely hide the fact that gear is contained within. So here are a few dos and don'ts for hams that just might keep the cost of the hobby within reasonable bounds.

Do keep your bill of sale in a safe place at home, not in the car.

Do engrave your driver's license number and state on both the inside and outside of the rig.

Do install a quick disconnect system. When leaving the car, take the rig with you or place it in the trunk. Out of sight, out of mind.

Do make sure that you have adequate insurance coverage for your gear. The insurance situation is worth an article by itself. Remember that even though you have homeowners or comprehensive auto theft coverage, there may be exclusions on radio gear as well as high deductible and depreciation clauses.

Don't try to hide the rig with a jacket or blanket. It only arouses curiosity.

Don't leave the car unlocked. Although it sounds like a silly statement, the vast majority of ripoffs happen through the car being inadvertently or purposely left unlocked. Most insurance companies won't pay claims unless there is proof of forced entry.

Don't try to booby-trap your gear. Not only is there a chance that you or a loved one might be injured, but you face the possibility of a lawsuit for assault. (Don't laugh, it really does happen.) For example, if a kid sees your booby-trapped 2 meter rig and goes for it thinking it's CB, WHAMMO! His family can nail you under laws governing what's called an "attractive nuisance." Juries are known to be sympathetic to the kid in these cases and you could be out a few years' pay in one fell swoop.

If, despite the above precautions, you still become victim of the ripoff, here are a few steps to follow:

1. Make sure you really suffered a loss. The gear could be sitting back on the kitchen table or hidden away in the shack. This can be *extremely* embarrassing.
2. Call the local police. Tell them what happened, what was taken, and the identification markings on it. If an item marked with your driver's license

Looking West

from page 10

OSCAR. Give all this enough prepublicity and you have the makings of an entertaining evening to present to the general public and particularly the Citizens Service operators of the area. This was exactly what was done the evening of September 15, 1976, when the San Fernando Valley Radio Club, in cooperation with the ARRL, sponsored the first "Wide Wonderful World of Amateur Radio" evening subtitled "Everything you always wanted to know about amateur radio but were afraid to ask."

Johnny was at his best that evening, keeping things moving right along, while at the same time being truly entertaining. It was obvious that for him the evening was a labor of love. The pitch of the program was kept high, moving from topic to topic, explaining in progression the many diverse aspects of amateur radio and the people therein. There were demonstrations of slow scan TV, repeaters and autopatch, talks on RTTY and public service. In all, the entire gamut of what amateur radio is all about was covered in this fast-paced two hour presentation. It took a lot of planning, a lot of giving on the part of those involved and, most of all, a feeling on the part of all that what was being done would indeed benefit amateur radio. In the end, somewhere between two and three hundred local residents, many of them CBers, got a bit of insight into the world of the radio amateur and what an amateur could do within the scope of his interest. In all, it was an evening that epitomized the real amateur radio and on a fairly large scale shared it with the non-amateur.

If I had to pick one moment of that evening to call a highlight, I suspect it would be the story told by Lee Goldberg WA6AVP explaining how, for her, amateur radio was the therapy needed to aid in recovery from a serious illness. She told how, in the process, she went from non-amateur to Advanced class in a very short time span. These were moments that held everyone spellbound. Lee's story is one of beauty and dedication, and is an inspiration to set one's sights toward higher goals. Working hand in hand with her husband Bob WB6OFO, Lee not only conquered the after-effects of a serious stroke, but in the process has come to symbolize the important part that amateur radio can play in avenues never explored. Lee is not only a credit to her own personal initiative to conquer an obstacle put in her path, but is also an opener of new horizons for others to seek. She has given a very special new meaning to amateur radio.

If you have been thinking about trying such an event, but have feared that it might fail, fear not! This first was indeed a success and hopefully more such evenings will follow with other members of the amateur community emulating what was begun one warm September evening in Los Angeles. The first "Wide Wonderful World of Amateur Radio" evening will long be remembered by all who attended. Who knows, it may even get us a few new amateurs, and that would be the crowning glory. Yes, we were lucky to have a talented professional crew to start off this type of event, but it's nothing that any amateur radio club cannot emulate on either a larger or smaller scale, with or without the professionals. All it really takes is caring a bit as to whether there will be any amateur radio after the 1979 WARC Geneva conference. Those within our amateur community will pick up the ball and carry it. Is that someone you?

A REPEATER FOR ALL SEASONS

We have repeaters dedicated to many diverse aspects of our hobby/service. There are emergency calling systems dedicated to RACES and AREC type operation, autopatch systems whose prime purpose in life seems to be letting the XYL know that you are pulling into the driveway, club repeaters that, open or closed, are intended to act as an intercom between members of a given radio club and, lest we forget, the good old standby, the simple rag chew type of open system available day and night for anyone to use as long as they operate within the scope of their license privilege. Did I say anyone? Pardon my blunder. Well, though many a system professes to be open to all, in many cases one group does not always get a warm welcome. What group? Why, the "youngster," of course. You know, that group still in school, ages 15 or so and younger, who happen to hold amateur licenses but find it quite hard to develop the same type of lasting friendships on repeater systems that we in the next generation up seem to take for granted.

Admittedly, there is an interest difference between the generations, but must there also be a different set of standards imposed on the younger ham? Must they be relegated to 40 CW when they too have a need, and indeed, by the fact that they have passed the same test as you and I, a *right* to share the same spectrum? And that includes repeaters! At long last someone is about to put into operation a repeater system that will have one specific purpose for its existence: to give the younger generation of amateur with an interest in VHF and repeaters a place to converse with his peers. In a nutshell, that's the avowed prime purpose of WR6AKG and its father, Keith Glispie WA6TFD.

Keith, not that long out of school himself, noted that while virtually every special interest group had a repeater and a format upon which to interact, the younger generation of amateurs in Los Angeles had no such forum. As Keith tells me, about a year or so ago the whole idea began to take shape. Why not a repeater for this group? More specifically, why not a repeater that was designed to serve the need for school amateur radio clubs all over Los Angeles and surrounding environs, as well as their individual members? What a showplace to use as a tool to convince the public school CB operator that a whole new world exists in amateur radio. Not long ago, when the callsign WR6AKG arrived in the mail and a Pye Communications FM-50 high band repeater became available. Keith's dream began to become more of a reality.

As word of Keith's plan began to leak out, it began to have a rather positive effect on many members of the local FM community, including SCRA's Bob Thornberg WB6JPI, who quickly assigned Jim Hendershot WA6VQP of the Technical Committee to handle the coordination for this system and at least try to expedite the matter. With virtually every two meter channel now coordinated and in use, finding a channel for this project would not be easy, but it is not an impossible task. In fact, since it might be of interest to readers, we will be following the SCRA coordination of WR6AKG starting in this issue to show you exactly how the SCRA operates — sort of two stories in one.

About four weeks ago, after making the decision to put up WR6AKG, Keith contacted the SCRA and told them briefly of his intent. By return mail, he received an "RFC" (Request For Coordination) form that he filled out and returned to the SCRA. Normally, such a request would be placed before a meeting of the Technical Committee for action, but in this case certain parameters of the proposed repeater system called for special consideration on the part of the SCRA. Therefore, Bob directed Jim to look at all aspects of the matter, consider the parameters under which the system as proposed will operate, compare this with the environmental impact that such a system will have on any co- or adjacent channel users, and from this make a recommendation to the Technical Committee as to where on two meters to put WR6AKG.

Very shortly, Jim will have to report back to Bob and the rest of the Two Meter Technical Committee (SCRA has a separate 220 Technical Committee). If they agree with Jim's findings, then Keith will be issued a 90 day "Test Sanction," during which he will place WR6AKG on the air. While it's in operation, he will work with his adjacent channel users, co-channel users, if any, and the SCRA Technical Committee to solve any and all problems that might arise due to this system's establishment. During this time, Keith, like any other test sanctionee, will be obliged to file written reports with the SCRA Two Meter Technical Committee; any co-channel or adjacent channel users will also be given a chance to file any information they feel pertinent about the effects that the new repeater is having on their already existing system. From this myriad of information, the SCRA will make a final decision as to whether AKG will remain where now sanctioned permanently, be moved to a new assignment or perhaps moved to 220, or should no possible final "home" be possible, be requested to cease operation. As this all progresses, we will keep you informed. This, though, is what good competent technical frequency coordination is all about. Not just finding an "open slot" in which to put another system, but rather taking into account all aspects of the proposed new system, its effect on already established systems, the effects of surrounding terrain, the effect that the users of any new system will have on existing systems adjacent to it, and many other parameters that could fill an entire column. These are just a few of the items that Jim is currently investigating in his attempt to find a home on two for WR6AKG. How successful will Jim be? We will continue this next month.

Finally, a few comments of my own about the past two columns

The beautiful story of amateur radio as a therapeutic tool described by the person who used it as such — Lee Goldberg WA6AVP, with OM Bob WB6OFO.

CONTESTS

Editor:
Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

ARRL VHF SWEEPSTAKES
Starts: 1400 Your Local Time
Saturday, January 1
Ends: 2400 Your Local Time
Sunday, January 2

Complete rules for the 29th VHF Sweepstakes can be found in the December issue of *QST* (please check for any last minute changes in the rules). Briefly, the rules are as follows:

All amateurs operating on or above 50 MHz are invited to participate. Contacts between stations in different time zones can be counted only when the contest period is in progress in both zones. Foreign stations may only work stations in ARRL sections. Crossband work and retransmitted signals (repeaters) are not allowed. Contacts with aircraft mobiles cannot count for section multipliers.

EXCHANGE:

QSO number, precedence (A = less than 50 Watts input power), your call, CK = last 2 digits of year first licensed, ARRL section or country.

SCORING:

Score one point for each exchange sent and each received (max. 2 points per QSO). Each section counts as a multiplier only once regardless of band and no more than one foreign country may be claimed as a section multiplier. Yukon-NWT counts as a separate multiplier. Final score is the total number of QSO points times the total number of sections plus 10.

LOGS:

Official logs may be obtained from ARRL. Send contest logs and summary sheet to: ARRL, 225 Main Street, Newington CT 06111.

QRP – WINTER – CONTEST
Starts: 1500 GMT
Saturday, January 15
Ends: 1500 GMT
Sunday, January 16

The contest is organized by the DL Activity Group – CW. Work 15 hours maximum during the 24 hour contest period, with no more than two pause periods. Select up to 5 bands from 160 to 10 meters. General call is "CQ QRP TEST." A station is not handicapped if CO/VXO control *and* VFO control are used on the same band or the input power of a commercial rig is reduced to below 2.5 Watts. QRO stations – same rules, but work only QRP stations and sign as ". . ./QRO"; scoring is the same.

EXCHANGE:

RST, QSO number, and input (1 to 9). Add "x" if transmitter is CO or VXO-controlled. Example: 579 005/8x.

SCORING:

QSOs with all stations are valid unless running QRO; then only QSOs with QRP stations count. Contacts with your own country count 1 point, own continent = 2 points, DX = 3 points, and score 3 additional points for a QSO with another QRP station (4-6 points). Score additional handicaps as follows: 1 handicap point for each station using below 3.5 Watts input or crystal controlled transmitter. Maximum handicap is 4 for any QSO. Both stations multiply QSO points times the handicap points plus one (QSO points x 5 maximum) to find total QSO points for that contact. Multipliers are as follows: own continent = 1, DX = 2 points per band and country according to the latest DXCC list, but call areas in JA, PY, VE, VK, W and ZS count extra. Final score is total QSO points (including handicap points) times the total multiplier.

LOGS:

Send entry including a "mini-log" to: Hartmut Weber DJ7ST, D-3201 Holle, Kleine Ohe 5, Fed. Rep. of Germany. Logs should be sent no later than February 15, 1977.

CLASSIC RADIO EXCHANGE
Starts: 1800 GMT
Sunday, January 30
Ends: 0100 GMT Monday, January 31

Formerly "Nostalgia Radio Exchange," the contest is sponsored by the Southeast Amateur Radio Club, K8EMY, and is open to all. A classic radio is any equipment built since 1945 but at least 10 years old, an advantage but not a requirement in the Exchange. Object is to restore, operate, and enjoy older equipment with like-minded hams. General call is "CQ CX" on CW and "CQ Exchange" on phone; no AM phone below 21 MHz. The same station may be worked on each mode on each band.

EXCHANGE:

Name, RST, state, province or country, transmitter type (send PA tube if home brew, i.e., "6L6"), and any other interesting pleasantries.

FREQUENCIES:

CW – up 60 kHz from low ends.

Phone – 3910, 7280, 14280, 21380, 28580.

Novice – 3720, 7120, 21120, 28120.

SCORING:

Add the numbers of different transmitters, states/provinces/countries for each band. Multiply by total number of QSOs and then multiply that total by Classic Multiplier: total years old of your transmitter and receiver (if transceiver, multiply years by 2). Different equipment combinations may be used; figure scores separately for each and combine for total score.

ENTRIES:

Send logs, comments, pictures, etc., to: Stu Stephens W8KAJ, 2386 Queenston Rd., Cleveland Heights OH 44118. Certificates will be awarded for highest score, longest DX, most equipment combinations, oldest equipment, and "unusual achievements."

NEW HAMPSHIRE QSO PARTY
2000Z February 12 –
0500Z February 13
1400Z February 13 –
0200Z February 14

The New Hampshire QSO Party, sponsored by the Concord Brasspounders, Inc., W1OC, is held to promote the Worked New Hampshire Award. Operating periods are 2000Z Feb. 12 to 0500Z Feb. 13, and 1400Z Feb. 13 to 0200Z Feb. 14. Stations may be worked once per band per mode. New Hampshire stations may work each other. NH stations send RS(T) and county. Out-of-state stations send RS(T), ARRL section or country. NH stations score 1 point per QSO times the number of ARRL sections plus countries plus NH counties. Others score 5 points per NH QSO times the number of NH counties.

FREQUENCIES:

CW – 1810, 3555, 7055, 14055, 21055, 28130.

Phone – 1820, 3935, 3975, 7235, 14280, 21380, 28575.

Novice – 3730, 7130, 21130, 28130.

VHF – 50.115, 145.015, FM simplex (no repeaters).

AWARDS:

Top scorer in each NH county, and top scorer in each state, province, and country (50 points minimum). Additional certificate available for confirmation of all 10 NH counties. Send logs, summary and check sheets to: Concord Brasspounders, Inc., C. Halloway, 9 Via Tranquilla, Concord NH 03301. Mailing deadline is March 14, 1977. Include business size SASE for results and/or award.

QRP AMATEUR RADIO CLUB INTERNATIONAL INC.
1977 ANNUAL APRIL QSO PARTY
Starts: 2000 GMT Saturday, April 2, 1977
Ends: 0200 GMT Monday, April 4, 1977

This contest is open to all amateurs and all are eligible for the awards.

EXCHANGES:

Members: RST/RS. State/province/country, QRP number. Non-member: RST/RS. State/province/country, power.

SCORING:

Stations can be worked once per band for QSO and multiplier credits. Each member QSO counts 3 points. Non-member QSO 2 points. Stations other than W/VE count as 4 points.

MULTIPLIERS:

More than 100 Watts input power – x1; 25-100 Watts input power – x1.5; 5-25 Watts input power – x2.0; 1-5 Watts input power – x3.0; less than 1 Watt power – x5.0.

Score equals QSO points x total number states/province/countries PEP band x power multiplier.

FREQUENCIES:

CW: 3540, 7040, 14065, 21040, 28040.

SSB: 3855, 7260, 14260, 28600.

Novice: 3720, 7120, 21120, 28040.

All freqs plus or minus 5 kHz or so to dodge QRM.

CALENDAR

Jan 1 - 2	ARRL VHF Sweepstakes
Jan 15 - 16	QRP – Winter – Contest
Jan 30 - 31	Classic Radio Exchange
Feb 5 - 6	ARRL DX Contest – Phone
Feb 5 - 13	ARRL Novice Roundup
Feb 19 - 20	ARRL DX Contest – CW
Feb 19 - 20	YLRL YL-OM Contest – Phone
Mar 5 - 6	ARRL DX Contest – Phone
Mar 5 - 6	YLRL YL-OM Contest – CW
Mar 19 - 20	ARRL DX Contest – CW
Mar 26 - 27	CQ Worldwide WPX SSB Contest
Apr 12 - 13	YLRL DX-YL to Stateside YL Contest – CW
Apr 26 - 27	YLRL DX-YL to Stateside YL Contest – Phone
July 2 - 3	QRP – Summer – Contest
Aug 20 - 21	NJ QSO Party

Note: ARRL contest dates are tentative, as they were not officially announced at the time of this writing (check *QST* for the exact dates).

Also, don't forget to send early for ARRL logs and entry applications for DX and Novice Roundup contests.

METHOD OF CALLING:

Call: CQ CQ CQ QRP DE (callsign).

AWARDS:

Certificates to the highest scoring station in each state, province or country. Other places will be given depending on activity. One certificate for the station showing three "skip" contacts using the lowest power.

LOGS:

Send full log data, including your full name, address and bands used, plus equipment, antennas, and power used. Entrants desiring results please enclose a #10 SASE to receive result sheet. Logs must be received by May 30, 1977 to QUALIFY. Send all logs and data to: E. V. Sandy Blaize W5TVW, 417 Ridgewood Drive, Metairie LA 70001.

THE MELVIN JONES 77 CONTEST

SPONSORSHIP:

The contest was instituted by Santos Lions Club Ponta da Praia. It will be supervised by the sub-directory of Labre of Santos and the CW Praiano Group. It will be held every year during the second weekend of January for CW and during the third weekend of the same month for SSB.

AIMS:

The contest intends to provide contact among the largest possible number of ham operators all over the world and to proportionate the International Interchange among Lion ham operators.

PERIOD:

CW section – Beginning Saturday 8-01-77 – 00:00 GMT = 21:00 hours Brazilia time 7-01-77, to Sunday 9-01-77 – 24:00 GMT = 21:00 hours Brazilia time 9-01-77.

SSB section – Beginning Saturday 15-01-77 – 00:00 = 21:00 hours Brazilia time to Sunday 16-01-77 – 24:00 GMT = 21:00 hours Brazilia time.

Single operator stations can only operate 30 hours out of the 48 hours of the contest. The minimum obligatory 18 hours of the QRT in the contest can be divided up into 4 periods at any moment during the course of the contest and must be clearly pointed out in the logs. The multi-operator stations may operate 48 hours.

BANDS:

The contest activity will be in the 3.5, 7, 14, 21 and 28 MHz bands.

COMPETITION TYPES:

a) Single operator, any band; b) Singe operator, just one band; c) Multi-operator, any band.

MESSAGES:

For Brazil, the CW bands will be constituted of the RST followed by the States abbreviation, and for foreign stations only RST. Example: PT 2 JB 559/DF – DJ 2 MN 599 – ZS 1 WA 599. CALL: CQ Contest Melvin Jones.

For Brazil, SSB will be constituted of the RS followed by the States abbreviation, and for foreign stations only RS. Example: PY 2 LB 59 GO – PY 2 BOR 59 SP – W 2 PV 59 – LU 1 BB 59. CALL: CQ Contest Melvin Jones.

POINTS:

a) QSOs with stations of different continents shall count 3 points in the bands at 14 and 2 MHz and 6 points in the 3.5, 7 and 28 MHz bands.

b) QSOs with stations in the same continent shall count 1 point in the band of 14 and 21 MHz and 2 points in the 3.5, 7 and 28 MHz bands.

c) Contacts between stations in the same continent are allowed but shall count only 1 point.

MULTIPLIERS:

All the Brazilian States and Territories and all countries worked will be counted only once; even if worked in different bands they will be multiplied by the total number points.

AWARDS:

a) The ham operator who attains the greatest number of points in the world on CW will be granted the International President Lions Club Trophy, and the one who gets the greatest number of points on SSB will be granted the District L-16 Governador Trophy together with special diploma for each mode: CW or SSB.

b) A trophy will be granted to all those who get the most points on each continent. To second place, we will give a medallion containing the Santos Ponta da Praia Lions Club inscription. Diplomas will be awarded for each mode of operation: CW or SSB.

c) The Brazilian ham operator who gets the greatest number of points on each mode will be granted the Santos Lions Club Ponta da Praia Trophy. The second place will be given the Lions Medallion.

d) The country which gets the greatest number of points among all participant countries will be granted permanent possession of the Melvin Jones Trophy.

DIPLOMAS:

a) Every ham operator classified in the first and second places in each country and also Brazilian States and Territories will be granted a special diploma mentioning the classification.

b) The other foreign and Brazilian ham operators taking part in the contest will receive a diploma of participation once they get a minimum of 500 points or 50 contacts.

c) All radio receivers from all over the world including the Brazilians who send their reports mentioning bilateral contacts will be granted special diplomas. For that a number of 25 contact reports is required.

REPORTS:

a) The time must be indicated in GMT (= Brazilian time plus 3 hours). The periods of 18 hours (minimum) of QRT must be clearly indicated in the log.

b) Use one log sheet for each band.

c) All the participants must attach to their log a QSL card addressed to Santos Lions Club Ponta da Praia.

d) A summary must be sent postmarked no later than 30 days after the contest. They must be sent to: Ham Operator Contest Commission, Santos Lions Club Ponta da Praia, P.O. Box 11, 11100 Santos SP Brazil.

DISQUALIFICATION:

Violation of the ham operator regulations, non-ethical conduct, QSOs in duplicate in the same band and non-participant prefix can cause a loss of points. The acts and decisions of the Contest Commission will be decisive.

INTERNATIONAL SHORT WAVE LEAGUE

If you work a fair amount of DX and try to QSL most, you may be interested in the International Short Wave League, 1 Grove Road, Lydney, Glos, GL15 5JE, England. Besides the monthly newsletter giving DX operating notes, contests, awards, etc., you also get full use of their two-way QSL bureau. Their bureau does not require SASEs and incoming QSLs are mailed at regular intervals. The membership fee for US hams is $10 per year. The ISWL also provides a translation service, a correspondence bureau and a large selection of awards:

Century Club – For confirmed 100 countries; stickers each additional 25.

Heard All Continents – Veri-

fied contact with 10 stations in each of the 6 continents.

Heard All States – Verified contact with 48 continental US states.

Commonwealth Award – Verified contact with 50 different countries within the British Commonwealth of Nations.

European Award – Verified contact with 50 different countries within continent of Europe.

Pacific Ocean Award – Verified contact with 45 different countries which have at least a part of their coastline on or in the Pacific Ocean.

Zone Award – For working 25, 50, and 75 ITU zones.

5 Band DX CC Award – For working 100 countries on 5 bands.

MARAC AWARDS

Any hams interested in county hunting or information on the Mobile Amateur Radio Awards Club (MARAC) should send a large SASE with 3 first class stamps to Bertha Eggert WA4BMC, P.O. Box 6811, Southboro Station, Lake Worth FL 33405. Or, try listening to one of the county hunter nets on 14337 (from 1300 GMT daily), 3943 (from 0100 GMT daily), 7237 occasionally, or the CW county hunter nets on Wednesday evenings 2300 GMT on 7055, Saturdays at 1400 and 2000 GMT on 14070, and Sundays at 1430 GMT on 7055. More information on CW county hunting can be obtained from K1ZFO who publishes a monthly newsletter for $2.40 per year. The awards available from MARAC include:

Cliff Corne Jr. K9EAB Memorial Award – For working holders of the USA-CA All Counties Award; in classes of Basic = 10, C = 25, B = 50, A = 75, AA = 100. Basic award $1.00, seals for SASE.

Associate Award – For working charter, regular, or associate members of MARAC for a total of 100 points for the basic award with seals for 250, 500 and 1000 points. Regular members count 2 points each and associates count 1 point each. Fee: $1.00.

M-50-M Award – For working mobiles in all 50 states; original award for 48 states, seals for 49 and 50. Special seal for working all states mobile to mobile. Fee: $1.00.

YL Mobile Award – Work 5 or more YL mobiles in a total of 50 different counties. Seals for 100, 200, and 500 counties. Plaque for 1000. Fee: $1.00.

MARAC DX Mobile Award – For working 25 DX counties while operating mobile. Seals for 50 and 75 counties; plaque for 100. Fee: $1.00.

MARAC Last County Award – First category: Basic award for any station giving last county to finish a particular state. Seals for second, third, and fourth times. Same county and state may be given in each instance. Send application and mobile reply card signed by recipient stating facts for verification. Award can be repeated. Basic fee: $1.00. Second category: Basic award and plaque to any station giving last county to finish ALL states. Fee: $7.50.

Merit Award – Free to any amateur upon recommendation of any MARAC member for outstanding service to amateur radio.

Worked All Counties USA Second Time – For working all counties in the USA a second time!

MARAC Mobile Award – Category 1: To any mobile for giving out at least one county in each of 15 states; seals for 25, 35, and 45 states: plaques for 48, 49 or 50. Category 2: To any station for working the same mobile one time in 15 states; seals for 25, 35, and 45; plaques for 48, 49, and 50. Category 3: To any mobile for giving out 100 different counties; seals for 250, 500 and 1000; plaques for 1500, 2000, 2500, 3000, and 3075. Category 4: To any station for working same mobile in 100 different counties; seals for 250, 500, and 1000; plaques for 1500 2000, 2500, 3000, and 3075.

All award applications should be addressed to: MARAC Awards Chairman, 602 Jefferson St., Lee's Summit MO 64063. Further information can be obtained from WA4BMC as noted earlier.

NC COUNTY AWARD

Basic award $1.00; additional awards for SASE. Classes: D = 30; C = 54; B = 75; A = 100. Send GCR list of stations worked and confirmed to: Alamance Amateur Radio Club Inc., P.O. Box 503, Graham NC 27253.

JUMPING OFF PLACE AWARD

Honoring Independence MO Award; free of charge for working Independence MO stations for points. 5 points total needed. WBØAEW, WBØGYR and WØQWS count 2 points each; others are 1 point each. Apply to Jerry Dowell WBØGYR, 14412 37th St., Independence MO 64055. No date, time or mode limitations.

THE MAPLE LEAF AWARD

Available to both amateurs and SWLs, the award consists of 2 parts – a flag parchment diploma and a Canadian Maple Leaf Flag lapel pin. The award is for working (or hearing) and confirming Canadian amateur radio prefixes. QSLs must be in your possession. A GCR (certified list) must accompany your application. QSLs should not be sent unless requested. Classes: 1. 30 or more different Canadian prefixes; 2. 25 different Canadian prefixes; 3. 15 different Canadian prefixes.

A special plaque award will be issued free of charge to any radio amateur who works and confirms 50 or more different Canadian prefixes. All contacts for all classes must be made after January 1, 1965. Send application, GCR, and 10 IRCs or $1.50 (or equiv.) to the awards custodian: Mr. Garry V. Hammond, Geography Department, L.D.S.S., 155 Maitland Ave., S. Listowel, Ontario, Canada N4W 2M4.

Prefixes can come from: CF, CG, CH, CI, CY, CZ, VA, VB, VC, VD, VE, VF, VG, VO, VY, XJ, XK, XL, XM, XN, XO, 38, 3C and any later ITU assigned callsigns.

CHN MOBILE ACHIEVEMENT AWARD

Issued in 3 different categories: 1. For working mobiles in counties of any one state; 2. For mobiles giving out counties of any one state; 3. For working same mobile in counties of any one state.

BONANZA – The applicant gets award for working same mobile and the mobile gets award free as gift of applicant for giving out counties to same station.

Classes: A = all counties of a state: B = 2/3; C = 1/3.

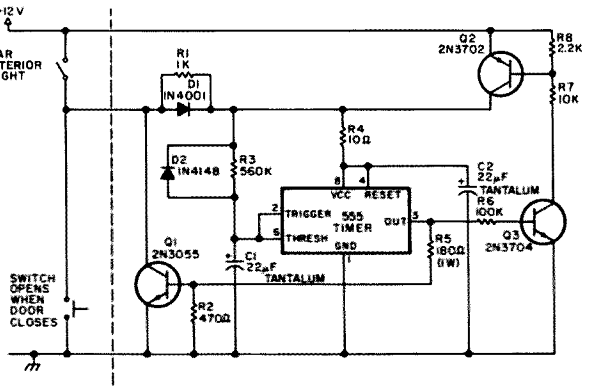
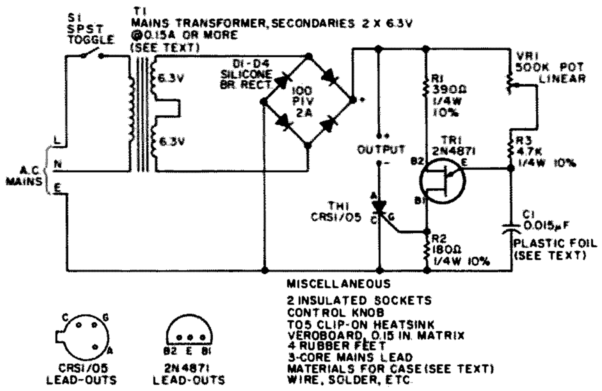
Circuits²

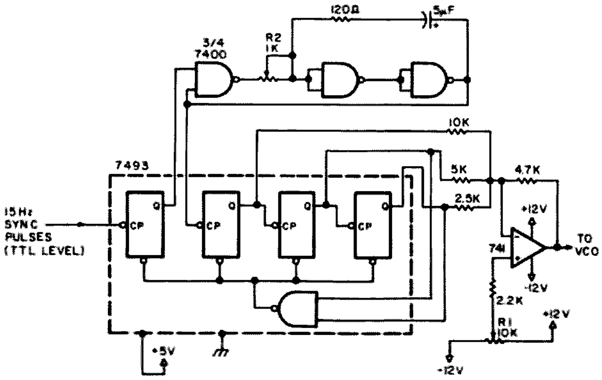
Want a free copy of any 73 publication? Sure you do. Just send in your favorite circuit, or even one that you don't especially like. If we print it, you take home the book of your choice.



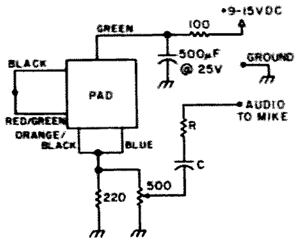
This time delay circuit is easily adaptable to turning off an alarm system and resetting it after a preset period. The values shown will keep the load activated for about 10 seconds, but can be adjusted for values up to many hours. Reprinted from LIMARC Log.

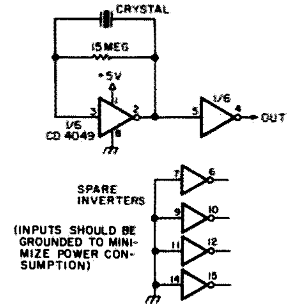


This circuit enables you to use a 12 V dc motor off the ac power line. The motor must be rated at 1 Amp or less. Reprinted from Radio & Electronics Constructor.



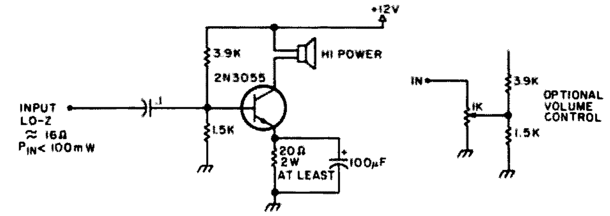
A grey scale generator for SSTV. Connect the output to the VCO of the camera. Gives 2300 Hz, 2100 Hz, 1900 Hz, 1700 Hz, and 1500 Hz. R1 is level adjust on the entire waveform. R2 sets the oscillator frequency to about 75 Hz. Thanks to Roger Peckham WA7SBH.



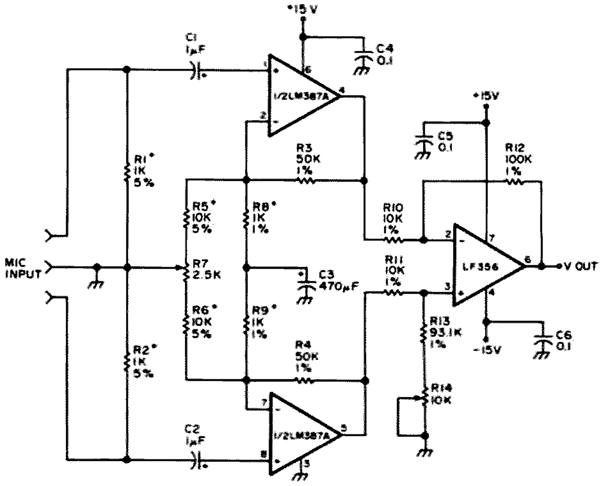


Touchtone pad circuit for finicky repeaters. R will be 100k to 4 megs, depending on the mike circuit. Select a value that doesn't distort mike audio but gives enough deviation from pad. C is .1 uF electrolytic. Use 10 uF for carbon mikes. Reprinted from SCRAMSGRAM.

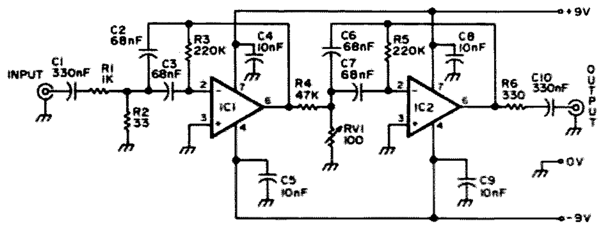
This very simple clock oscillator uses only three components. It's usable to 5 MHz and draws less than 10 mA. Four spare inverters are available for use elsewhere in the circuit. Thanks to Bruce Brown WB4YTU/WA9GVK.



This simple audio follower stage adds punch to low power radios and tape recorders. It will provide 5 to 7 Watts output with a 750 mW input. The optional volume control is for fixed volume sources. Be sure to use a hefty speaker, as most speakers will blow out. Thanks to Steve Uhrig WA3SWS.



This low noise balanced mike preamp uses the ability of op amps to amplify differential signals while rejecting common mode ones, thus eliminating the transformer and its inherent susceptibility to hum pickup. Reprinted from Audio Handbook, *National Semiconductor.*



An active CW filter that can use a variety of ICs, including the 741, 748, and 301A series. The first stage is fixed-tuned. The second can be set the same, or slightly offset to provide double humped bandpass. Reprinted from Radio ZS.

Novice Q&A

This column will be a monthly feature of 73 Magazine. It is hoped that it will be of assistance to beginners and old-timers alike. We only ask that your questions be kept as general as possible. We will try to answer all queries received. Please mail your questions to Technical Editor, 73 Magazine, Peterborough NH 03458.

Q. What is a simple solution to low vfo drive on 10 meters?

A. A vfo will not always work simply by unplugging a crystal and replacing it with a vfo. Here are some of the reasons for this. The output impedance of the vfo must be proper for the oscillator circuit used in the rig. You cannot drive a rig on 10 meters with an 80 or 160 meter vfo output, even though 7 MHz crystal for 10 meters is used. There must be enough rf output from the vfo for proper drive on 10 meters.

Most crystal oscillators have a high impedance input. If the vfo output is low impedance, there may be trouble. Changing from low- to high-Z requires another tuned circuit or redesigning the oscillator. Generally, if the vfo has low-Z output and the right oscillator a high-Z input, simply link-couple a resonant parallel-tuned circuit to the vfo, with the tuned circuit going to the oscillator.

Although it is possible to obtain 10 meter drive with 80 or 160 meter vfo output leads, it is easier to use a crystal frequency.

By adding a buffer-amplifier stage, increased drive may be obtained, although low rf output from a vfo is sometimes unavoidable. Increasing voltages to the vfo will not, in most cases, do a bit of good. Sometimes the impedance transformation will yield the additional rf voltage needed.

When using coax to couple the vfo to the rig, be sure it is the correct impedance. If a capacitor is used in series with the coax at the vfo end, disconnect it and try link coupling on the output coil to the rig. This will help if the input of the rig is low impedance.

Q. Is there a simple way of switching a pi-network for two-band operation?

A. This principle can be applied to any two adjacent bands; however, the circuit illustrates the constants for operation on 7 and 14 MHz bands. The effective inductance is 4 uH and the capacitance is 620 pF with the control switch, SW, set at the 7 MHz position. At 14 MHz the inductance and capacitance are reduced to 2 uH and 310 pF respectively.

Q. Is there a circuit diagram for a 1000 Hz af oscillator which can also double as a 100 kHz crystal calibrator? It must be transistorized and compatible for use with an SSB transceiver.

A. Suggest you use 5% resistors (½ W) if available, in the circuit. The output of the af oscillator can be switched into the "mike" position of the rig, as shown in the figure.

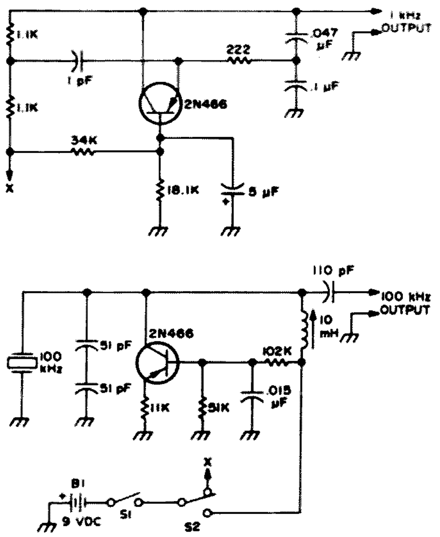
Q. What can cause backlash in a gear-driven tuning system, and how can it be corrected?

A. Anti-backlash gears in receivers sometimes become unwound or springs pop out of place due to shock in handling. To correct it, set the bandspread pointer at zero on the logging scale (have the bandspread capacitor fully meshed). In one model receiver, the white-metal gear should be set so that its long setscrew is 1/8 in. from the stop pin (this long setscrew serves as a stop on the other end of the tuning range). With the bandspread tuning mechanism in this position, loosen the setscrews and slide the white metal gear out of mesh. Wind the free brass gear one tooth and reengage the white metal gear. Other methods use a pair of spring-loaded gears whose wedge action takes up free play between meshing gear teeth.

To set the general coverage, the same procedure may be used; however, set the general coverage pointer at 100 on the logging scale. Final check of proper positioning of the dial vs tuning capacitor should be made on a known frequency like a local BC station.

Q. Any suggestions for checking erratic S-meter action in a receiver?

A. First check the S-meter tube. Then check each of the resistors in the circuit, especially the carbon controls. Clean them with an aerosol cleaner. Dirt and tarnish can be the cause of erratic action. Check the AVC switch contacts for proper contact, too – apply contact cleaner.



Q. When a beam is mounted on a high tower, how can you determine whether or not the transmission line (coax) becomes disconnected from the beam?

A. Simply check the final loading control. Also, use a grid dip meter. In most cases you will find that the antenna won't load as it did before. If a pi-network is used, you will find that the final loading control setting for a particular band will be way off – even for a partial load.

Q. What is a product detector?

A. Some receivers actually contain two detectors – a standard diode for AM reception plus a second circuit designed for CW and SSB reception. In such configurations, the second detector is referred to as a product detector – actually just another name for a converter-like circuit with a built-in bfo.

Many feel that the product detector exhibits limited or no improvement over the standard diode arrangement. Others – particularly the dyed-in-the-wool sidebanders – claim it provides significantly increased intelligibility characteristics.

Q. When operating, isn't a Q-multiplier supposed to act as a good, sharp crystal filter? Also, what causes squeal when its external controls are manipulated?

A. The majority of Q-multipliers installed in commercial ham receivers provide for internal adjustment. Usually, the adjusting control is set just below the threshold of oscillation. The Q-multiplier will not usually cause a "ringing" effect similar to that experienced when phasing a crystal filter.

For proper nulling or notching action, Q-multiplier controls must be carefully adjusted in vernier steps. A squeal indicates improper internal adjustment.

Q. How much difference is there in the velocity factor between coaxial and open-wire lines?

A. The velocity factor is a ratio of the actual wave velocity along a transmission line to the wave velocity in the air or free space. It varies from .65 to .85 with solid dielectric coax. Open-wire line's velocity factor is between .95 and .98.

Q. Can the 6146B be used to any advantage in a transmitter designed to use the 6146?

A. Yes, the 6146B is a direct replacement for the 6146, and – if power is available – the change is worthwhile. The 6146B is a better tube than the old 6146 and does give more rf power output.

Q. What circuit can be used to automatically ground an antenna when the main power switch is open?

A. See the figure. SW1 is a DPST switch which feeds 115 V ac to the

SSTV Test Generator

-- invaluable diagnostic tool

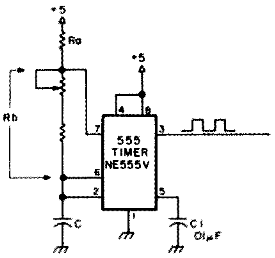
Probably the biggest obstacle facing amateurs building their own SSTV monitor is finding a stable slow scan signal source to properly adjust the monitor circuitry. This is especially true if the reader decides to design his own monitor or deviates from an existing design. The monitor itself generally cannot be used as a test unit because all the circuitry has to be adjusted and operating properly before anything can be viewed on the monitor's CRT.

This article describes an SSTV pattern generator which produces a continuous, high quality, 4x4 checkerboard SSTV signal which can be used with a triggered sweep oscilloscope to follow the slow scan signal through the monitor circuitry. The generator can be used to improve the design of an existing SSTV monitor or as a diagnostic tool to repair one.

The pattern generator described in this article is an adaptation of the circuit designed by Bert Kelley K4EEU.[1] NE555V timers are used as astable oscillators in place of the crystal oscillators, and the digital logic has been modified to produce a 4x4 checkerboard pattern.

After reading Bert Kelley's article on building a slow scan TV test generator, I didn't appreciate the need for such an instrument until seriously designing and building my own monitors; now I am convinced that anyone undertaking such an adventure should have a similar instrument.

The "front end" of my monitor at the present time contains circuitry from WB9LVI,[2] W6MXV[3] and myself. It is more or less the same route that WA9MFF took with his monitor,[4] a conglomerate of designs. Breadboarding the circuitry was relatively easy, but finding a stable signal source proved to be the biggest problem. I was able to use an audio oscillator to initially adjust the limiter, pulse counting discriminator, video amplifier, and sync separator, but fine tuning them for maximum performance was impossible using this method. A cassette recorder was used for a time, but was unsatisfactory from my standpoint as the video content was constantly changing, as was the video quality (I didn't have an opportunity to use a tape recorded by an SSTV manufacturer so I can't comment on them as an SSTV signal source). Remembering K4EEU's article, I resurrected it from my SSTV files, building the generator described in this article.



$$\text{frequency of oscillation} = \frac{1.44}{(Ra + 2\,Rb)\,C}$$

$$\text{duty cycle} = \frac{Rb}{Ra + Rb} \leqslant 50\%$$

Fig. 1. 555 timer connected as an astable oscillator. C1 is recommended by the manufacturer.

1200, 1500, and 2400 Hz Reference Oscillators

The primary attraction of the K4EEU generator is its inherent stability, accuracy, and lack of adjustments provided by three crystal controlled reference oscillators. I felt, however, that the stability of 555 timers was adequate for most SSTV alignment applications and designed my generator accordingly.

Several dozen Signetics NE555V timers manufactured over a two year period were tested over a temperature range of 25°C-55°C in an oil bath to determine their temperature coefficients (tempcos) and, therefore, their suitability as reference oscillators when operated in the astable mode. A test fixture was constructed so that only the NE555V was placed in the oil bath and not the external timing components. Fig. 1 shows a 555 timer connected as an astable oscillator. The tempcos of the NE555V timers measured .045% to .07% per degree centigrade (/°C). After the tempcos of the 555s were

determined, a number of different timing components were included in the oil bath to check the overall oscillator tempcos. Best performance was obtained using precision wirewound resistors and metallized polycarbonate film capacitors with oscillator tempcos measuring .05% to .08%/°C. The worst performance was obtained using carbon resistors and disc ceramic capacitors with oscillator tempcos exceeding .3%/°C.

As a compromise between performance and parts availability, I used RN55/60C (50 ppm) metal film resistors, cermet 15 turn trimpots, and metallized polyester capacitors. Using these components, oscillator tempcos did not exceed .1%/°C, which corresponds to 1.2 Hz/°C for the 1200 Hz sync oscillator, 1.5 Hz/°C for the 1500 Hz black oscillator, and 2.4 Hz/°C for the 2400 Hz white oscillator.

Circuit Description

Referring to the schematic, U1, U2, and U3 are 555 timers used as 2400 Hz, 1500 Hz, and 1200 Hz reference oscillators. The component values specified in the parts list have been selected so that the oscillator frequencies can be adjusted ±16-19% from nominal to allow for normal component variations. To improve the oscillator's ability to be set, R2, R5 and R8 can be changed to 2k and R4, R7, and R10 trimmed (selected) for the correct frequency. There is nothing critical about the values specified and they can be changed as required, but keep the duty cycle in the 47-49% range. Table 1 provides nominal values of Rb for preferred values of C when Ra equals 1k. Nominal values include 1/2 the value of the series trimpot selected. The outputs of U1, U2, and U3 are brought out to pins C, B, and A.

U4 is a TTL 7410 three input positive NAND gate. U4A and U4B alternately

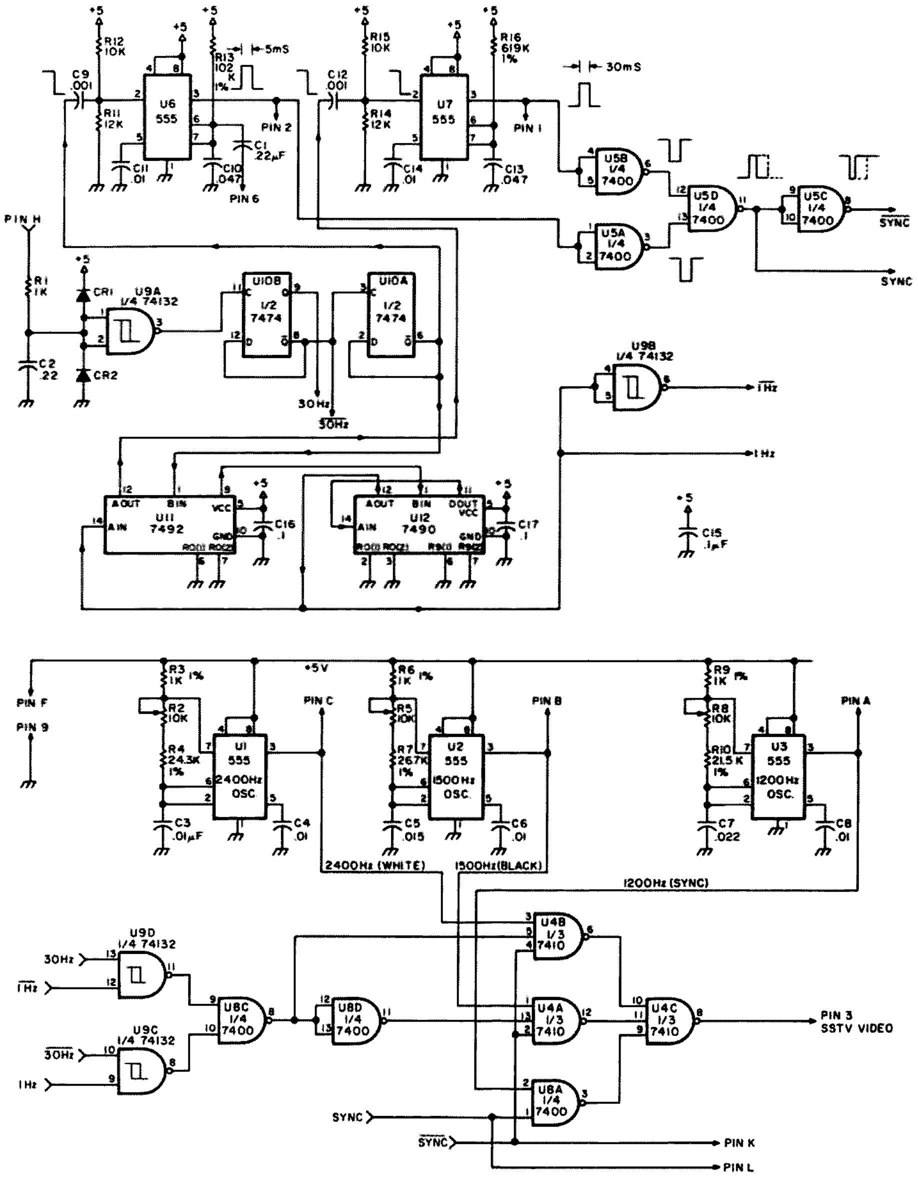


Fig 2. Schematic, SSTV pattern generator.

gate the 1500 Hz black and 2400 Hz white oscillators to the input of U4C, except when inhibited by the $\overline{\text{SYNC}}$ signal from U5C. During the time that U4A and U4B are inhibited by $\overline{\text{SYNC}}$, U8A is enabled by the SYNC signal from U5D, gating the 1200 Hz sync oscillator to the input of U4C. U4C is used as a three input inverter, its output, the SSTV video output, brought out to pin 3.

U5 is a TTL 7400 quadruple 2 input positive NAND gate used as a sync adder, combining the 5 ms horizontal and 30 ms vertical sync pulses from U6 and U7. The outputs from U5D and U5C (SYNC, $\overline{\text{SYNC}}$) are brought out on pins L and K.

U6 and U7 are 555 timers used as 30 ms vertical and 5 ms horizontal sync generators. U6 is triggered from the negative edge of U10A (15 Hz) and U7 is triggered from the negative edge of U11 (1/8 Hz). Pin 6 may be externally grounded to increase the horizontal sync pulse width from 5 ms to 30 ms. This provides a 30 ms wide sync pulse at a 15 Hz rate for easily adjusting the monitor's vertical sync separator. The outputs from U6 and U7 are brought out on pins 2 and 1.

U8 is a TTL 7400 quadruple 2 input positive NAND gate. U8C combines the output of U9C and U9D and, in conjunction with inverter U8D, alternately enables/disables gates U4A and U4B. U8B is not used.

U9 is a 74132 quadruple 2 input positive NAND Schmitt trigger. U9A squares the 60 Hz ac input pin H providing fast output rising/fall times, the positive edge triggering the first dual-D FF U10B. U9B is used as an inverter for the 1 Hz output of U12.

K	$\overline{\text{Sync}}$ (combined horizontal/vertical)
L	Sync (combined horizontal/vertical)

Table 2. Pattern generator pin assignments.

Opposite phases of the 30 Hz output from U10B and 1 Hz output from U12 are connected to U9C and U9D, which alternately gate the 1500 Hz and 2400 Hz oscillators every 30 picture lines and 16.67 ms producing a 4x4 checkboard pattern.

U10 is a TTL 7474 dual-D type positive edge triggered FF triggered by the positive edge of U9A. U10A and U10B divide the 60 Hz output from U9A by four, producing the 15 Hz SSTV horizontal scanning frequency. The negative edge of U10A triggers the 5 ms horizontal sync generator U6 and U11. Both phases of U10B (30 Hz, $\overline{30\text{ Hz}}$) are connected to the inputs of U9C and U9D.

U11 is a TTL 7492 divide by twelve counter and U12 is a TTL 7490 decade counter connected to divide the 15 Hz horizontal scanning frequency by 120, generating a 30 ms vertical sync pulse at the end of 120 lines or 8 seconds. Each counter contains a ÷2 element combined with a ÷5 element (7490) and a ÷6 element (7492). The schematic is not typical of two cascaded counters as they are cascaded as follows: 7492 – ÷6, 7490 – ÷5, 7490 – ÷2, and 7492 – ÷2. This connection provides the vertical scanning logic which produces the symmetrical 4x4 checkerboard pattern when combined with the horizontal logic in U9C and U9D. (In truth, the 4x4 checkerboard pattern is not symmetrical as displayed on a monitor, as 5 ms of the leading edge is blanked by the horizontal sync pulse; that is, the 1500 Hz and 2400 Hz oscillators are overridden by the 1200 Hz sync oscillators during the horizontal and vertical sync pulses.)

Construction: Printed Circuit Board

The components are mounted on a double-sided 5½" x 3" glass-epoxy circuit board fabricated to fit a standard 10 pin card edge connector with .156" spacing. I prefer not designing double-sided circuitry because of the problems encountered making them at home and the increased costs involved, but the artwork density using twelve ICs made it impossible for me to design single-sided circuitry which fit a 5½" x 3" circuit board. The artworks were prepared at home using commercially available artwork aids,[5] taped 2:1, and photographically reduced at a local photo shop. Using direct positive photoresist coated boards available from the Vector-Electronic Co. (CU70/45WE-2RN, 7 x 4½", 1/16" double-sided glass-epoxy), the boards were exposed, developed, and etched following the instructions that came with the boards. After cutting and drilling (#65 drill for IC pads, #60 drill for others), I tin plated the finished boards with Shipley LT-25 chemical plating solution.[6] After assembly, the component side is top soldered as required and jumpers soldered top and bottom in the three feed-through holes.

Adjustment

Obviously the easiest way to set the 1200 Hz, 1500 Hz, and 2400 Hz reference oscillators is with a frequency counter, and the values specified in the parts list should allow you to adjust the oscillators without re-selecting R4, R7, or R10. If a frequency counter is not available, the oscillators can be set with a triggered scope with a *calibrated* timebase. Set the timebase to .1 ms/div, internal trigger and adjust the 1200 Hz oscillator for a width of .83 ms, the 1500 Hz oscillator for a width of .67 ms, and the 2400 Hz oscillator for a width of .417 ms. Switch to line trigger and readjust the oscillators for a stable waveform (i.e., a waveform which is not slowly drifting from right to left or left to right across the screen). This adjusts the oscillators against the 20th harmonic (1200 Hz), 25th harmonic (1500 Hz), and 40th harmonic (2400 Hz) of the 60 Hz power line and is accurate within .1% provided your timebase is calibrated, as it is very easy to adjust the oscillators against the wrong harmonic.

Operation

The pattern generator requires +5 V ±.25 @ 150 mA and 6.3-12.6 Vrms ac, and the supply illustrated in Fig. 3 satisfies the power supply requirements for the generator.

Syncing the scope on the positive edge of the horizontal sync pulse will be adequate for most troubleshooting/design, and a few

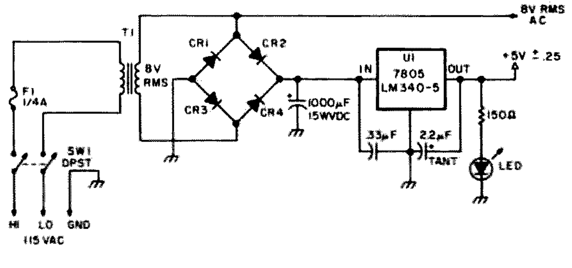

Fig. 3. This power supply satisfies the requirements for the pattern generator, but since the generator only requires 150 mA @ +5 V, it can easily be borrowed from an existing supply.

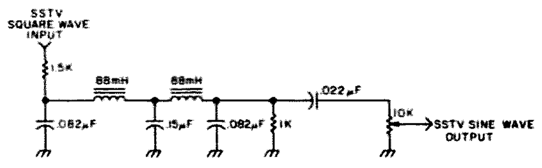

Fig. 4. This low pass audio filter used by K4EEU requires no power supplies.

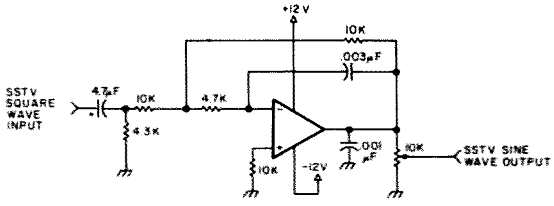

Fig. 5. WØLMD low pass audio filter.

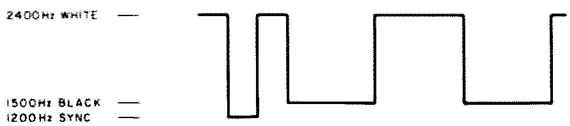

Fig. 6. Output of the WB9LVI low pass filter.

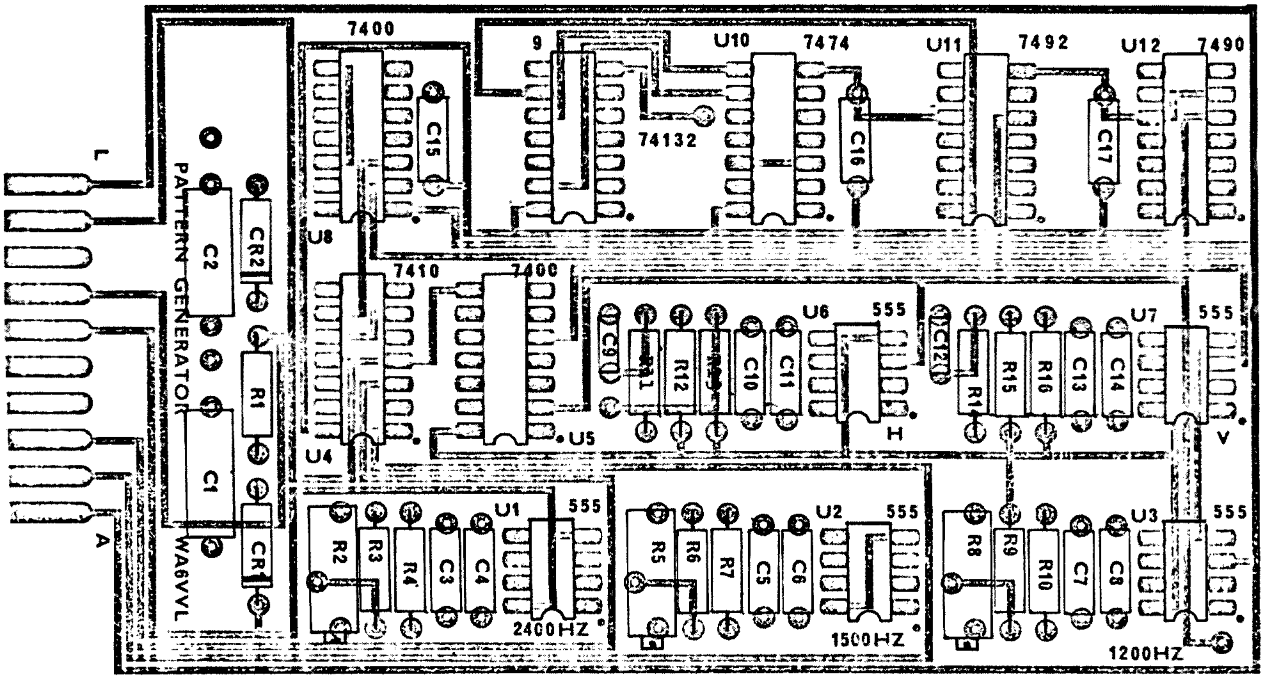
evenings spent with *73*'s *SSTV Handbook* should provide sufficient information to repair an ailing monitor with the generator. The 1200 Hz output can be used to tune the sync circuitry, and the 2400 Hz output can be used to adjust the discriminator. The horizontal and vertical sync pulses may be used as horizontal and vertical discharge pulses to drive the triggered deflection circuitry, and the checkerboard pattern can be used to optimize the gain(s) of the low pass filter for a square wave response with just enough overshoot (ringing) to enhance picture detail. The video output can be attenuated with a potentiometer to determine the minimum input for limiting, determined by limiter gain. Fig. 6 is the output of the WB9LVI low pass butterworth filter with the generator connected, and Fig. 7 illustrates the checkerboard pattern as displayed by the monitor.

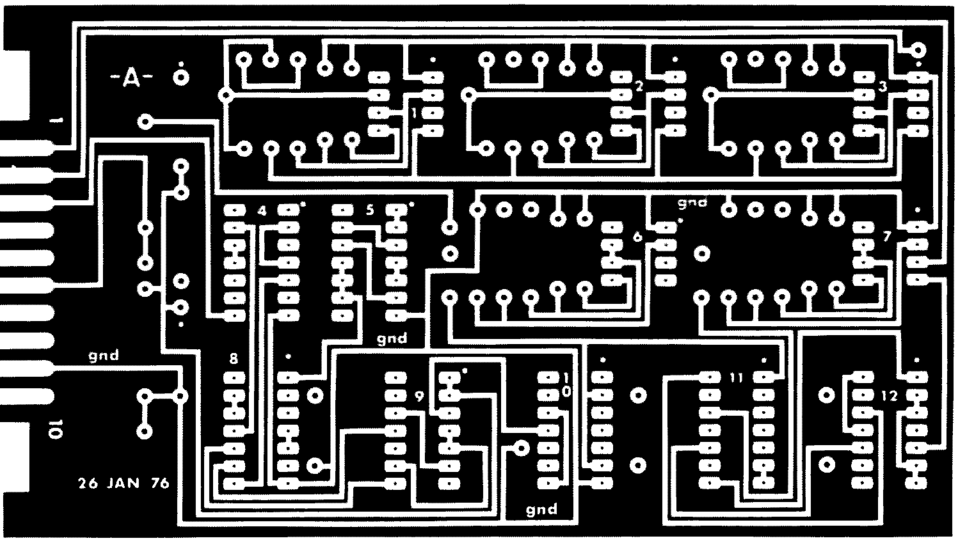
Although designed primarily for tuneup, calibration and repair, the generator can also be used for transmission by using the low pass audio filter used by K4EEU, shown in Fig. 4, to convert the square wave video to sine waves. I prefer this filter because it requires no power supplies, but an alternative is the filter used by WØLMD in several of his designs,[7,8] shown in Fig. 5.

Conclusion

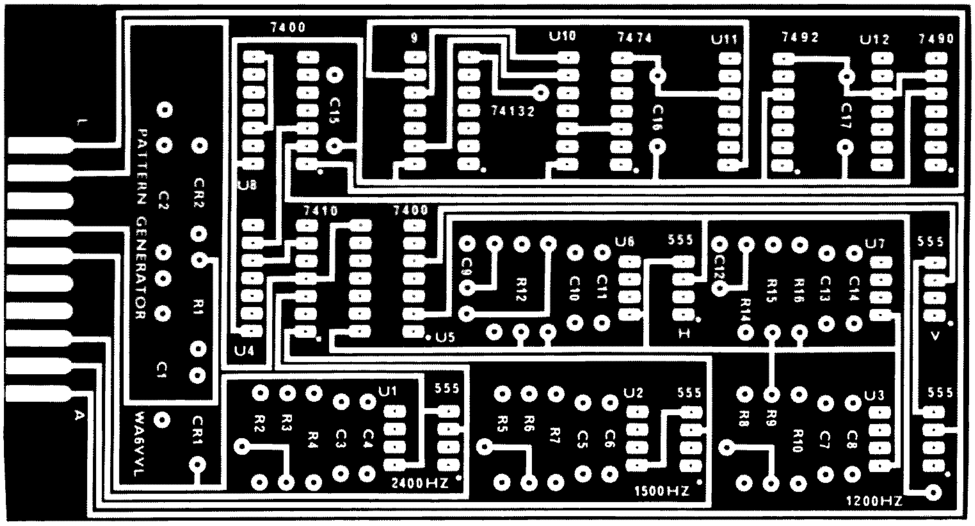
Compared to the cost of an SSTV monitor, the pattern generator represents a modest investment. Like K4EEU, once the completed generator was connected to my monitor, I wondered how I survived without it, and am now convinced that anyone who wants to roll their own monitor should have a similar unit. I'll be the first to admit



Component layout.



PC layouts.



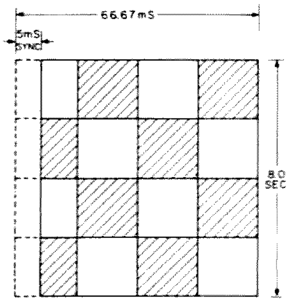


Fig. 7. Checkerboard pattern as displayed by the monitor. The pattern appears to be unsymmetrical because the leading edge is blanked by the 5 ms horizontal sync pulse.

that a monitor can be constructed and aligned without it, but it should save countless hours of work should a snag develop. ■

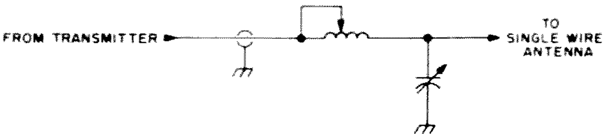
Novice Q&A



from page 21

power circuits, and SW2 is a SPST that does the antenna grounding.

Q. Using a trap antenna, erratic loading readings are obtained when it rains. What could be the cause of this?

A. The trap may be leaking. Also, there may be water entering the coax. With a good high-range ohmmeter (at the transmission line end), check the antenna — both when the weather is wet and when it is dry. A low reading when wet will indicate moisture is the problem. Disconnect and check the coax; then recheck the antenna itself with the coax disconnected.

Q. In an attempt to make a 10 meter transistorized converter work with a BC transistor radio, AM broadcast signals are received after the converter is connected to the BC set's antenna coil. Any suggestions?

A. If the antenna coil is not shielded, you will continue to pick up BC signals. Shield the coil and connect it via a coaxial cable to the output of your converter by placing a .0022 uF capacitor in series with the cable's center lead. Ground the coax shield to the BC set chassis.

Q. How can a long wire antenna be matched to a transceiver without an elaborate or heavy antenna tuner, when used away from home?

A. Any single wire antenna can be matched to the low impedance of your transceiver with the circuit shown. A surplus coil and a capacitor of 200-365 pF may be used. Using an swr meter, adjust the rotatable coil and capacitor for proper matching and maximum transmitter output. This circuit may also be used for mobile operation.

How Does Your Rig Perform?

- - an example using the HW-7

Alfred F. Stahler W6AGX
5521 Big Oak Drive
San Jose CA 95129

Some time ago I spent two weeks in Hawaii, enjoying the sun, surf and QRP operation/KH6 using the Heathkit Model HW-7 transceiver. I used two "twin lead" folded dipoles about 15 feet high and batteries for power which were recharged during the day using solar energy. The performance on twenty and forty meters was excellent: ZL1, JA∅, JA1, LA1, UA∅, KL7, VE5-6-7, W4-5-6-8-9-∅ – all with good (S3-S8) signal reports. My log shows that nearly 50% of the stations called replied.

After returning to the mainland, I wondered about the truth of "2 Watts" and decided to measure the performance characteristics of the HW-7 transmitter. The object of this article is to present the experimental test data that I obtained with my HW-7 so that other amateurs will have more knowledge about their HW-7 and how to use it for optimum performance.

Fig. 1 shows the measured input current as a function of the applied voltage. This data was taken with the transmitter adjusted for maximum power out on twenty meters. The results are linear over the voltage range from 8-16 V. Below 8 V the unit does not always oscillate and the output waveform is very distorted.

Fig. 2 shows the measured power output of the transmitter as a function of supply voltage for the three operating bands. The frequencies used were 7.05 MHz, 14.10 MHz and 21.15 MHz. The

power was determined from the measurement of the peak-to-peak voltage across a 50 Ohm, non-inductive load.

$$P = \frac{(E_{pp} \times 0.50 \times 0.707)^2}{R}$$

The peak-to-peak output voltage was measured with a Textronics Model 546 oscilloscope.

Fig. 2 shows that the power outputs on 40 meters and 15 meters are essentially the same, while the 20 meter output is considerably higher. The Heathkit manual claims that the power input varies from 3 to 2 W with increasing frequency, implying a corresponding decrease in power output. I cannot explain this apparent discrepancy between the test and published data.

As with the power input, the power output increases linearly with supply voltage. For battery operation, this characteristic is fortunate because it results in a gradual, rather than sudden, drop in output power as the battery discharges. However, the need for well charged batteries is apparent: A 2 V drop from 12 to 10 V reduces the power output by 50%.

With the power input and power output established, the next question concerned the optimum load for the transmitter. The specifications prescribe a 50 Ohm, unbalanced load. To measure the effect of load resistance on power output, a series of non-inductive, resistive loads was applied to the transmitter and the power output was measured. Fig. 3 shows the results of these measurements.

From this data it appears that the transmitter is optimally matched to a 62 Ohm load, but the difference between 62 and 50 Ohms is negligible. This data was taken on 20 meters with a 12 V supply.

In actual practice, antenna loads seen by a transmitter are seldom resistive, and usually show either inductive or capacitive reactance as well as resistance. To measure the effects of reactance on power output, various inductive and capacitive elements were placed in series with a 50 Ohm, non-inductive, resistive load. The power output was measured across the resistor.

Fig. 4 shows the power output as a function of the reactance of the load for the three bands. The power output is essentially constant for up to 10 Ohms of either capacitive or inductive reactance and drops rapidly with increasing reactance.

The range of reactance variation is limited by the variable capacitor. Since the impedance seen by a transmitter can vary over a wide range of values with antenna design, and transmission can vary over a wide range of values with antenna design and transmission line length, one should be very careful to provide the transmitter with a resistive load. With increasing reactance the "relative power" meter reads higher and higher, even off scale. The peak reading still corresponds to the peak power output, but the relative reading is valid only for non-inductive, resistive loads.

The HW-7 has a reputation for creating TVI, and mine is no exception. As far as I know, the interference is limited to TV sets in close proximity to the transmitter, but considering the DX achieved with less than 3 W, the interference range might

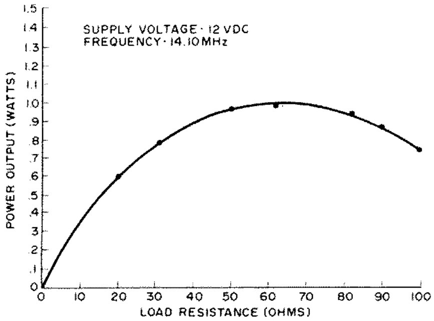

Fig. 3. Power output vs. load resistance.

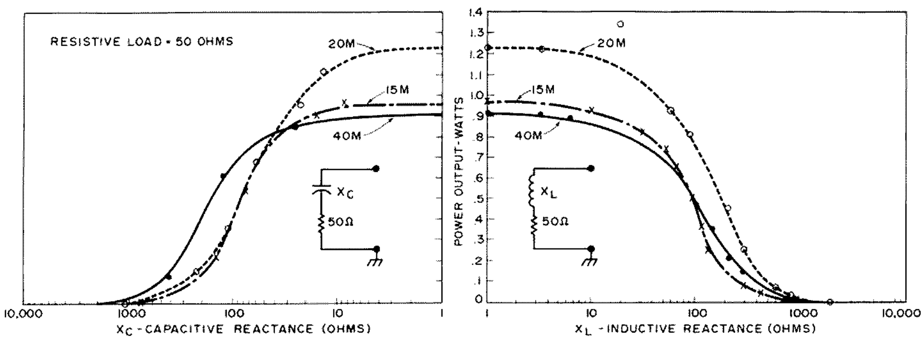

Fig. 4. Power output vs. inductive and capacitive reactance.

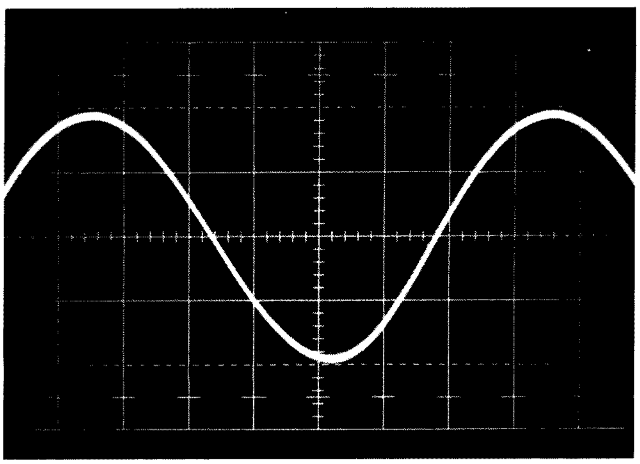

Fig. 5. Output waveform, 7.1 MHz.

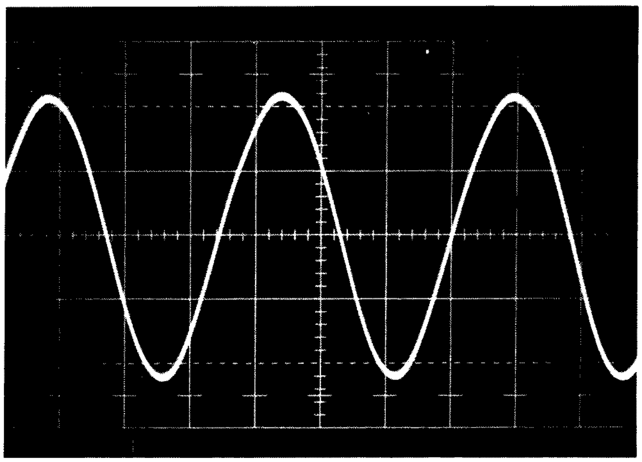

Fig. 6. Output waveform, 14.1 MHz.

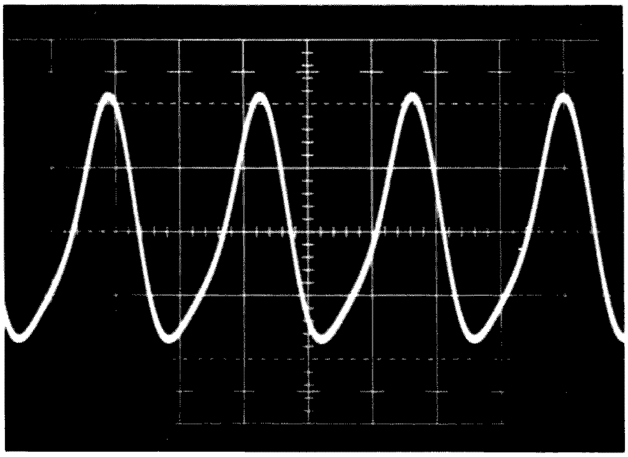

Fig. 7. Output waveform, 21.1 MHz.

be quite large.

The output waveforms of the transmitter were measured, using the 546 oscilloscope. This data is shown in Figs. 5, 6 and 7. Each of these photos shows the output waveform measured at peak power. For all three bands, this waveform is sinusoidal with little or no harmonic content. Figs. 9, 10, and 11 show the power output at the same frequencies

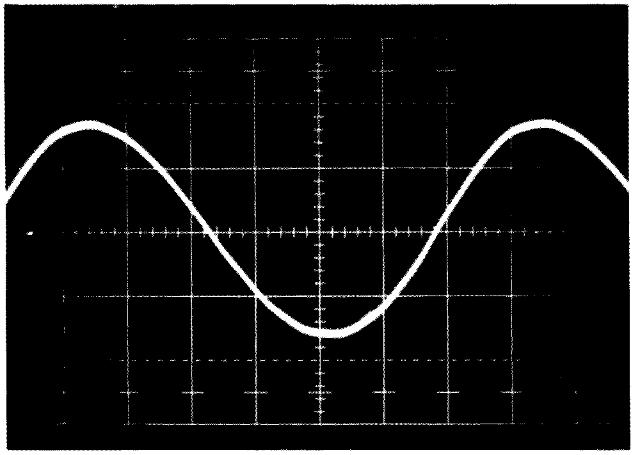

Fig. 9. 7.1 MHz de-tuned.

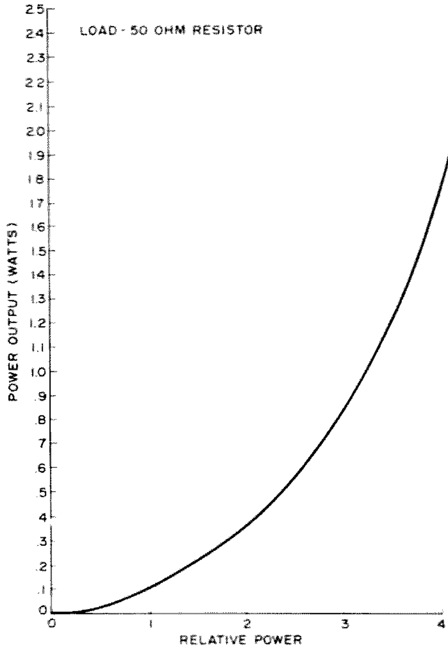

Fig. 8. Calibration curve, power output vs. relative power.

but with the leading capacitor turned slightly off peak relative power indication. Here the harmonic content becomes high, particularly on 15 and 20 meters, although the power output is not markedly decreased. This effect of de-tuning on harmonic content is more pronounced when de-tuned on the high frequency side of the relative power peak.

Fig. 8 shows a calibration curve of the relative power meter to yield absolute power output as a function of meter reading. This curve, however, is only valid for the 50 Ohm resistive load supplied with the kit.

The measured and on-the-air performance of the HW-7 transmitter shows that it is fine for QRP operation. The only possible problem areas are matching of the unit to a non-resistive load with the resultant misleading relative power indication, and that careful power peaking is required to minimize TVI. ■

Art and the PC Board

-- new uses for copperclad boards

Traditionally, printed circuits have been an aid in the mass production of electronic devices such as radios, TVs, telephones, etc. However, there is no reason to restrict the use of PC materials to traditional applications.

As the photographs show, they may be used for front panels, decorative plaques, and name tags. The more intricate patterns are most conveniently done by means of a photographic process, one that may be done at home. Fig. 4 and the top of Fig. 3 are two examples of this.

The wall plaques and transmitter front panel require a minimum of materials. Double-sided board is easier to get than single-sided for many reasons. It is also the best for this use as the back side will readily take solder.

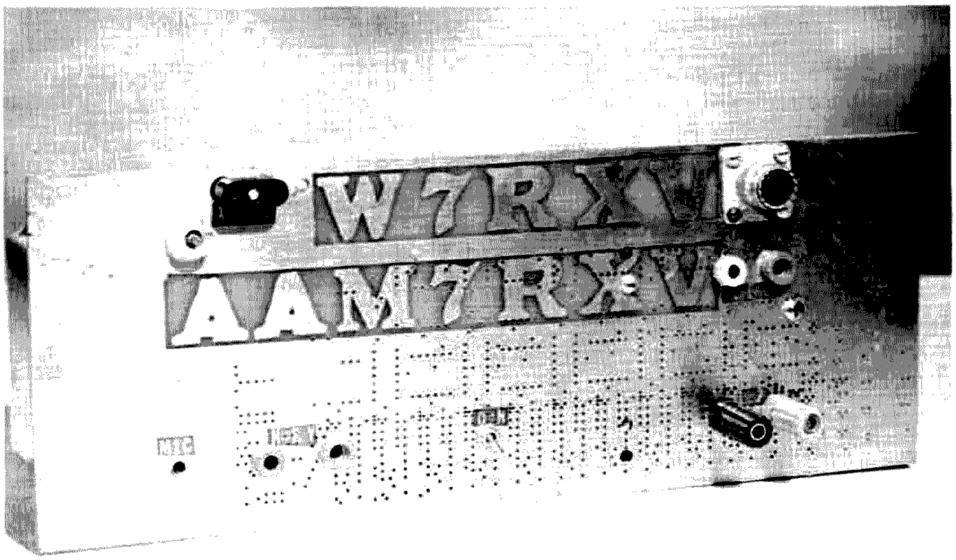

Fig. 1. ¾" letters.

Etch resist or laundry marking pens and paper masking tape are used to keep the etching solution where it belongs. The laundry markers are available for about 1/2 to 1/3 the price of the etch resist pens. (Sanford's "Rub-A-Dub" proved to be insoluble in water and ferric chloride.)

The dry transfer or press-on type of decals also work quite nicely as may be seen in Figs. 1 and 5. (Figs. 3, 4, 5 are essentially life-size.)

The results shown in the lower portion of Fig. 3 are what gave rise to the use of stencils for the plaques. I never did get along too well with a triangle and tee square.

If you have been paying attention, then by now you should have on hand the following items: triangle, tee square, ferric chloride, laundry markers, masking tape, copperclad, steel wool, stencils, and a tall pitcher of lemonade.

So as to preclude two trips to the store, the photo chemicals may be picked up too. Kodak's KPR system has proved to be quite reliable. The information that came with it seemed to be lacking in detail. More about that method later.

As anyone who has worked with printed boards can tell you, cleanliness is next to impossible, but absolutely essential.

The side of the board with the smallest number of nicks and scratches should be scrubbed with steel wool. After it glistens, apply several drops of rubbing alcohol and wipe dry with a paper towel. Surprise, surprise, you thought the board *was* clean!

Lay the board face down on a clean paper towel and apply a nice smooth bubble free coating of masking tape to the back side. If the board is wider than the tape, then overlap the edge of the tape.

Make sure the tape is securely down against the board.

If a combination of decals and stenciled letters is going to be applied, the stencil should be used first. Take your time and fill in the stencil with plenty of ink. Any slop-over may be corrected with a razor blade or better yet, an X-acto type of blade. A large error may be cleaned up with rubbing alcohol.

Follow the manufacturer's ideas with the decals. Try to avoid rubbing the center area of closed letters. The gum that is transferred in the process may act as a resist. If that does happen it may be corrected during the etching by carefully scratching the area with a thin pointed instrument. The board should be rinsed off with cool water before trying this correction.

The borders are made by applying masking tape. Where they overlap at the corners, put down a good layer of ink first.

A little freehand artwork is used to fill in the letters and avoid the broken appearance normally associated with stencils.

The photographic process is somewhat more involved, and somewhat more expensive. If a large number of the same thing is going to be made, then the higher cost might be warranted. Club projects that require a lot of boards would be one example. There would almost certainly be enough materials left over for the processing of a few call letter tie clips, etc. Fig. 4 is an example of this. The upper part of Fig. 3 shows what can be done to dress up the drab looking company-issue type of formica name tag. Two alligator clips are soldered on the back.

The boards are cleaned as above and handled with rubber gloves. Fingerprints and similar contamination must be avoided. The boards are coated with the etch resist by means of a medicine dropper. (This is done under yellow "bug" lighting.) Apply an excess of solution and flow it around the surface by tilting the board. The board is held vertically and the extra solution is drained off. Don't keep them vertical too long.

Place the boards in a preheated oven for 10 to 15 minutes. Oven temperature is 150-180° F. Remember, the boards are sensitive to light before they come out. Although this pre-bake may be skipped, it gets dry boards ready for exposure in about 20 minutes, instead of 24 hours. Your pattern is more likely to stay with you during high temperature processing, too.

Exposure time was 8 minutes at 24 inches with a BEP lamp. This is a 300 Watt photoflood. First-hand information of sunlight exposure time is not available due to the fact that there wasn't any sunlight available between the hours of midnight and 6 am when these items were made. Daylight exposure time should be about 2 minutes though.

The exposed board is dropped face up into the developer for 60 seconds. An aluminum cake pan with a

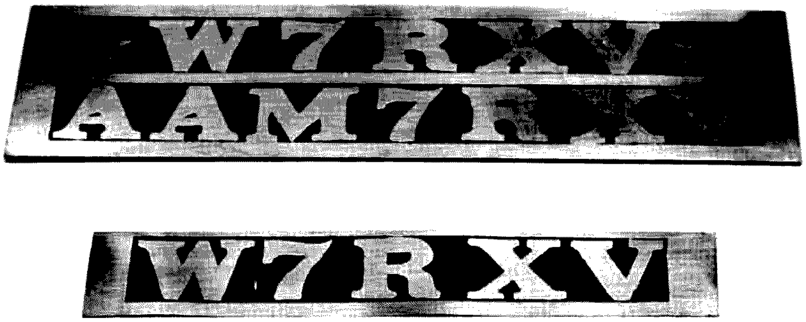

Fig. 2. 1" letters.

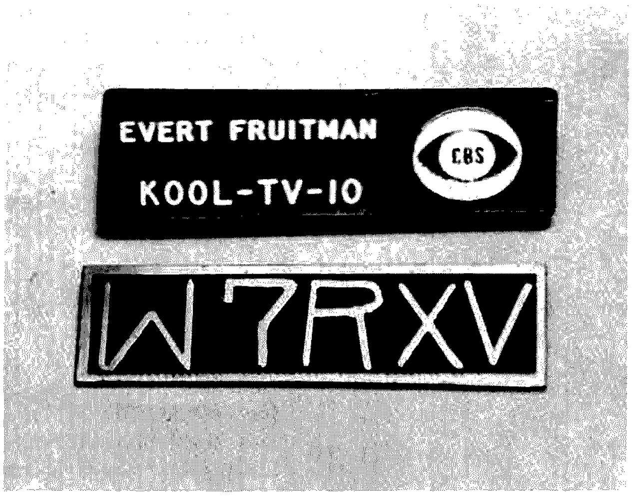

Fig. 3. Just about actual size name and call tags.

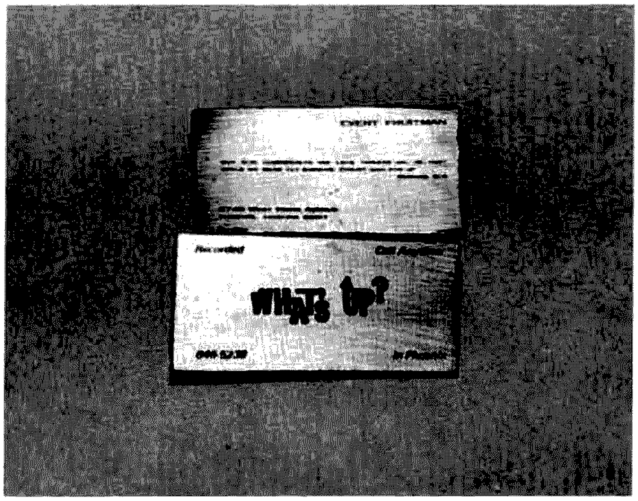

Fig. 4. Note fine resolution of photo process.

Fig. 5. Almost actual size.

sliding cover helps keep the odor to a relatively low level. Gently agitate the solution during the development. Immediately after developing, the board is given a cool running water rinse. A gentle stream of water should be directed at the surface for several seconds. A faint pattern may be visible as it dries.

The boards may be etched at this time, but it is better if they get a post bake for about 10 minutes at 180° F. This may be done in normal room lighting.

The developer may be reused. Several ounces of developer may be poured into a small can with a tight fitting lid and used until it starts looking a bit dirty. Not the most scientific method for determining the end point, but quite practical.

The smallest available quantity of resist is a quart. That will do many boards. The developer comes in gallon cans. Generally speaking, the photo stores can tell you who handles the KPR series of chemicals or can order them for you.

There are some canned spray photoresists at some of the radio stores. We tried some of the canned variety but they didn't seem to work too well. Either they had been sitting on the store shelf too long (and in the Arizona heat that may not take too long either), or the chemistry needed to be worked out better.

After the boards have been etched and dried, they may be cleaned with steel wool. There are spray lacquers that make a nice durable coat. For best results, give them a 10 minute bake at about 180° F. A coating of the YF's clear fingernail polish does wonders for the smaller items such as the name tags, tie clips, etc. The tape is removed from the back and alligator clips, safety pins, etc., may be soldered in place.

It might be in order to give some details about the etching process. There are many fine comprehensive articles on the subject, but this isn't going to be one of them.

Everyone seems to have his own favorite method and etchant. We like ferric chloride. It is readily available and almost harmless. It does stain hands and clothing, the latter on a permanent basis. Wear old clothes and rubber gloves. Drug stores have some types for as little as 50¢ a pair. They also carry the stencils.

The etching may be done in plastic or glass containers. DO NOT let the ferric chloride come in contact with aluminum!

One of the popular methods uses heatproof glassware, and the solution is kept heated during etching. Infrared lamps aimed from above, or a very gentle fire underneath, is one way it is done. The dish is slowly rocked during the process. The board is face up.

We took some old plastic bleach bottles and cut the top off just about in line with the center of the handle. The solution is poured into the bottle and this is placed in a pan of hot water. The heat may be left on during the process. If the boards are too long to go all the way into the solution, then use enough solution to cover at least half of the board. It is lifted up and down or used to stir the brew until etching is done. If the board is a long one, then turn it over and finish it off. This was done with the transmitter front panel and plaques shown in Figs. 1 and 2. The 1 and 2 quart size bottles are the most convenient to use for this. The boards may be rinsed off with water and examined anytime during the etching process.

The top of the bottle makes a nice funnel for pouring the used etchant back into its container when the job is completed.

It takes about 5-10 minutes with fresh warm etchant to etch the average board. If it isn't convenient to agitate the thing while it's etching, it will take quite a bit longer to finish cutting it. But it will cut.

If you don't feel like adding some fancy decorations to the shack, Fig. 6 shows that copperclad may be used as an easily machined and inexpensive and decorative material. ■

The "New" 88 Channel IC-22

- - add two switches and flip

By now, I'm sure you have heard at least three tales of how to get more frequencies out of your Icom IC-22S. Well, hang on! Here comes one I think you will like.

Icom supplies a chart for programming the diode matrix of the 22S. It was from this chart I discovered you can get at least 88 channels by simply adding two small switches and programming it in a logical manner. The modification should cover over 95% of the repeaters in the United States as well as

FREQUENCY VS. DIODE PLACEMENT

		Frequency	Total "N"	D-7	D-6	D-5	D-4	D-3	D-2	+30 kHz B D-1	+15 kHz A D-0

14 standard simplex frequencies.

You start out by programming the radio for the 22 "base" frequencies. Icom pre-programs the first five channels; these must be reprogrammed.

You then add two small switches to the radio, to add +15 kHz, +30 kHz or both, for +45 kHz, to the base frequencies. I marked these switches "A" and "B", so (for example) channel 5AB (both A & B on) would be 146.25/85 +45 kHz, or 146.295/895. The switches can be installed almost anywhere on the radio. I added mine to the upper cover.

The common of both switches is wired to +9 volts from the matrix board. Switch "A" (+15 kHz) is wired in series with a diode (1N4148) to any hole in the top column of the matrix board marked 1 (DØ), opposite the channel numbers at the bottom of the board. These holes at the top of the board are all common to one another on the back side of the board.

The second switch (+30 kHz) is wired to any hole in the second row from the top. The diodes in both cases are inserted with the banded end through the board, and then soldered to the back side of the board. Next, solder the wires from the switches to the tops of the diodes and you're ready to go!

This modification does produce one interesting operating characteristic. If either switch "A" or "B" is on, and you pass an unprogrammed channel, the Icom 22S will "lock" onto this blank channel until released by momentarily switching off power.

Just think, you've quadrupled the capacity of your 22S for the cost of two switches! Not bad at all.■

Chan. #	(base) program radio for	A & B off	base +15 kHz A on	base +30 kHz B on	base +45 kHz A & B on

The listed data tells you the time and place OSCAR crosses the equator in an ascending orbit for the first time each day. To calculate successive orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the first crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world, it will descend over you. To find the equatorial descending longitude, subtract 166 degrees from the ascending longitude. To find the time it passes the north pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR when it is within 45 degrees of you. The easiest way to do this is to take a globe and draw a circle with a radius of 2480 miles (4000 kilometers) from the home QTH. If it passes right overhead, you should be able to hear it for about 24 minutes total. OSCAR will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15 degrees from you, add another minute; at 30 degrees, three minutes; at 45 degrees, ten minutes.

OSCAR 6: Input 145.85-145.95 MHz; Output 145.90-146.00 MHz; Output 29.45-29.55 MHz; Telemetry beacon at 29.45 MHz. OSCAR 7 Mode A: Input 145.85-145.95 MHz; Output 29.40-29.50 MHz. Mode B: Input 432.125-432.175 MHz; Output 145.925-145.975 MHz.

OSCAR 7 is turned off every Wednesday to conserve power. All mode B orbits that fall on GMT Mondays are designated QRP. A limit of ten Watts ERP is recommended, with a 100 Watt limit at all other times. Higher power will drain the OSCAR batteries at an accelerated rate.

AMSAT

During the months of January and February 1977, a number of normally OFF Wednesday orbits of AMSAT-OSCAR 6 will be turned ON for a special QRP Test. The 2 to 10 meter transponder of AO-6 will be turned on for as many ascending and descending node passes as possible on the following dates: January 5, January 19, February 2 and February 16, 1977. Stations participating in this QRP Test should run no more than *TEN WATTS Effective Radiated Power* and should indicate so during their transmissions. All other stations are asked not to transmit in the AO-6 uplink passband of 145.900 to 146.000 MHz during the test. The Wednesdays chosen for the tests fall on odd days of the year which also happen to be Mode-AX days for the AMSAT-OSCAR 7 satellite. Since the orbits of the AO-6 and AO-7 begin to overlap in January and February, it has been decided that AO-7 be switched to Mode-BX for these tests in order to avoid confusion which might result if both satellites' 2 to 10 transponders were on at the same time. The 70 cm to 2 meter transponder of AO-7 should *NOT* be used during Wednesday AO-6 QRP Tests or any other Wednesday unless so scheduled by AMSAT.

All orbits of all AMSAT-OSCAR 7 Mode-B Mondays from now until further notice will be on for QRP purposes only. Stations using the 70 cm to 2 meter transponder on these days should run no more than *10 WATTS ERP*. All Mode-B users are strongly urged to use as far below the maximum recommended 100 Watts ERP as possible to help to keep the AO-7 battery voltage above the point at which the low voltage sensors switch the transponder into Mode-D, the battery recharge mode.

LAUNCH DATE FOR PHASE III SATELLITE ANNOUNCED

AMSAT has been notified by the European Space Agency (ESA) that the Phase III satellite will be accepted as a secondary payload on test flight number 2 scheduled for launch in December, 1979. The Phase III satellite, now under development by AMSAT, will contain an onboard microprocessor that will allow the satellite to control itself. The highly elliptical orbit chosen will allow amateurs to have dependable satellite communications for up to eleven hours at a time.

Funding for the Phase III spacecraft is especially critical, as AMSAT will have to purchase and assemble the one square meter of solar cells, $30,000. The funding required for Phase III will probably be $150,000.

To meet these needs, a number of fund-raising projects will be initiated. For instance, it has been suggested that we ask AMSAT members to sponsor a solar cell in the satellite.

We have noticed an increase in memberships and donations when satellite articles appear in the major magazines. Thus, one of the fund-raising projects will be to run a dozen satellite articles as a group in *73*, coinciding with the launch of A-O-D.

This was done in July, 1975, and we found the effort to be worthwhile. Several pages of pictures, text and a membership/donation form will be made available by the magazine for AMSAT to publicize the Phase III project.

To be successful, we will need articles on many subjects: DX, antennas, awards, telemetry analysis, beginners' articles, A-O-D, microprocessor applications and operating aids. Joe Kasser G3ZCZ/W3 and I are willing to provide pictures, typing and editorial support if necessary. For simplicity, we ask that the articles be submitted as a package by me around February 28, 1977. Authors will be paid directly from *73 Magazine*. In addition, some of the articles will be published in the AMSAT Newsletter.

So that I will know how the project is going and what subjects Joe and I will need to add, I would appreciate a QSL card stating your willingness to help and your subject area.

Ellicott City MD 21043

FCC

In an Order released October 13, 1976, the Commission announced it had amended Section 2.302 of its Rules effective November 2, 1976 to permit the issuance, subject to availability, of specific 1 x 2 callsigns in the Amateur Radio Service (that is, callsigns consisting of one letter, one digit, and two letters) with suffixes beginning with the letter "X" to eligible applicants holding amateur Extra class operator licenses. In its Order, the Commission stated that, pursuant to its First Report and Order in Docket 20092, 58 FCC 2d 1272 (1976), it wished to make as many 1 x 2 callsigns as possible available to amateur Extra class licensees.

The Commission has now determined that 1 x 2 callsigns prefixed with the letter "N" will be available to eligible amateur Extra class applicants beginning November 2, 1976. Callsigns beginning with the letter "N" are presently allocated to the Amateur Radio Service, and this action does not, therefore, require a rule amendment. Eligible amateur Extra class applicants wishing to obtain specific 1 x 2 callsigns prefixed by the letter "N" may apply under the provisions of Section 97.51 of the Commission's Rules on or after November 2, 1976. Amateur Extra class licensees first licensed as amateurs twenty-five or more years ago and amateur Extra class licensees who obtained their amateur Extra class licenses on or prior to November 22, 1967 could apply for specific 1 x 2 callsigns on November 2, 1976. Extra class licensees who obtained their amateur Extra class licenses on or before July 2, 1974 may apply for specific 1 x 2 callsigns on January 1, 1977, and amateur Extra class licensees who obtained their amateur Extra class licenses on or before July 1, 1976 may apply for specific 1 x 2 callsigns on April 1, 1977. All amateur Extra class licensees are eligible to apply for available 1 x 2 callsigns on July 1, 1977.

Holbrook MA 02343

Here is a gadget that should appeal to the two meter FM fraternity. Living near metropolitan Boston where there are 7 autopatch repeaters, one gets many opportunities to call the police and fire departments both for oneself and to assist other amateurs.

Several months ago, while still a newcomer to two meters, I heard a phone number being dialed very rapidly. I waited until the patch was finished then asked the other amateur what he had used. It turned out to be a card dialer. I thought, "Why couldn't this be done electronically?" A card dialer is a mechanical kluge, big, bulky and requiring shuffling through cards which may be easily mutilated or lost. This autodialer may be used in motion after a little practice with binary coded decimal numbers.

Theory of Operation

The heart of this autodialer is two 256 x 4 read only memories which are addressed in parallel. A binary coded decimal address of 0 through 15 is selected by switches marked 8, 4, 2, 1. For example, if you wished to dial phone number seven in your list of numbers you would set switches 4, 2 and 1 in the up position, just a simple matter of addition. 0 is all switches down and 15 is all switches up; 8 plus 4 plus 2 plus 1 is equal to 15. 0 through 15 equals 16 addresses. After your number is set, the start switch is pressed setting pin 3 of the RS flop U1 low, which resets the binary counter U2 to the count of zero, thereby permitting U1 pin 11 to go high starting the clock U5. When the start switch is released, the next rising edge of the clock will produce a binary count of one on U2 and, at the same time, a low to enable the read only memories is produced at U1 pin 8. The binary counter is allowed to count to eight; on the rising edge of the nine

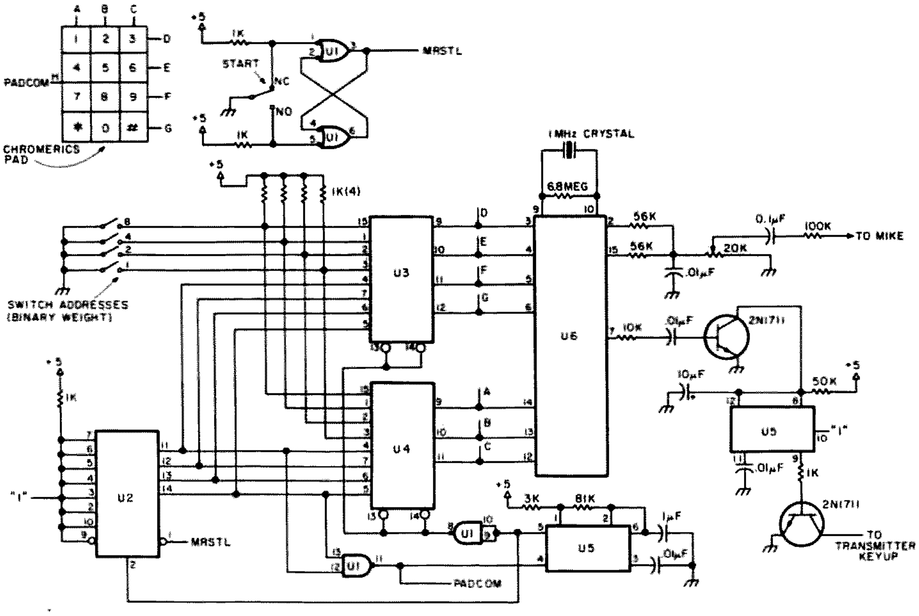

Fig. 1. U1 – 7400; U2 – 74161; U3, U4 – 256 x 4 ROM; U5 – NE556; U6 – MC14410P.

count, pins 12 and 13 of U1 will both be high, giving a low on U1 pin 11, shutting down the clock which will remain stopped until the next time the start button is depressed.

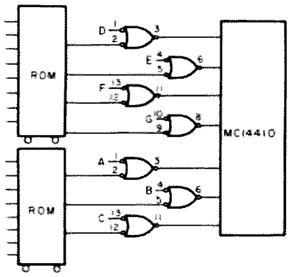
Supposing we assume that you have selected the seventh phone number appearing on your list; the address of the ROMs before accessing the start button would be 01110000. On the first count after starting, it becomes 01110001, then 01110010 for the second count, 01110011 for the third and so on.

The MC14410 takes active lows in a 2 out of 7 code. For example, the digit 1 is a low on pins 3 and 14. See Table 1.

Let's take a phone number and see how we can program the ROMs. Assuming that the first phone number which will be address 0 is 963-1234, we can write a truth table as in Table 2.

Since the binary counter always starts at zero, we don't want anything on the

Fig. 2. Necessary if TTL output ROMs are used. Added gates are 7408 ICs (2 required).



ROM outputs; also, if your phone number is a seven digit number, the same thing will be true on the count of 8. This autodialer will take either 7 or 8 digit phone numbers.

When the clock is stopped by virtue of a low being on U1 pin 11, this output can be used to enable the TT pad for repeater access or for phone numbers that don't appear in memory. It is not recommended that access numbers be stored in memory unless your favorite autopatch repeater uses Ma Bell cup-core tone decoders, as the clock is running at ten cycles per second, i.e., a seven digit phone number takes only 0.7 seconds to complete. The phase locked loop decoders that most repeaters use are not fast enough to respond to this speed. Once you have brought up the patch and are talking to Ma Bell's lines, you are only limited to the phone company decoders which will accept pulses of 40 milliseconds on time and 60 milliseconds off time, so if you wished, the speed of this autodialer could be increased a smidge.

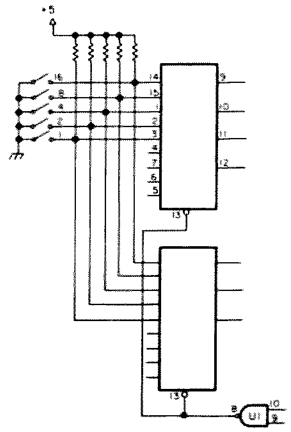
The MC14410 has a high going signal at pin 7 every time a number is selected. This is used to fire ½ of a 556 in a one shot configuration to turn on your rig, thus making it unnecessary to key your mike button when using the autodialer.

The 0.1 uF capacitor in series with the 100k resistor coming off of the wiper arm of the pot will interface with high impedance input rigs such as the Regency HR2B. Other types with low input impedances or rigs that use a lot of audio processing, such as the Icom IC-230, may require selection of other values.

The South Shore Repeater Association of Scituate, Mass. is offering this autodialer in a partial kit form consisting of an epoxy PC board and two ROMs pre-programmed to 16 phone numbers of your choosing. For further information, drop me an SASE.

For those of you who wish to roll your own, a few words of caution. The ROMs must satisfy the following conditions: (1) be enabled by a low on the chip select; (2) when disabled, all outputs must go high; (3) have tri-state or open collector outputs; (4) if open, collector outputs must be pulled up by 1k resistors. A good bet would be the Signetics 82S129 being sold by S. D. Sales Co., Dallas, Texas, for $2.95. I used the Harris HPROM-1024. TTL ROMs could be used but then you would have to OR the ROM outputs and the TT keyboard (see Fig. 2).

Fig. 3. 32 phone number version. Good choice for 512 x 4 ROM is MM16306.



A 32 phone number dialer may be built using 512 x 4 ROMs. This requires the addition of one more switch and one more pull-up resistor which would have a number weight of 16 (see Fig. 3). ■

What's the Best Antenna for 160?

-- the inverted vee compromise

The downfall of potential 160 meter operators is most usually the antenna system. For some unexplainable reason, many persons who would operate the 1.8 MHz band apparently believe, perhaps due to the frequency, that any antenna made to load will produce satisfactory results. Satisfactory results are different to different folks, but if 160 is to be enjoyed to its potential, haphazard antennas are not the medium.

It is not the intent of this article to debate 1.8 MHz antenna type merits. That discussion has been underway for decades. Anyone who has operated 160 meters has his opinion, likely biased towards his particular use of the band.

There simply is no "best" antenna for all situations, but taking into consideration expense, ease of construction, and the ability to produce all-around performance, whether it be local or DX communication, the inverted vee dipole is probably the best compromise. Full-sized quarter wave verticals are popular with the DX crowd, but 160 meter pioneer W1BB leads them all with nearly 130 countries worked on an inverted vee.

In my general geographic location, three operators spent this past winter actively chasing DX and comparing results. Two stations were inverted vee equipped, the third had a full-sized quarter wave vertical. Letters from and on-air communication with DX stations throughout the world were interesting. The quarter wave vertical station ranked, on the average, slightly better for signal consistency compared to the inverted vees, but under certain conditions and over certain paths, the inverted vees took honors. An interesting comment came from a European, who said, "When the band is marginal, your quarter wave competitor may be copyable when you aren't, but when the band is open, your inverted vee is louder." Is this mixing and reinforcement of polarization? Possibly. You can find on 160 some unusual propagation and path quirks not found on any other amateur band. In the long run, the vagaries of propagation are the great equalizer so long as the antenna performs at the best possible efficiency.

If you have a tower topped with a high frequency tri or mono-band beam, can lay an adequate ground screen radial system (and I am not certain what is "adequate"), and wish low angle DX radiation, then by all means use the tower shunt fed as well-described in one or more previous articles.[1] A 3/8 wave inverted L type antenna is an excellent performer, provided it too is operated against a good radial system. The short, commercially available, base or center loaded 20 to 30 foot verticals are poor performers even used with a good radial system. Should you not want or be able to install a radial system, the inverted vee is likely the best all-around compromise 160 meter antenna, giving hours of enjoyable stateside contacts and doing a respectable DX job when the skip is long.

The inverted vee, however, is not to be constructed and installed in a haphazard manner. Set aside a Saturday afternoon and do it properly. To assist, here are a number of suggestions and tips that will ensure a well-performing installation.

1. Use number 14 or larger copperclad steel wire for the dipole.
2. The center insulator should be a 1:1 balun like the Palomar, which covers 160 meters, or the like. Be certain the balun selected does cover 160 meters. Many do not, have a low frequency cutoff around 3 MHz, and will not work at 1.8 MHz.
3. Cut the antenna length using the standard half wave dipole formula of 468/f(MHz) or 257 feet, 10 inches at 1.815 MHz.
4. Prepare the center balun/insulator and dipole wires according to the manufacturer's instructions.
5. On the dipole far ends, use 6 to 12 inch insulators similar to those made by Hy-Gain. Do NOT use "egg" type insulators.
6. Do not solder the dipole far ends after securing through the insulators. The antenna will have to be trimmed to resonance. The wires will be soldered after resonance determination.
7. Erect the center (apex) insulator/balun as high as possible. It should be a minimum of 95 feet high to obtain a between-leg apex angle of 90°. A 50 foot height will give an apex angle of 120° and is the *maximum* angle at which the inverted vee will exhibit low angle vertical radiation. A 90° to 100° angle is highly recommended, but with less than 90°, signal cancellation and severe loss of antenna efficiency will result. These figures place the antenna ends approximately 200 feet apart and at ground level. It is desirable to have the antenna ends elevated ten or more feet, if height capabilities per-

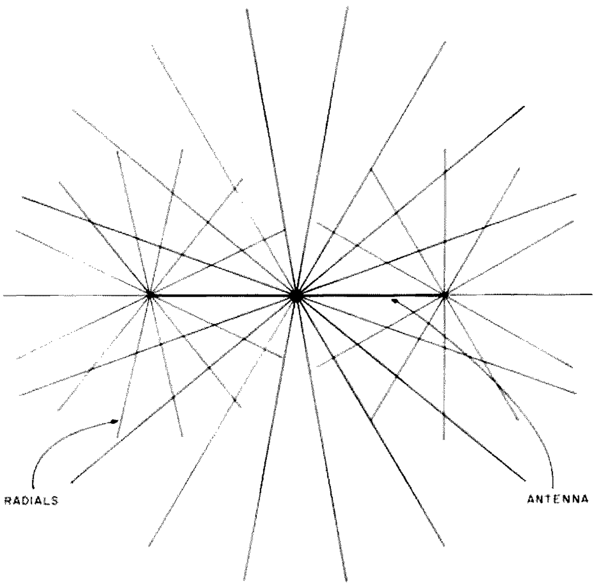

Fig. 1. Proposed ground screen radial system for 160 meter inverted vee (top view).

mit. It is also desirable to run the legs in a straight line, not folding them back upon themselves, but this may be necessary to fit the antenna into available space.

8. If the antenna center is to be supported by a metal mast or tower, it is recommended the center of the antenna be hung 3 or more feet off the support to minimize coupling. It is assumed any guy lines are broken with insulators into non-resonant lengths. Install the antenna as clearly as possible from guy lines.

9. The feed impedance of an inverted dipole is approximately 50 Ohms. The antenna may be fed with any popular 50 Ohm coaxial cable. At this frequency and amateur-allowed power levels of up to one kilowatt, there is nothing gained in using expensive RG-8 type cable. The much less expensive RG-58 type cable has very low loss and more than sufficient power handling capability at 1.8 MHz.

10. It is highly recommended that the feedline be made an *electrical* half wavelength or multiple thereof. A half wave length of foam dielectric coax, at 1.815 MHz, is 219 feet, 6 inches; solid dielectric coax has a length of 178 feet, 11 inches at the same frequency. These feedline lengths are calculated for 1.815 MHz. Should you elect operation in other available portions of the band, as shall be discussed briefly later, in addition to adjusting the dipole length, feedline length will need to be changed. Use these formulas for the calculation of an electrical half wavelength:

Foam

$$\frac{492}{f(\mathrm{MHz})} \times 0.81 = \text{length}$$

Solid

$$\frac{492}{f(\mathrm{MHz})} \times 0.66 = \text{length}$$

Any excess cable between the antenna and transmitter may be coiled, taped and placed out of the way.

11. Tuning the antenna may be accomplished through use of a reflectometer (swr bridge) or wattmeter having forward and reverse scales. Be certain the instrument is accurate at 160 meters. Many commonly available swr and wattmeters cut off around 3 MHz and are *entirely* inaccurate at 1.8 MHz. The least expensive swr meter having reasonable accuracy at 160 meters that I know of is the Swan SWR-3 at $10.95.

12. There are but two places to accurately measure swr: at the antenna feedpoint or along the feedline at the electrical half wave points. If you cut your feedline as described, you may do your measurements at the transmitter. Otherwise, if you want accuracy, measure at the antenna feedpoint. This may not be physically convenient, but a tuned antenna is our goal.

13. Initial swr measurements will most likely indicate the antenna is too long. This is expected due to a number of factors involving an inverted vee antenna. The antenna will need to be trimmed on *each* leg from 2 to 5 percent. Initial trimming may be up to 6 inches. Recheck the swr, trim again as necessary, but in smaller increments of 2 inches per leg.

14. Do not put absolute faith in an swr meter. If you have two, try both, being prepared to believe the one which shows the *highest swr*. Erratic readings, indication of reflected power varying under key-down conditions, may be diode saturation in the swr meter (use only as much transmitter power as needed for full scale forward reading), a faulty balun, or the like. If you are using an antenna tuner and it becomes warm or if you have difficulty loading the transmitter, suspect a problem in the antenna system that warrants immediate attention.

15. In practice you may not be able to obtain a 1:1 swr at the desired frequency. Trim for minimum swr, remembering that a 1.5:1 swr represents only 6.25% loss and a 2:1 but 11%. With the feedline cut as suggested, an swr of less than 1.5:1 is easily obtainable.

16. Inverted vee straight dipoles typically have a very narrow operating bandwidth rarely exceeding 25 kHz at the 2:1 swr points. Some additional bandwidth is possible using a folded dipole in the inverted vee configuration. Antenna and feedline lengths remain as previously described except the center balun/insulator will be a 4:1, such as a Palomar.

17. Observed radiation patterns of acute angle inverted vees suggest maximum radiation off the antenna *ends*, not broadside. Two inverted vees at right angles to one another are suggested for maximum coverage of all compass points. On certain paths, startling signal strength differences of 10 to 15 dB are not uncommon.

18. A remote-powered changeover relay may be used at the feedpoint for feedline switching between antennas. This saves the cost of one feedline but adds the cost of the relay and possibility of its failure some cold winter night. Separate feedlines are suggested.

19. Don't neglect waterproofing of connections. PL-259 connectors are not waterproof. Spray with several coats of a Krylon-type spray, wrap with good quality electrical tape and spray again.

Speculative Ground Screen Option

While I have not experimented with a ground screen radial system beneath an inverted vee, my speculation is that it may be worthwhile, particularly in locations having poor soil conductivity. Ground losses at 160 meters can cause severe absorbing of transmitted power. The suggestion would include bonding 20 to 40 radial wires to the tower base, the radial wires being .40 to .50 wavelengths long evenly spaced and fanned around the tower like spokes of a wheel. At the dipole ends and directly beneath them, a six foot or longer ground rod may be driven into the earth and bonded to it, another 20 to 40 radials each being .12 to .25 wavelengths long evenly spaced and fanned. Electrically it is not necessary to bury the radial wires.

Before undertaking the complete radial installation, try the first 4 radials directly

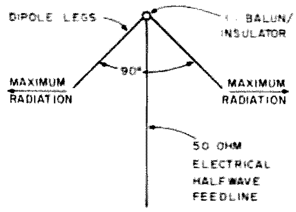

Fig. 2.

beneath the antenna center, spaced 90°. Place two radials directly beneath the antenna legs. I would anticipate a change in the antenna's resonant frequency which may be an indication the radial system would be worthwhile. Carefully controlled before and after signal strength measurements with the cooperation of a nearby colleague may provide meaningful information.

An inexpensive source of ground screen radial wire is the so-called electric fence wire available from Montgomery Wards, Sears Roebuck or most farm supply stores.

The Gentleman's Band

The 160 meter band is not an amateur band per se, but a shared band in which U.S. amateurs are permitted operation on a non-interference to LORAN navigational services basis. As protection to the LORAN service, the 160 meter band is segmented by frequency allocation and transmitter input power is related to geographic location. Traditionally popular segments of the band in the U.S. are 1.800 to 1.825 and 1.975 to 2.000 MHz. Over the years there has evolved a gentleman's agreement on usage. This agreement says that 1.800 to 1.810 is reserved for CW only, and 1.810 to 1.825 is for voice communication, although FCC regulation allows mixing of modes by not specifying CW and voice subbands. There is little U.S. CW activity elsewhere in the 160 meter band with the exception of Hawaiian stations operating between 1.995 and 2.000 MHz.

Furthermore, as relates to DXing, the gentleman's agreement says no U.S. or Canadian station may use 1.825 to 1.830 for transmitting, to allow foreign stations a segment in which to operate without being obliterated by VEs and Ws. This is the "DX Window." The agreement has worked quite well over the years with few exceptions. Five kilohertz of a 200 kilohertz band, or 2½ percent, is not too much to ask for those desiring to work international DX and as a courtesy to our foreign friends. Those who honor the agreement are commended, those who do not are respectively requested to be considerate.

If your 160 meter interest is DXing, your operation will likely be confined to 1.800 to 1.825, keeping in mind not to spill sidebands into the DX window by operating too close to 1.825 or 1.830.

If your interest is rag chewing and developing long-term friendships for which 160 is particularly noteworthy, you will likely wish to operate in those segments of the band allocated to your geographic location while keeping clear of frequencies around 1.900 where LORAN interference is fierce. This winter past saw much sideband activity moving into the 20 to 30 kHz above 1.830 and above 1.975 for QRM-free contacts. If these frequencies higher in the band are your choice, the previously given antenna and feedline formulas need to be recalculated.

Before operating 160 meters, be sure to check FCC regulations concerning power and frequency allocation for your area. The ARRL Operating Aid S-15A contains all necessary particulars. ■

Ten Meters: Dead or Alive?

- - a user's report

During the month of June, 1974, after twenty years of hamming, I was mighty close to pulling the big switch on all low band operations and contemplating 2 meter FM. Exchanging signal reports and the usual trivia no longer interested me. Nor was I going to continue the bothersome task of trying to pry QSL cards from Lower Outer Magnolia. No siree, 2 meter FM here I come!

By chance, I decided to go on ten meters, before selling all of my low band gear. It was sixteen years since I had been active on my old favorite band, during the peak of one of the highest sunspot cycles on record. Those were the days, my friend.

A strange thing happened that fateful evening. The band was open on a North-South path and the 4 call area was coming through loud and clear. Who said ten was dead? I heard multitudes of stations calling CQ ten-ten. It sounded like a group of newly licensed hams with cases of nervous jitters. Hence, the stuttering. Using my old Heath HR20, HX20 receiver and transmitter along with an inverted vee cut for 20 meters, I loaded up on ten with an swr of umpteen to one. I answered a CQ from a station in Birmingham, Alabama who had his friend on frequency with him.

We exchanged the usual trivia and then it happened.

"What's your Ten-Ten number? Do you have the Yodar Kritch?" he asked. I offered him my Social Security number instead, if he was interested, but I did not know what a Ten-Ten number was. As for the Yodar Itch or something, I told him I did not have it and asked if it was catching.

"Do you have a sweetheart," he replied?

"No!" I said. "I am happily married."

His friend broke in and asked if I was a liar. "It's all the truth," I said. 2 meters here I come, the quicker the better, I thought. Let me see what 2 FM holds forth. "To each his own," I mumbled.

I was getting ready to sign off when he said, "Wait, old man, and let me explain. To promote activity on ten during the lull of the current sunspot cycle, a group in California organized a net with chapters in many of the larger cities. Some foreign countries are also forming chapters and appointing their own chapter heads. The main body is called The Ten-Ten International Net of Southern California. All you have to do is collect 10 different Ten-Ten numbers if you are in the USA and 5 if you are out of the USA. You send the log information only, no QSLs needed, to the manager in charge of your call area along with a nominal fee," he went on to explain. "You will get your own Ten-Ten number along with a certificate, suitable for framing, plus quarterly newsletters. We are all having a ball and at the same time keeping ten alive and saving our band from being taken over by the CBers," he raved.

He explained that many of the chapters issue their own certificates for working a certain amount of their certificate holders. The Yodar Kritch is the name of a certificate issued by the Maryland, Washington D. C. chapter. In fact, its chapter head is Jim Hart WA3NCQ, so they also issue The SweetHART certificate for working five members. The LIARS stands for the Long Island Amateur Radio Service, a chapter serving the New York City, New Jersey metropolitan area. You can get more information by signing into their Thursday evening net on 28.620 MHz at 8 pm local time.

I apologized for my ignorance and asked just how many are now involved in this new aspect of amateur radio and isn't it pretty expensive? "We are well over the 9000 mark," he replied, "and the certificates are no more than one dollar. In fact, some are free. You don't have to go certificate-hunting if you're not interested, just collect Ten-Ten numbers. Bars, plaques and awards are issued for reaching different plateaus of achievements. Worked All States Ten-Ten awards are even issued. For this one you do need QSL confirmations. You can become a VIP in the Ten-Ten organization by collecting 500 numbers. 1000 different contacts qualify you for a plaque award. You can work up to these levels by submitting a list of each 100 you work, for which you receive a bar."

"Sounds mighty complicated," I said. "Did you hire a private secretary to do your paperwork?"

"On the contrary," he shot back, "it's pretty simple if you can keep an up-to-date card file and use a separate log for ten. It's like an eternal contest, worked on at your own pace. You will find us to be a group of very friendly chaps, all willing to help. None of the hanky-panky that you hear on some of the other bands."

"To each his own," I replied. "2m FM here I come! What is your Ten-Ten number? Just for my log, you understand."

As you have probably guessed, over two years have passed and I never did get on 2m FM. Two months after that fateful evening, I was already hooked with my own Ten-Ten number of 9732. I have collected many numbers since and have had the most enjoyable contacts in my twenty-two years of hamming. Over 13,000 numbers have been issued and it shows no sign of stopping. For twenty years I could have been considered a certificate haters club member. Today, I am the holder of many unique certificates issued by the Ten-Ten chapters. They would have to be seen to be appreciated. One of the certificates, The Raggedy Ann and Andy, is issued by Worth Gruelle K4VM. Worth, a renowned artist, the son of Johnny Gruelle who invented and originated the characters, issues the certificate in memoriam to his father. The different certificates issued now number over 50. They are too numerous to mention and many hold interesting stories behind their origina-

tion.

Propagationwise, ten meters appears to be the twilight zone of HF and VHF characteristics. It's fascinating to observe the effects of backscatter and tropospheric bending. Sporadic E propagation found on ten seldom appears on fifteen meters. It is a rarity on six and will reach a maximum of maybe 70 MHz. Freak conditions, at times, will cause it to appear higher.

Ten meter beacons are being transmitted from almost all continents of the globe as a guide to conditions. This is evidence enough to show the increasingly wide interest being shown on this band.

It is ironical to hear so many newcomers to this band comment that they haven't been on ten for years. They thought it was dead. Many skip contacts are being made and at times when fifteen and twenty are dead. True enough, if no one went on, it would appear to be dead. How surprised many would be if they tuned their receivers to ten.

Antennas need not be cumbersome. When conditions permit, many long haul contacts can be made much easier on this band with simpler antennas and lower power then is needed on the other lower frequency bands. QRM problems appear less frequently due to the huge frequency spread.

I want to thank Mike WA4BNU and Ron WB4ASV both of Birmingham, Alabama, the home of the All American Cities chapter, for taking the time to initiate me into Ten-Tenning. My appreciation also goes to the Long Island Amateur Radio Service (LIARS) and its chapter heads past and present, Rich WB2MAN, Jack W2KDI, and all of their officers and members for their dedication to keep ten alive, along with many others who all share in using ten and enjoying it. ■

New Products

HEATHKIT HW-2036 SYNTHESIZED 2 METER TRANSCEIVER

Do you do a slow burn every time your old buddy comes on the air and brags about his brand new synthesized rig? Does he rub in the fact that what he paid for it roughly equals a month's pay for you? Do you get the old here-we-go-again feeling every time a new repeater comes on in your area and you spring for a new set of rocks? Well, there's a solution. For $269.95 you can get yourself a fully synthesized 2 meter rig with specs and features equaling radios that cost over twice as much.

I'm talking about the *new* Heathkit 2036. I have to stress the word new since in all probability many operators will remember what happened in 1975 with the 2026. To refresh your memory, the 2026 had a spur problem which was difficult to correct without a spectrum analyzer, something you just don't find in every shack. Heath, however, set things right by doing something that is extremely rare in the merchandising business — they took back the rigs, refunded money in full, and went back to the old drawing board.

After a year of redesigning, the successor has arrived. The HW-2036 has solved the problems. Heath says the spurs are now down 70 dB within 20 MHz of the carrier and their spectrum analyzer photos back this up. So it seems that now we can operate without worrying that every repeater within range will be set off.

The HW-2036 has the solid look and feel that hams have come to expect from Heath amateur equipment. The unit weighs 6½ pounds and features the usual turquoise blue finish. The folks at Heath have provided the multi-packaging of their kits with a large number of parts. Six sub-packs keep all those little parts well separated until they are needed. The manual hefts out at 160 pages and is in keeping with the Heath tradition of step by step crystal-clear directions. A separate fold-out section contains all the pictorials so they can be conveniently mounted over the work area for easy perusal.

The HW-2036 is definitely not a quickly-assembled one evening kit. There's a large number of parts and quite a few steps to assembly. Five circuit boards are involved. They're interconnected with a pre-assembled wiring harness. Access to the boards for the big step of alignment is excellent. There are eight sections involved for a total of nearly 100 alignment steps. For this, you need a VTVM or high-impedance VOM, as well as a receiver that tunes WWV. Even better, use a frequency counter that reaches 150 MHz. Although the steps are quite time-consuming, alignment isn't a terribly complicated procedure. Any 2 MHz segment of the 2 meter band can be selected.

On a weekend trip, I worked a number of repeaters in the New England area. Just about everyone I talked with commented on the clean and crisp audio output. Remarks like, "It must be a Heath" were common. The rig features a 10 Watt output, which was adequate for all but the fringe areas. I'm a bit spoiled anyway since my old rig ran 45 Watts. My impression is that one can get along just fine without an external amplifier, considering the proliferation of repeaters.

The economy-size illuminated meter is a joy to use. It shows both received signal strength and relative rf output. A bright green LED situated next to the meter pops on to show there is a signal being received.

A red LED labeled "Synth Lock" lets you know when the synthesizer is not locked to frequency. If you don't notice it and the unlocked condition lasts for more than one-half second, the transmitter is automatically disabled by a safety circuit to insure that you won't accidentally operate outside the band. Another fail-safe built into the HW-2036 disables the transmitter if you dial above 147.995 or below 144.00. If you're into MARS or CAP, don't despair, since this can be defeated by the simple act of removing a jumper on one of the circuit boards.

I found it helpful to put a small hooded light over the channel selector switches so I could more easily set them at night.

Heath told me that they had been having a few complaints about audio with the HW-202. Checking into them, they found that some customers had put non-standard mikes on the units. To eliminate this problem on the HW-2036, they made the mike non-detachable.

I've always wondered why Heath mikes are white. On a dark New Hampshire night, I found out. Having no mike clip on the dashboard, I have to lay the mike on the dark colored upholstery. This requires a good deal of groping. With the shiny white mike, my problem was solved.

The HW-2036 can be ordered with either the standard mike for $269.95 or with Heath's Micoder featuring a built-in Touchtone pad for $299.95. That's a savings of 20 bucks over the Micoder alone.

Adding to the list of built-in features is a subaudible tone encoder. Three switchable tones can be set during alignment in the 70-200 Hz range.

A logical accessory for the HW-2036 is the HWA-2036-3 power supply. Selling for $32.95, this easy one-evening project supplies 13.8 V dc at up to 2.7 Amps. It features 1% regulation and 0.1% ripple.

For those who are interested in specs, here are a few for the HW-2036. The receiver sensitivity is 0.5 uV for 12 dB SINAD, which comes out to 15 dB of quieting. Audio output is typically two Watts. I-f rejection is greater than -80 dB. while trying various repeaters, I found a very noticeable birdie at 147.00 MHz. While puzzling about this problem, an early-morning call from Heath shed light on what happened. It seems the first production run of the HW-2036 had a bum FET in the synthesizer board which resulted in that birdie. No units with this were shipped to customers. Heath assured me that the inclusion of the correct part would eliminate the birdie problem completely.

The transmitter is capable of taking a 100% duty cycle into an infinite VSWR. Offset crystals are supplied for plus and minus 600 kHz with provision for one extra. Current consumption is 700 mA on receive and 2.6 Amps on transmit.

The HW-2036 is a pleasure to build and to use. You'll have to look pretty far to find all these features for a price of $269.95. It's by far the lowest cost synthesized 2 meter rig on the market and is sure to find an immediate niche. If you want to stop collecting rocks and the piggy bank isn't full enough for one of the big ones, this is sure to be the rig for you. *Heath Company, Benton Harbor MI 49022.*

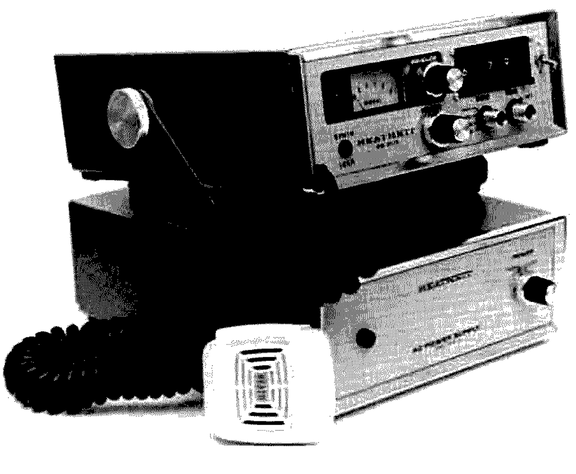
THE VHF ENGINEERING SYN II SYNTHESIZER

VHF Engineering of Binghamton NY has announced their new SYN II synthesizer, a high quality synthesizer designed for use into virtually all two meter rigs available on the market today.

The VHF Engineering SYN II synthesizer is designed to operate over a frequency range of 140 to 149.995 MHz in 5 kHz steps, and is compatible with two meter equipment that uses transmit crystals in the 6, 8, 12, or 18 MHz range and receive crystals in the 15 or 45 MHz range. The SYN II synthesizer may be used with either FM or phase modulated transmitters and may be operated with either mobile or base transceivers. The SYN II synthesizer features unique i-f programming which permits the unit to be used with receivers having i-fs in the range of 100 kHz to 30 MHz. Detailed programming instructions are given in the construction manual so that the builder may select the standard 10.7 MHz i-f or any other i-f frequency in the permissible range. This feature permits use of the SYN II with older commercial equipment as well as currently available two meter units. Standard repeater offsets of +600 kHz, -600 kHz are provided along with 3 user selectable offsets in 100 kHz steps. This feature permits the user to operate standard repeaters



as well as repeaters with unique offsets. A modification kit is available for MARS and CAP offsets.

The VHF Engineering SYN II synthesizer kit consists of high quality epoxy glass circuit boards, computer grade components, thumbwheel switches, stylized cabinet, and a detailed construction manual. The kit is complete and requires no additional components. The price of the kit is $169.95; wired and tested $239.95; programmed to your equipment $249.95. *VHF Engineering, 320 Water St., Binghamton NY 13902.*

THE KLM ECHO 70 432 MHZ SSB/CW TRANSCEIVER

If you have longed to explore the world of 432 MHz, Echo 70 may be the answer. Heretofore, 432 equipment for SSB has been mostly a matter of homebuilt type equipment. Thanks, in part, to the popularity of AMSAT's OSCAR satellite, KLM has filled a void for a reliable compact piece of gear for the OSCAR up-link. The KLM Echo 70 is imported by KLM from Japan where it is known as the "Liner Four Thirty."

If OSCAR is not your bag, then maybe 432 DX will interest you. With those super KLM antennas there should be no problem making sufficient contacts on the band to keep up your interest. We are fortunate in the South Jersey area to be within range of a good deal of activity from the New York-New England area and from across the river in the Philadelphia area.

One can't help but be impressed by the Echo 70; from the time the packaging is removed, it is a physically attractive and sturdy-looking piece of gear with the controls well laid out and convenient to operate. The unit comes complete with a dynamic mike, mounting bracket and dc cord, and is ready for mobile operation as is or can be set up in the shack with the addition of a regulated 12 V dc supply good for about 5 Amps maximum. When used in this manner I would strongly recommend the use of KLM's model 432-16-LB 16 element antenna which sports a gain of 15 dB and is rather compact with its 12 ft. boom length. Be sure to use low loss, jacketed or hard line coax for those extra long runs up the tower. The *VHF Handbook* gives 5 dB attenuation per hundred feet for regular RG-8/U at 420 MHz.

Now let's take a look at how the Echo 70 operates. The unit covers two segments of the band: 432.00 to 432.480 MHz and 435.00 to 435.480 MHz. These ranges are switch selected from the rear panel. Having selected the operating range, the tuning knob on the front panel features a direct readout channel display (similar to an FM rig) which ranges in steps from 432.01 for channel 1 to 432.47 for channel 48, or 435.01 to 435.47, and a VXO control with 20 kHz divisions for total coverage between each channel.

The receiver has an RIT control which can be switched in or out of the circuit for additional excursions of plus or minus 2 kHz from the transmit frequency. An effective noise blanker may be switched in by means of a front panel push-button. Upper or lower sideband is also push-button selected from the front panel. The power, volume and squelch controls are concentrically mounted in the upper right corner of the front panel. An unusual and convenient feature is built in to the front panel when the VXO is in the off position. This feature is called an "Auto Watch," which allows the receiving frequency of each channel to be swept automatically. The auto watcher will not respond to weak signals but will detect, by a beat note, stronger signals within the range of each channel, which after they are detected can be "tweaked in" with the VXO.

Reports of an excellent sounding signal have resulted on both SSB and CW with power output in the ten Watt range, giving excellent coverage with a good antenna. Solid state amplifiers are available should you choose more power.

Although not measured, the receiver sensitivity seems excellent and well within the 0.5 uV for 10 dB s/n claimed by KLM. The quality of the small internal speaker is fine and provides sufficient audio output.

Additional operating controls include a mike gain (accessible from the right side panel) and rear panel controls for SSB-CW, frequency range, key jack, external VFO switch and VFO input jack, a relay switching control and external speaker jack. The mobile mounting bracket doubles as a fine stand for the operating table.

To be fair, any equipment report should include the negative as well as positive factors under review. This is an honestly difficult task but nonetheless a few items were uncovered. My major "gripe" is the oddball CW jack on the rear panel for which KLM did not provide a plug or adapter. For those of you who care to use it (I do not, except for contest work), a VOX circuit would be a handy addition or option.

I think the first sentence in the Echo 70 operating manual is an appropriate closing line for this article. "The unit is the very first 432 MHz band SSB transceiver that has ever been manufactured in the world. Nevertheless, it is a compact and cozy piece of equipment with prominent performance." *KLM Electronics, 17025 Laurel Road, Morgan Hill CA 95037.*

VHF ENGINEERING 2M TRANSCEIVER

It started with my desire to build a 2m mobile rig that wouldn't take up much space. After running a converted GE mobile phone rig, which took up most of the storage area in the cab of my pickup, it was obvious that the answer was to go solid state. VHF Engineering seemed a logical choice, since I could mix and match their components and custom design my own system.

A phone call to Tufts Radio in Medford MA brought a 2 meter transmitter strip (TX-144). I decided to start with the transmitter because I wanted to get a look at the way VHF Engineering products went together before I acquired the remaining components for my transceiver. The kit was easy to assemble, with all PC boards well laid out, and a sensible set of instructions. Construction took two evenings, and with a #51 light bulb, talking across town was a snap. With a 19" ground plane the Concord NH repeater, some 30 miles away, yielded good to excellent signal reports. The one Watt transmitter strip proved to be quite a performer, with several stations reporting good audio.

All doubts about VHF Engineering cast aside, it was time to order a receiver. Again a call to Tufts . . . and again prompt service. The RX-144D receiver, like the matching transmitter, was easy to build, and provided almost instant satisfaction. Assembly time was about double, including alignment. The major change in the 144D over previous VHF Engineering 2 meter receivers is the elimination of variable capacitors for alignment purposes. Instead, VHF has switched to slug tuned coils, and the results are encouraging. Aside from the ease of alignment, the coils are bound to last longer. Noise is reduced, since dirt can't get into coils as it can into capacitors . . . plus there's the question of corrosion, since silver plated capacitors are bound to detune after an extended period of all-weather use. Here in New Hampshire, with our wide changes in temperature, it's best not to take any chances, and I'll take coils over capacitors under those conditions anytime.

With receiver and transmitter up and running, the next question was an enclosure. After searching through everything I had around, it became obvious I would have to buy some-

thing. Then VHF Engineering announced production of a cabinet kit, with relay knobs, speakers, volume and squelch controls. I couldn't resist.

Take a look at VHF Engineering's product line and it's easy to see why you can custom design your own rig. Scanning decks, accessory filters, amplifiers, even synthesizers are available. I opted for a 10 channel scanning deck and 1x25 Watt amplifier. In the VHF Engineering case it all fit like a glove. Really nice layout, with lots of room for even the most all-thumbs constructor.

On-the-air operation is actually more fun than building the kits (although I had my doubts while building, since I kept coming up with more accessories). Reports have been most satisfying, and the pride of knowing I not only constructed the gear, but custom designed it as well, doubles the fun.

I've already started work on my 432 rig, and 220 isn't far behind. By the way, if economics is any consideration, my entire 25 Watt 2 meter mobile ended up costing less than $225. Can you beat that? *VHF Engineering, 320 Water Street, Binghamton NY 13901.*

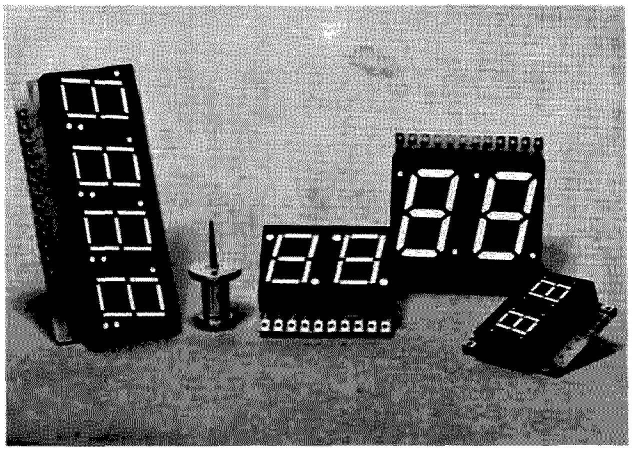
NEW MULTI-DIGIT LED NUMERIC DISPLAYS FROM NATIONAL SEMICONDUCTOR

A new series of light emitting diode display numerics are now being manufactured by National Semiconductor Corporation, according to Bob Santos, Marketing Director for Optoelectronic Products. This series of multi-digit GaAsP reflective displays represents the latest in design advances in 0.3, 0.5 and 0.7 inch formats, Mr. Santos said. "They provide the designer with an effective, easy to implement answer to the need for an inexpensive large numeric display for use in a wide range of applications."

Basically 2 digit and 4 digit displays, the units can be stacked on end for uses that require additional digits. (The 2 digit displays are known as the "NSN" series, and the 4 digit displays are the "NSB" series.) When combined with the options for overflow, polarity and other indications, virtually all display requirements can be satisfied. Both the common anode and common cathode forms are available with direct drive and multiplex versions, providing a great deal of versatility to the designer. Printed circuit board type terminals on the edges of the display are used for electrical contact.

The optical design of this display series creates a distinct, easy to read display with a wide viewing angle, as well as excellent on-off contrast and segment uniformity, making these units suitable for use in test and measurement equipment, consumer products, instrumentation, industrial controls, digital instruments, desk top calculators, clocks, TV channel indicators, and other applications. The series features a typical digit light intensity at 10 mA of 1.6 mcd.

Pricing per digit in lots of 100 pieces is $1.80 for the 0.3 inch, $1.90 for the 0.5 inch, and $2.00 for the 0.7 inch sizes. *National Semiconductor Corporation, 2900 Semiconductor Drive, Santa Clara CA 95051.*

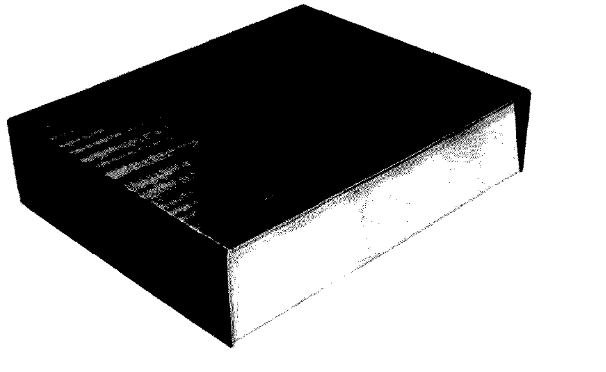


CASES ENHANCE CUSTOM-DESIGNED INSTRUMENTS

A new line of economical enclosures, in two sizes and numerous attractive colors and finishes, gives desk-top instruments an appearance contemporary with sophisticated electronic components and systems. Designated "Cono-Cases" by Vector Electronic Company, the WA series enclosures incorporate a ten degree sloped front panel and an optional smoked plastic facing for behind panel indicators. A recessed rear panel protects input/output connectors.

The enclosures, assembled from two interlinked channels, allow easy access to circuits, accessories and wiring. The lower section forms a chassis integrated with front and rear panels. Elongated holes in the bottom and rear panel provide superior convection cooling. The upper section serves as top and side panels. The WA1 enclosures are 11 inches wide by 8 inches deep by 4 inches high, giving 307 cubic inches of circuit space.

The WA2 enclosures are 14 inches wide by 11 inches deep by 4 inches high, providing a 560 cubic inch working volume. Construction of 0.062 inch (14 gauge) aluminum insures adequate support for transformers, heat sinks and other heavy components.



Cono-Cases are available with clear anodize satin finish, or with blue or walnut grained vinyl on the cover. Other colors available in anodize, vinyl or paint on request.

A full line of circuit boards and packaging accessories supports the enclosure line.

The WA series enclosures are priced from $12.95 to $19.70, depending on model and finish. They are available off-the-shelf from Vector and will be available through the firm's distributors throughout the United States and Canada.

Vector is a major manufacturer of sockets, terminals, connectors, printed circuit boards, card cages, enclosures, and complete packaging systems. *Vector Electronic Company, 12460 Gladstone Avenue, Sylmar CA 91342.*

ENGINEERING SPECIALTIES SYNTHACODER 22

What the heck is a Synthacoder? And why does every Icom 22S owner need one? The answers lie in the design of Icom's new radio, a diode matrix synthesizer which puts an end to crystals forever. (See New Products, Holiday '76 *73*.) Synthacoder is obviously a combination of synthesizer and encoder, and encoding is just what the device does. It makes the 22S a lot more fun to use, but still keeps the price tag low.

Using the Synthacoder, you can put the 22S on any common or 15 kHz simplex or repeater pair with a flick of four thumbwheel switches. Program the 22S for 21 channels of your choice using the diode matrix, and plug the Synthacoder into number 22. A trip into unknown repeater territory becomes a snap, provided your *73 Repeater Atlas* is handy.

Fact is that due to space limitations on the diode matrix, the 22S cannot be programmed for every standard repeater pair. You can cover non-split channels from 146.01 through 146.37 and up from 147.00 to 147.24 MHz before running out of channels, but that leaves five standard pairs unavailable, not to mention simplex and splitter pairs. The solution is obviously an outboard encoder.

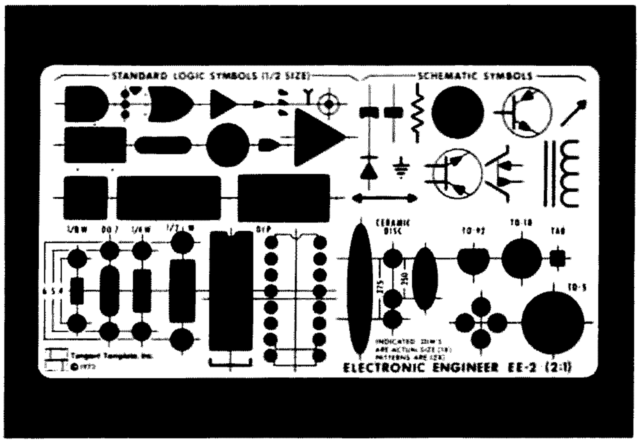
Many folks think they can outboard the 22S with a single ROM or even a few thumbwheel switches. You can, but to figure out what channel you're on takes enough charts and calculations to make the average weekend sports car rallyist cringe.

The Synthacoder allows *direct* readout of frequency, through a complex system using CMOS bipolar logic. The manufacturer won't say much more than that about his design and I suppose his reluctance is understandable. The competition is reportedly fierce to produce devices like the Synthacoder, with more than the 22S in mind. The smart money says Icom's idea will soon be appearing in other rigs, eventually eliminating the need for crystals. If diode matrix synthesizers do become the VHF economy rage, the Synthacoder will have a definite edge on the rest of the pack.

One big reason for Engineering Specialties leadership is price. Complete with wiring harness, hardware and fully assembled, the Synthacoder retails for $74.95. That puts the cost of an outboard programmed IC-22S under $320. Two hundred dollars more would be required just to equal the Icom receiver and super frequency flexibility.

Installation is quite simple, using the 9 pin accessory socket built into the 22S, to bring the Synthacoder's encoding lines into the Icom's diode matrix. Power is supplied by installing two pins in the standard 12 volt socket. (Icom conveniently left the two pins vacant.) The Synthacoder then is easily connected and disconnected from the 22S, and mounted with strips of velcro attached to the Icom mounting bracket. The unit is super compact, with a single PC board, and dimensions of 3¾" wide by 1½" high by 6" deep. It weighs less than 6 ounces and is packaged in a brushed and anodized aluminum case.

Dialing up frequencies with the Synthacoder is easy, although seeing the thumbwheels in the dark is impossible. (Engineering Specialties is working on an illumination kit, but I'm confident most hams will devise some type of lighting system of their own.) Otherwise there isn't a glitch to be found with the unit. It's very easy to count up and down without taking your eyes off the road, because the thumbwheels have a very positive feel.



The Synthacoder will not allow non-15 kHz frequencies, which the Icom will reject anyway. Instead the unit automatically disables the transmitter and turns on a bright red LED warning lamp labeled "Invalid Code" if you hit one of those non-standard frequencies.

Last month, after reviewing the 22S, I was left with the impression I'd be hard pressed to find 22 different channels to program into the Icom's diode matrix. I was wrong. After a trip into the New York City area with the 22S and matching Synthacoder, I vowed never to leave New Hampshire without the encoder. Not one repeater was out of my reach. And I'd successfully avoided the $500 dollar club in trying to put together a flexible, synthesized 2 meter mobile. And with the money I saved it was easy to finance a linear amplifier. *Engineering Specialties, PO Box 2233, 1247 Commercial Avenue, Oxnard CA 93030.*

NEW GENAVE VHF TRANSCEIVER

General Aviation Electronics, Inc. (GENAVE) of Indianapolis, Indiana, has introduced a new 25 Watt, high band transceiver. The unit comes in two models – the GMT-125 and the GMT-225.

The GMT-125 is called the "economy workhorse" of the GENAVE line. Modestly priced at $345, the transceiver will operate between 143.9 and 173.4 MHz.

The GMT-125 is a one channel transceiver and includes a 4 pole monolithic crystal filter. The inclusion of the crystal filter means that in most areas there is no adjacent channel interference. An 8 pole monolithic crystal filter is also available for those high density areas. A built-in heat sink enables the unit to operate longer and more effectively. Included with the GMT-125 is a captive microphone.

The GMT-225 is the deluxe 25 Watt model. The transceiver has all of the same fine features as the GMT-125, including a 4 pole monolithic crystal filter and built-in heat sink. The GMT-225 does include the addition of another channel, making it a two channel transceiver, and substitutes a plug-in microphone for the captive microphone. The GMT-225 is priced at $360.

Included with both the GMT-125 and the GMT-225 are microphone, microphone clip, dc power cord and mounting bracket. Weighing only 6 lbs., and operating on 13.75 V dc, the units are easily installed anywhere.

The subaudible tone squelch is one of the most advantageous accessories for the GMT-125 and the GMT-225. The tone squelch allows your receiver to be activated only in response to calls placed within your own system. No distractions by everyone else's transmissions!

Other accessories available for both units include portable power pack (allowing portable operation), external speaker and 12 Watt PA horn.

Also available are antennas for trunk lip mount, magnetic mount, and drill through mount. *General Aviation Electronics, 4141 Kingman Drive, Indianapolis IN 46226.*

THREE FUNCTION TEMPLATE SPEEDS CIRCUIT DESIGN

The Electronics Engineer template incorporates on one template the most commonly used logic, schematic and component layout patterns required for the majority of electronic circuit design applications. Each template includes a complete set of half size logic symbols and basic schematic symbols for preparing circuit diagrams. Component layout patterns include capacitors, resistors, diodes, transistors, ICs and a DIP.

The template is designed expressly for use by electronics engineers, circuit designers, technicians and draftsmen. The Electronics Engineer template is available with 1:1, 2:1 and 4:1 component patterns. EE-1 (1:1), $5.00; EE-2 (2:1), $5.50; and EE-4 (4:1), $7.50. *Tangent Template, Inc., P.O. Box 20704, San Diego CA 92120.*

NEW CATALOG AVAILABLE

Hamtronics, Inc. announces publication of a new catalog, which is available on request. This new edition features a new miniature VHF receiver preamplifier, a receiver multicoupler allowing the use of two receivers on a single antenna, and a low cost FM signal generator. Previous products include VHF and UHF FM receivers and transmitters in kit form and various adapters for use with VHF and UHF equipment, such as scanner adapters, multichannel adapters, and a full line of preamps. This new 16 page catalog is yours in exchange for a self-addressed stamped envelope. *Hamtronics, Inc., 182 Belmont Road, Rochester NY 14612.*

"WIRELESS" CONTROL COAXIAL RELAY

One coaxial feedline can be used for two antennas with Inline Instrument's Type 105 Wide Band Switching System consisting of a coaxial coupler and an SPDT coaxial relay. The coupler causes the coaxial cable to conduct both the rf signal and the energizing voltage to the remote coaxial relay, permitting one of two antennas or other loads to be selected at their source. Power capability is 1250 Watts CW from 1.5 to 60 MHz, 1000 Watts CW from 60 to 100 MHz and 750 Watts CW from 100 to 180 MHz. Other features include: negligible swr and insertion loss, weatherproof construction, no insertion noise, and 10,000,000 switch transfer life expectancy. Use of this system minimizes wind resistance, weathering and maintainance associated with multiple cables. Price is $49.95 (1 system). *Inline Instruments, Inc., Box 473, Hooksett NH 03106.*

200 lb. Cookie

- - microwave repeater control

Each repeater owner has his own favorite way to control his repeater, be it an on-site system with an on-off switch or the most elaborate of UHF radio systems. In remote control systems, the two most popular today are UHF radio remote and telephone remote. Both have drawbacks in an area like Los Angeles. First, the majority of our repeaters are located atop rather large mountains that can be a toll call away, and calling your system to activate one of your many remote functions can become quite expensive. For that reason, UHF remote control has become very popular out here, because there is a one shot investment and that's it. The drawbacks though, can be twofold. In Los Angeles there is virtually no unused spectrum available on the 450 band and it has been that way for many years. Obtaining a clear spot for a control link can be a job and a half. So, if a system already has an allocation, why change? Security and dependability – these are the key reasons for Burt Weiner K6OQK's decision to install a point-to-point microwave control system from his home in the San Fernando Valley (fondly referred to as "Burt's Pumpkin Patch") to his repeater in the KPFK transmitter site on Mt. Wilson.

For many years Burt has alternately controlled WR6ABE on telco lines and UHF, but has encountered the drawbacks previously discussed. Finally, upon acquiring some microwave equipment, he decided to make the big break from tradition and install the equipment as control for his system. Another reason was the pride he takes in the overall quality of the system itself. To listen on the output and then alternately switch to the input, one will note that many of the repeated signals out of ABE sound much better than its receiver is hearing. A look at the repeater itself will easily explain the reason. While the receiver and transmitter are quite standard early vintage Motorola, the equipment between them is state of the art broadcast quality. Burt, a broadcast engineer by profession, has taken a lot of care with the audio and carefully processes every word the receiver hears before the transmitter gets it. His technological wizardry can make even the raunchiest signal sound fairly passable. Since ABE's site also functions as a remote for the weekly "Mt. Wilson Repeater Assn. Amateur News QST Bulletin" and the audio quality via the telco lines was nothing to brag about (and since he was quite familiar with the improved quality that could be had by feeding the "News Service" to the transmitter via a microwave link), the decision to implement was made.

The accompanying photo taken on Mt. Wilson at the "Pumpkin Patch" tells part of the story. Burt and his compatriots have the ability to make even the hardest job a labor of love . . . you have to love what you are doing to truck a 200 lb. dish up a 5000' plus mountain, install it, and then go home and climb your 70' tower with another 200 lb. dish.

While still in the experimental stages, eventually WR6ABE will be on a full time microwave control system with limitless capabilities. At any rate, it is at least another first for southland open repeaters as far as we know. ■

Weather Satellite Simulator

-- do-it-yourself satellite?

This satellite may never fly, but it does speak exactly the same language as the weather satellites we presently have in orbit. There are a number of articles already available describing monitors for copying these transmissions.[1] Some are complete monitors and others describe how to modify your SSTV monitor to add this feature for a very small fee. These articles also describe the different set of standards used by this service, so I will touch on them only briefly, and only as they apply to this project.

The project is an adapter that goes with another item by Dr. Robert Suding WØLMD in the July 1975 *73 Magazine*, page 98. This article described a generator of accurate audio tones using a crystal timebase, and then TTL ICs to divide down to the required audio. By using a very accurate and reliable (and quite inexpensive) generator like this to feed my adapter, you end up with a gray scale generator for use in setting up SSTV monitors to very accurately decode and display weather pictures.

The standards used by these satellites very briefly are: 1. The transmission to Earth is an FM modulated (approximately 10 kHz deviation) carrier in the 135 MHz region. 2. The FM modulation is a 2400 Hz tone. This 2400 Hz tone is AM modulated giving picture and sync information that is equal to the instantaneous percentage of modulation – 0% is black, 80% is white, and 100% is sync. 3. The sync is sent just before each horizontal line for 12.5 ms (APT-satellite). 4. The horizontal rate is 4 Hz or 1 line every 250 ms (APT). 5. The total picture length or vertical scan is 200 seconds for 800 lines resolution (APT). 6. The aspect ratio is 1:1 just as in SSTV transmissions. The articles describe exact times, days, frequencies, and information required to copy pictures and are highly recommended reading for those intending to try. These standards as they apply to this adapter concern only the horizontal, vertical, and sync information and how they each relate to the percent of modulation and its use here.

Where to Start

I believe someone once said that for rabbit stew you first need a rabbit! In this case that would be to build the WØLMD generator. Other stable sources could be used, but this unit is so versatile it is more than worth the extra effort. One addition is suggested and can be included in the original generator if you choose, by using the 12th position of the rotary switch marked "frequency selector." This would be a good addition even if you don't build the adapter, since it gives you a very good source of 2400 Hz used for the weather satellites. If you have an SSTV monitor, the modifications to make it work in "satellite mode" are so few, and the addition of a 2400 Hz position to the generator so easy, that it seems silly to do without either. Further, the 2400 Hz tone is also very close to the bandpass edge for present SSB filters (2.5 kHz) and should prove useful for things other than satellites.

The modifications required to the WØLMD generator are as follows: 1. Add one more 7430 TTL IC to the parts required, and wire it into the circuit for +5 V and ground just as the other 7430s using pins 14 and 7 respectively. 2. Wire pin 1 to the "frequency selector" rotary switch position "L", the 12th or extra position. 3. Wire pin 8 (output) to pin 11 of the 7430 that has "1200" at pin 1, "2300" at pin 6, etc. This is one of two 7430s just before the 7402, and has +5 V wired to pin 11 in the original generator. 4. The remaining pins decide what frequency causes an output to occur on pin 8 of your added 7430, and are wired to outputs of the three 74193 "countdowns." Pin 2 is wired to "1024", pin 6 of the third 74193. Pin 3 is wired to "256", pin 3 of the third 74193. Pin 4 is wired to "64", pin 6 of the second 74193. Pin 5 is wired to "16", pin 3 of the second 74193. Pins 6, 11, and 12, the remaining input pins, are wired to the +5 V bus. When the "frequency selector" switch is set to position "L", a 2400 Hz output results. This is the extent of the modifications if all you wish is a 2400 Hz source in addition to the original frequencies.

Generating a "Gray Scale" Satellite Picture

By building an additional adapter, the added 2400 Hz tone may be changed into a gray scale generator signal. This requires only a few more TTL ICs, and is quite inexpensive. For setting up a monitor for accurate presentation of the weather pictures it is hard to top, as it provides a gray scale pattern including the 0% black, 80% white, and 100% sync signals mentioned earlier.

Since the adapter requires an unusual clock signal as well as the very accurate 2400 Hz from the WØLMD unit, a complete countdown chain required for the satellite reception and presen-

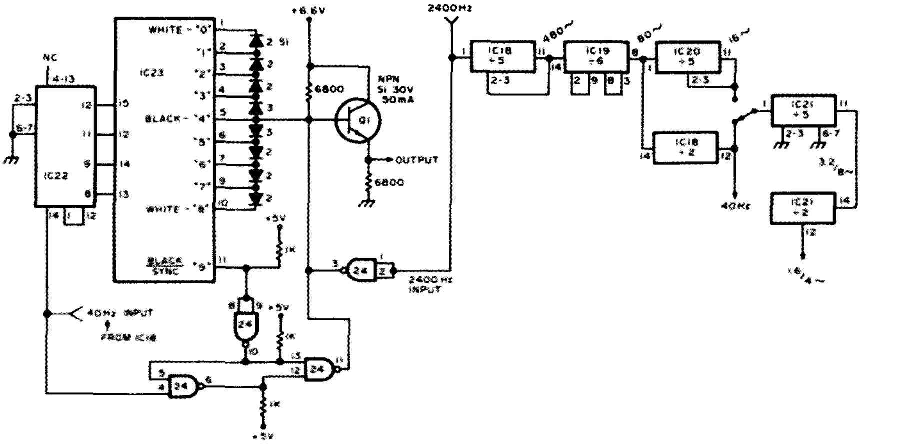

Fig. 1. Q1 emitter: "0" = 0-4.8 V; "1" = 0-3.6 V; "2" = 0-2.4 V; "3" = 0-1.2 V; "4" - 0 V; "5" = 0-1.2 V; "6" = 0-2.4 V; "7" = 0-3.6 V; "8" = 0-4.8 V; "9" = 0 V/0-6.0 V. IC18-22 (7490): pin 5 = +5 V; pin 10 = ground. IC23 (7445): pin 16 = +5 V; pin 8 = ground, IC24 (7403): pin 14 = +5 V; pin 7 = ground.

tation is included as part of the adapter. Build it in its entirety and you have all the timing signals required for your satellite ground station.

The 2400 Hz square wave from the WØLMD unit enters the adapter unit and is sent two ways (see Fig. 1). The first is to the input of the gray scale generator and one pole of a switch that allows straight through operations. The second is to a countdown chain of dividers that ends up providing the basic signals of 1.6 and 4 Hz used for horizontal scanning on each of the satellite's two modes. Included in this slightly different arrangement of dividing is a source of 40 Hz (a 25 ms period). This 40 Hz signal drives the 7490 counter, IC22, which in turn causes IC23, a 7445, decoder's outputs "0" through "9" to go low for a 25 ms period each. If further gating were not used, this would result in an output from Q1 emitter of ten 25 ms long outputs. The 7400, IC24, is added to cut one of these outputs into two 12.5 ms periods. These three ICs are the only ones that really comprise the gray scale generator, and their cost at going rates is approximately: 7490 — .76, 7445 — 1.10, and 7403 — .19, for a total of $2.05. A word may be in order here about the IC numbers since I used IC1 to IC16 for the original WØLMD unit, IC17 for the added 7430 to get 2400 Hz, IC18 to IC21 for the timebase countdown dividers, and then IC22 to IC24 for the gray scale generator. Simple as that.

While the diode arrangement around the IC23 outputs may not be unique, I have not seen it elsewhere; I frequently use it to make up various staircase generators. With the added IC24 gate, these diodes cause a 5 level staircase, first descending, then ascending, for the positions "0" to "8" of the 7445 IC23. The staircase is formed as follows: 1. Position "0" going low through nine diodes (junctions) causes a voltage of approximately 9 times .6 V, or 5.4 V, at the base of Q1. For 25 ms (one clock period) this is as *high* as the base of Q1 can go. Meanwhile, at the output of IC24, pin 3, 2400 Hz transitions are occurring throughout IC23's ten clock periods. This creates or allows 60 cycles of 2400 Hz square waves, 0 to 5.4 V P-P, to occur at the base of Q1. Allowing for the one .6 V drop across Q1 from base to emitter, these 2400 Hz square waves become 0 V to 4.8 V P-P. Assume for a moment a 0 V to 6 V maximum output from Q1, and the 0 V to 4.8 V square wave would represent 80% of that figure; thus we will call position "0" the "white" level.

Without completely repeating all of this, going to position "1" on IC23 causes two less diodes in the IC23 to Q1 path. This means 1.2 V less maximum at the base, or 4.2 V. IC24, pin 3, causes another 60 cycles of 2400 Hz of 0 V to 4.2 V at the base, and 0 V to 3.6 V at Q1 emitter. This is 60% of 6 V or a "gray" shade.

For position "2", two less diodes, 0 V to 3.0 V Q1 base, and 0 V to 2.4 V Q1 emitter for a 40% "gray" shade. Position "3", two less diodes, 0 V to 1.8 V Q1 base, and 0 V to 1.2 V Q1 emitter for a 20% "gray" shade. Position "4", three less diodes (to be certain Q1 goes off), 0 V at Q1 base, Q1 off, 0 V and no 2400 Hz at Q1 emitter for a 0% black. Position "5" is the same as "3" by adding diodes back in. Position "6" is the same as "2", "7" the same as "1", and "8" the same as "0".

Position "9" is somewhat different to allow two features. One, it was desired to retain the same 12.5 ms wide sync as is present from the satellite, such that any time dependent circuits in the monitor would not see an artificially long (25 ms) sync signal. Two, since the period had to be divided in half to get the 12.5 ms sections, it was felt that the second half would be used for sync, thus causing it to occur just before the next horizontal line as in the satellite. Further, the first 12.5 ms section is made a 0% or black signal. This means presented on the screen will be 9½ bars going from white to black to white, and a half bar of black. This allows a bright white to align the left edge of the picture on the screen, and a good hard white to black transition at the right to check your amplifiers, beam switches, etc., for speed and absence of "ringing."

In order to accomplish this section "9" division into two 12.5 ms periods, simple gating is used. IC24 is a quad 2 input gate IC that has uncommitted collector transistors for outputs. While this is not really a requirement at outputs on pins 10 and 6, since they work into more TTL logic, it is necessary for the outputs on pin 3 and 11 for two reasons. The first is a TTL rule regarding the direct connection of two TTL device outputs having com-

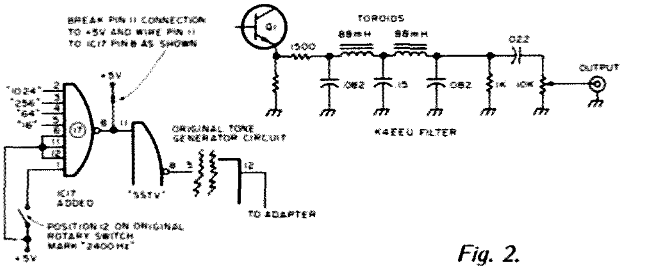

Fig. 2.

mitted outputs – a no-no! Secondly, and more importantly in this case, we want the base of Q1 to go all the way up to 6.6 V when not being acted on by IC23, or IC24 outputs pins 3 or 11.

Following the gating of IC24, the 40 Hz clock rate enters all the time on pin 4. This would cause 12.5 ms high and 12.5 ms low outputs at pin 6 if pin 5 were high, and a steady high at pin 6 when pin 5 is low. Pin 5 is tied to pin 10 of IC24. Pin 10 also ties to pin 13. By putting pins 8 and 9 together, the 8-9-10 gate is used as an inverter. The inputs 8-9 are wired to position "9" of IC23, and thus are high except when IC23 is in position "9". The low that occurs at pin 10 disables both the 4-5-6 and 11-12-13 gates of IC24 by holding at least one input low and, therefore, their outputs at a fixed high.

When position "9" is reached, it is the fall from high to low of the 40 Hz clock signal that causes this, and thus the low portion of the 40 Hz is on pin 4 of IC24. A low from position "9", inverted through the 8-9-10 gate to a high at pin 13 half enables the 11-12-13 gate. A low at pin 4 keeps pin 6 high and also pin 12 high, causing a low at pin 11. This low turns off Q1, and a 0% black is present for 12.5 ms. When the high part of the 40 Hz clock comes along and makes pin 4 high, then pins 6 and 12 go low and pin 11 now goes high. Since the base of Q1 is not held down during this 12.5 ms period by either gate 11-12-13 or IC23, only gate 1-2-3 affects it. As such, 30 cycles of 2400 Hz square waves at 0 V to 6.6 V P-P appear at Q1 base. This is then 0 V to 6.0 V at Q1 emitter, or 100%, namely "sync"!

You should see by now it takes longer to explain the adapter than to build it and get it running combined. Also, it may have occurred to you that any accurate 2400 Hz into the adapter will accomplish the same result. Quite true! I happened to build the WØLMD unit first; I have been having a ball finding out the many uses for it, so I used it here. It is great – and accurate – and it just was not worth the trouble of building another 2400 Hz source whose accuracy I could not trust as much (non-crystal source, etc.).

An SASE will get all the help I can give on the gray scale generator or the new timebase, but questions on the monitor or the articles contained in the references should go to the respective authors, since in those portions of my ground station I only copied their work and mine worked fine the first time. This way they are more apt to be familiar with any problems you are having than I would be. The generator I will take full responsibility for and will try to get you a rapid reply. ■

Note: While giving the unit adapter its final checks and preparing this article, some additions crept in, and are noted in Fig. 2. The output here is a square wave, as in my previous RTTY and SSTV adapters, and should be run through a like filter. The K4EEU filter used there works just fine and can be used here, so I include it in Fig. 2. Bert's filter appeared in Ham Radio, *July 1973, p. 6, for those who care to see its original use.*

An Automatic Thermostat

- - saves 10% on your fuel bill

It is common knowledge that heating bills can be reduced by setting the heat lower at night. As a matter of fact, most heating engineers will tell you that a savings of up to 16% can be realized by lowering the nighttime temperature in a home by 10 degrees Fahrenheit for at least 8 hours every day during the winter heating season. While it is very easy to use your index finger to push the thermostat back 10 degrees every night, this manual method does not turn out to be very reliable. Either someone forgets or the attitude of "I'm not getting up in the cold to turn up the heat" seems to prevail. Thus, the use of an automatic "day/night" type of thermostat is a better way to cut down on heat bills. This type of thermostat, however, is usually rather expensive ($50-75) and must be used in place of each thermostat in the house. In a dwelling with multiple zones and multiple thermostats, this can be quite expensive.

This article describes a "day/night" heating control which will automatically turn the heat down at night and back up again in the morning. While this device sounds like a "day/night" thermostat, it is different in that it connects to the 24 V ac electrical system of the furnace and will control all of the thermostats in a typical house. It is easy and economical to build and can be installed quite simply on either a hot water or hot air heating system. It has been designed so that an inexperienced experimenter can build, install, and maintain it.

Principles of Operation

A typical heating system has a circuit diagram similar to the diagrams in Figs. 2 and 3. Note that, in these diagrams, all thermostats have one side connected to a common point or common wire. The entire heating system (except for the control for hot water reservoir) is disabled if the connection between the 24 V ac transformer and this common point is broken. The "day/night" heating control has a 117 V ac relay connected to a cyclic timer. The "normally on" contacts of this relay are used to provide the connection between the transformer and the common point. At night, when it is time to set the heat back, the timer turns on the 117 V ac relay breaking the connection between the thermostats and the transformer disabling the heating system.

When I was building my first unit, I asked a neighbor who was a heating engineer if there was any reason why I should not let the house get as cold as possible during the night. His answer was a definite, "Yes, there's a very good reason." It turns out that a very complex relationship exists between the outside temperature, the day/night setback temperature differential, and the amount of fuel needed to bring the house up to temperature the next day. Because of this relationship, there is an optimum "setback" temperature, which for the average house is about 10 degrees for a maximum savings of 16%. If you exceed this setback temperature by very much, your savings will decline and it is possible to reach the point where you are ultimately using extra fuel rather than saving fuel. For this reason, an additional thermostat was included in the system to provide an overall nighttime temperature for the house. This additional thermostat uses the 24 V ac transformer on the furnace for power and is connected to a 24 V ac relay. This thermostat is set at a temperature which is 10 degrees less than the daytime temperature. When the house temperature falls below this nighttime setting, the thermostat closes, turning the 24 V ac relay on. Since the power leads for the 117 V ac relay go through the normally closed contacts of the 24 V ac relay, the 117 V ac relay will be inactivated and the system will go back to normal. At this point, all of the daytime thermostats take control and call for heat as required. When the temperature rises above the nighttime temperature, the heating system is once again disabled. Note that the nightime thermostat does not turn on all zones automatically but merely puts the heating system back to daytime or normal. This was done to

This project is a perfect opportunity to use your skills to make a few dollars on the side. This easily built thermostat can be sold to friends and neighbors and installed by you. — Ed.

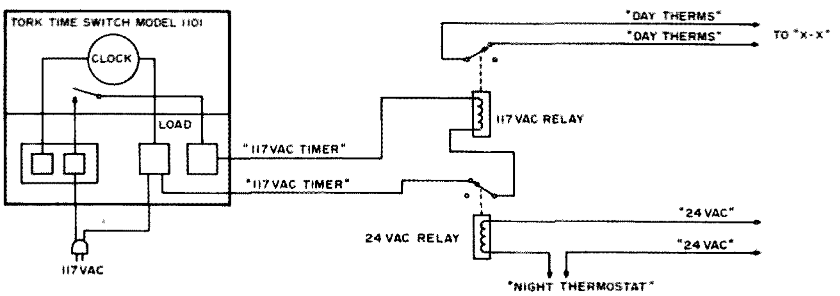

Fig. 1. Day/night furnace control.

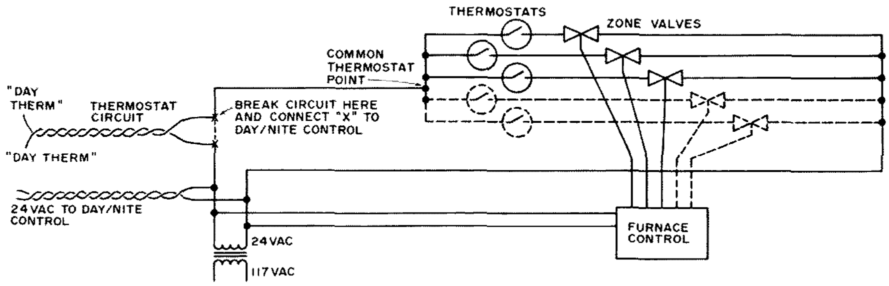

Fig. 2. Typical hot water heating system.

should be made with the appropriate circuits de-energized. Never work on a "live" circuit. When making connections to the 24 V ac transformer, be sure that the circuit to the furnace is turned off. In some cases, it may take two to three minutes for the heat to come on due to inherent delays in the controls for the furnace and the zone valves.

allow a given maximum temperature in a particular zone and to permit a zone to be turned off. If a zone is turned off during the day, it will not be activated at night by this system. I wanted this feature for my own house where the basement zone is off except for rare occasions. If I had used the nighttime thermostat to turn on all zones, I would be wasting heat in the basement.

Construction

Simple, quick construction was one of the design goals of the system since many neighbors expressed interest in this device and contemplated building it for their homes. Reliability was another goal, since few of the neighbors had an electronics background and thus could not troubleshoot the system should a malfunction occur. Consequently, parts were chosen on the basis of ease of construction and reliability, rather than on a minimum cost basis. Those readers with a good junk box and electronics knowledge can improvise and substitute, possibly saving a few dollars here and there.

I might mention that an all solid state version of this unit was built and tested; however, since it was not totally reliable and was expensive to build, it was abandoned. It is difficult to beat the relay in regard to reliability and cost.

A small metal box with dimensions of 3" x 4" x 5" or larger is used to hold the two relays. Top mounting sockets are used for the relays so that it will not be necessary to punch large holes in the box. A small quarter inch electric drill and a screwdriver are the only tools needed for the project. After assembling the unit, both the timer and the control unit are mounted on a wooden board which can be nailed to the cellar wall or any other convenient place. I originally mounted lights on the box, but since they have no real value and add unnecessarily to the cost of the unit, they were omitted in all subsequent units. Hence the circuit has no lights shown.

All connections made inside the box are brought out through a ½" grommet in a ½" hole. Connections should be labeled as shown in Fig. 1, using masking or adhesive tape.

The timer used is a heavy duty industrial timer and is very inexpensive for its quality. If you wish to cut corners, you may substitute the Sears #34H6442, which sells for about $7.00 in their catalogue.

Installation

Install the nighttime thermostat in a central part of the house. Do not mount the thermostat on an outside wall or a wall that gets cold. Use twisted pair, solid thermostat wire or equivalent for the run from the thermostat to the control.

After the control box and timer are mounted on the board, connect the timer and control together as shown. (If you use a timer other than the Tork timer, then connect the 117 V ac timer leads to the terminals marked "load" on the timer.) Plug the timer into an outlet and test the unit as follows: Throw the lever in the timer to "on" and the 117 V ac relay should pull in. Throw the lever to "off" and the relay should drop out. Unplug the timer, cut the wire going from the "common thermostat point" to the transformer, and connect the two ends to the control box leads marked "day therms." Turn on one of the thermostats in your house and the heat should go on. Leave the thermostat on, plug the timer in and turn the lever to "on." The heat should go off. Connect the leads marked "24 V ac" to the 24 V ac transformer and connect the "night therm" leads to your night thermostat. Turn the timer on so that the 117 V ac relay turns on. Turn the nighttime thermostat to ten degrees or so below the actual house temperature. The heat should stay off. Click the night thermostat on. The relays should click and the heat will go on. At this point the system is installed and ready for operation.

Note that all connections

Operation and Use

In our household, the timer is set so that the heat is turned off ½ hour before bedtime and turned on ½ hour before rising. With these settings, our house remains comfortable before going to bed and warms up before rising. In cases where we will be staying up late beyond normal bedtime, we merely turn the nighttime thermostat way up until it "clicks in." This puts the system back to normal without having to change the timer. In this case we turn the thermostat down before retiring and the nighttime system takes control.

It should be noted that when you set the trippers on your timer, the trippers are set to turn "the control on" and "the control off." This corresponds to disabling the thermostats and enabling the thermostats. In cases where no one is at home because of school or work, additional trippers may be added to turn the control on at 8:30 am and off at 4 pm or any other time. By doing this, the heating system would be in "nighttime" mode from 8:30 to 4. In this example, an additional fuel savings would occur for 7½ daytime hours.

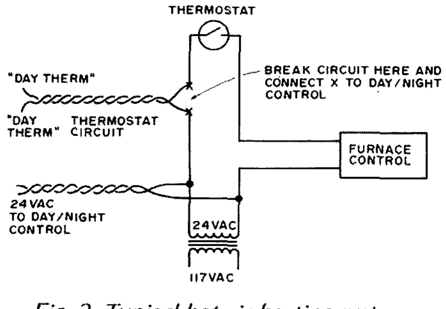

Fig. 3. Typical hot air heating system.

Recommended Parts List

Quantity	Description	Supplier	Approx. Cost
1	120 V ac relay Line Electric Co. Model MKH2A	Hatry's	$6.50

Notes to Parts List

Prices given may fluctuate, and do not include shipping and taxes.

The HI-G relays shown as alternates are very high quality hermetically sealed relays. They are recommended if you have means for cutting the two required 1-3/32" holes and don't mind doing a bit of metal work to get them mounted. Write to the manufacturer to get the address of the nearest distributor and the current price.

The Line Electric Co. relays are not hermetically sealed but do have a dust cover.

Distributor addresses: Hatry Electronics, 500 Ledyard St., Hartford CT 06114; Graybar Electric Co., Inc., 231 Newfield Ave., Hartford CT 06105; HI-G Incorporated, Spring St. and Route 75, Windsor Locks CT 06095.

Additional trippers cannot be added to the inexpensive timer noted in the parts list.

This system has been working for several years now and has saved us a real 10% in fuel utilization. We are quite pleased with the system; however, I will admit that it did take a while to get used to it. First of all, the bedroom does get cold at night, which means that we had to learn to sleep with three blankets and a quilt. Second, visiting the "head" in the middle of the night can be a chilling experience. Third, the temperature throughout the house at night is not as uniform as when the system is in normal. This is of little consequence since you should be asleep at this time.

Very obviously, the advantage of this system is fuel savings for the individual homeowner. It would not be unreasonable to save twice the cost of the unit during the first winter. From the savings that our family is seeing right now, we may do considerably better. Aside from the savings experienced in the individual household, this unit could have an impact on nationwide fuel economy if it were used on a national basis. It could help us conserve our scarce national fuel resources. ■

Mod for the Heath IO-102 Scope

- - faster warm-up

The Heath IO-102 scope kit appears to be one of the "better buys for the money." The 30 mV vertical sensitivity, 80 nanosecond rise time, and 5 MHz frequency response seem to fill the bill. Actually, the vertical response is adequate for viewing 15 MHz or higher signals with sufficient trace height to be usable. Assembly is on four main circuit boards: vertical, horizontal, sweep, and power supply. The finished unit is uncluttered, internal adjustments are no problem, and most components are easily serviced.

Critical power supply voltages are zener regulated, a fact which contributes to the operational stability after warm-up. The power transformer, which is double shielded, and circuit board layout result in a trace like those drawn in textbooks.

The initial alignment and internal adjustments, although not difficult, *must* be performed as directed. An accurate VOM or VTVM is the only equipment needed. During this alignment, one wishes he had a screwdriver with a ten to one drive. However, with a light touch, the desired results can be achieved.

Heath states that vertical drift during warm-up "for the first half hour or so" is to be expected. Experience with two of these units was as follows: From a cold start at 70° F, the trace was completely off the screen for the first ten minutes. After ten minutes, the trace appeared at the top of the CRT and drifted downward for 35 minutes, at which time it stabilized and no further drift was noted over several hours of operation. For someone who turns on the instrument and intends to use it all day, this may not appear as a problem. My use is on an intermittent basis and I found juggling the vertical position control inconvenient. The addition of four simple heat sinks produced two improvements:

1) A usable trace on the screen in 3 to 4 minutes.
2) A completely stable trace, without touching the position control, in 12 to 15 minutes.

Two heat sinks (Fig. 1) were made from 1/8 in. aluminum and attached to the vertical output transistor heat sink tabs as shown. The tops of these sinks, which were bent 90°, may be secured to the CRT shelf with standoff insulators or RTV cement. Two additional heat sinks, 1 in. by 1 in., were attached to the driver transistors with a small wrap-around wire.

Heath incorporates a 1 volt peak to peak calibrating signal at a front panel jack. I personally prefer a square wave calibrating signal and incorporated the circuit shown in Fig. 2. This calibrator provides a clipped sine wave signal of .1 V, 1 V, and 10 V. Three pin jacks were added next to the vertical input ground jack, to bring these signals to the front panel from the circuit which was mounted on the cover of the power supply transformer using existing screws.

All things considered, I feel you will find this instrument a worthwhile addition to your test bench and a pleasure to use. ■

I/O EDITORIAL

THE ALTAIR BUS

For some reason there has been a move recently to rename the Altair bus the S-100 bus. Dirty pool.

First, what is a bus? Well, we don't use bus structure much in amateur radio since we have very few common connections between the various modules of radio equipment, but the bus system has evolved for computers. A bus is a set of parallel wires to which the various modules of a system are connected. Most computers use a mother board with rows of connectors on it into which plug the boards which make up the system. All of the terminals on the connectors are connected to the same terminals on every other connector.

In the Altair, a 100 terminal connector is used, with 50 terminals on each side of the PC board. This set of wires carries power to each board, feeds in the signals and takes them out. To save on pin connections, many of the microprocessors use the same wires for feeding data into the chip as out, and this means it is possible to get by with fewer wires in the bus. Some of the bus wires carry handshake signals, etc.

While some hardware people rail out against the Altair bus, making much hay over this difficulty or that, it has become the de facto standard of the microcomputer world . . . partly because it was first . . . partly because its originator, MITS, sold more Altairs than everything else combined . . . and partly because, for all its faults, it is a very efficient and useful bus system . . . and it works.

The Altair bus is used by the Imsai and Polymorphic computers, plus a host of boards for ordinary and specialized functions. A recent estimate put the number of boards so far available for the Altair bus at 100. An even more recent (last week) count placed the number at over 150! I'm sure hoping for a series of articles describing all of the Altair bus compatible boards for publication in *Kilobaud* . . . writers please take note.

My reaction to the move to rename the bus the S-100 is that credit should be given where credit is due and it should be called the Altair bus.

ATLANTA JUNE 18-19

Pencil those dates in and make your reservations for one of the biggest and the best hamfest/computerfests in the country. Dayton is big, for sure, but other than the hamfest, what have you got? Atlanta is worth planning a couple days or so of vaction to correspond with the hamfest, for there are all sorts of fantastic things to do around there.

The 1977 Atlanta Hamfestival will be held at the Atlanta Marriott Hotel in downtown Atlanta . . . there are 1000 rooms available, more than twice what was available last year . . . and the rates will be $18 single and $24 double . . . free parking . . . big flea market area which is inside and air conditioned. Call 800-228-9290 toll free to make your hotel reservations . . . and better not wait too long.

There will be 120 exhibits, fantastic prizes, some of the top speakers in hamdom and computerdom (particularly featuring Ed Roberts, the president of MITS), and probably the best hamfest food you've ever tasted. Get a group together from your club and have a great time. How about a convoy with 2m intercom along the way?

The hamfest will be emphasized on Saturday and the computerfest emphasized on Sunday. This will be your chance to see the very latest in ham gear and meet the manufacturers and major dealers (Tufts Radio will be there again this year) . . . and to see what computers look like in the flesh, with a lot of computer exhibits. If you've been putting off messing with microcomputers, you'll be interested to see 'em in action . . . and get your hands on them to play some games . . . see 'em work RTTY . . . plot OSCAR passes, etc.

Last year I took a little time to see Underground Atlanta, ogle the incredible downtown hotels, and visit nearby Stone Mountain . . . a sort of entertainment and picnic center. There's a lot to see in the area . . . and do . . . and the restaurants . . . wow!

KILOBAUD

A high capacity data channel – *Kilobaud* – and the name of our new magazine, the first issue of which is now out. We were going to call it *Kilobyte*, but decided to duck a lot of legal expenses by changing the name slightly . . . rather spend the money on a better magazine than lawsuits.

The first issue runs 144 pages and is pretty good. It'll be better as we go – we're trying out some new ideas and after a while we'll settle down. Subscriptions are $15 a year – we'll start with the first issue while it lasts.

The hobby computer field is moving rapidly – new microcomputer chips are coming out faster than they can be put into systems. The most important newer chip is the Z-80, which is an advanced 8080A chip and may, despite my reservations about it, soon be the most used hobby computer system microprocessor.

The proliferation of TV games has opened many eyes. It started with one guy in his basement turning out Pong games and now it is sweeping the country, with many big manufacturers in there making hay. Not that Atari, the originator, is doing badly. The next step is one that you could make, if you wanted to. If you visit any of the arcades you'll see that the most popular games, by far, are games using a television screen and some simple controls . . . Tank . . . Red Baron . . . Quick Draw. These all use a Fairchild F8 microprocessor chip and the whole thing is done with a program . . . software! You see where I'm heading?

You have to have your own microcomputer going and build an inexpensive graphics generator . . . then write your own action games for it. When you're done, put the whole works onto one board and package it with the controls so it will play through a color TV set . . . and you'll have the world by the tail. If the public will buy ping pong, they'll go crazy over even better action games. Who's going to do it?

PUBLISHER'S DATA PROCESSING

We've been having a ball getting our own computer system going to handle the subscriptions and other jobs around *73*. We already have six CRT terminals going, trying to keep up with the new subscriptions to *73* and *Kilobaud*, and nine more on order for other data handling such as advertising records, bulk copy order records, inventory, repeater lists, club lists, dealer lists, accounts receivable and payable, billing for subscriptions, an article index, things like that.

Once we have all of the programs running smoothly, we'll be able to sell complete systems completely programmed for running a publishing house. The whole works will cost about as much to own as two office employees and will do the work of about ten or so. It should be popular. It should be about ready for a demo in the first quarter of 1977. If you know any publishers, give us a mention.

GROWTH AT 73

One of the reasons for those recent ads for more help at *73* was to keep up with our growth. You may have noticed that the last three issues have been over 200 pages – this takes a lot of work. In recent weeks we've increased the staff by 50%, doubled our typesetting facility, built a second photo darkroom, put in data processing stations on all four floors, doubled our computer capacity, and gone to two shifts in several departments.

We expect *73* to continue running over 200 pages (we're aiming at 500 pages per month), *Kilobaud* should increase from its present 144 pages to over 200 pages shortly, plus three or four good-sized books per month, a couple dozen newsletters, who knows what in computer program sales through the computer stores, and who knows how many complete computer systems for small publishers – it's quite a project for us to produce all this from our 200-year-old house in New Hampshire . . . but it's fun.

WHAT ARTICLES ARE NEEDED

If you are one of the pioneers of hamming or microcomputing, there are several reasons why you should stop every now and then and document your progress. First of all, there are a lot of fellows who would like to not have to reinvent the wheel. Give the other builders a break and let them know what you've done. Then there is the fact that being published makes you an "expert." You get a little less disrespect from fellow hobbyists. Probably of no interest to you is the payment for your article (we pay the highest, by far, in our fields).

The readers are most eager for any IC projects, digital articles, just about anything to do with computers . . . particularly as applied to amateur radio. Teachers in touch with Novice classes may have some good material to interest newcomers, activities of clubs might be helpful to other clubs, etc. Just about anything in small transmitters or receivers is of interest . . . some of these new ICs make fascinating projects possible.

Perhaps you're more into a book. If you have a book in mind, write up an outline plus a couple sample chapters and get in touch. Any one of a hundred outfits can print a book for you, but you need a publisher with distribution channels set up to sell your book . . . you don't make a lot on a book unless it sells well. There is a big need for well-written books on the fundamentals of all aspects of computers . . . and virtually nothing yet available. The day of self-teaching in this field has just arrived.

HAMFESTS AND COMPUTERFESTS

The two combo hamfest/computerfests that have been run so far have been successful enough to indicate that this is a good way to go. The two hobbies are remarkably parallel, with at least a 25% overlap both ways.

Computer exhibits at hamfests and

Go Forth and Multiply!

- - the space age approach

A simple 4 bit multiplication algorithm may be implemented on virtually any microprocessor system by simply placing a table of products in memory and then using the multiplier and multiplicand to form a relative address to point to the desired product in the table. This technique produces a fast multiply and does not require separate hardware in order to implement a multiply instruction. Furthermore, by using the fundamental properties of arithmetic, the 4 bit multiply may be expanded to produce an 8 bit or larger multiply instruction. The disadvantage of this fundamental technique is that a four bit multiplication table will require 256 eight bit memory locations.

The algorithms described in this article (both 4 and 8 bit) may be applied to systems lacking a software multiply or they may be used to replace a slower multiply in systems where a multiply instruction already exists.

As an example of multiplication in the binary system, consider multiplication of the two binary numbers 1001 and 1101:

```
Multiplicand ——►   1001    = 9₁₀
Multiplier ————►  x 1101   = 13₁₀
                   ----
                   1001
Partial     {     0000
Products    {    1001
            {   1001
                -------
Product ——————► 1110101    = 117₁₀
```

Multiplier | Multiplicand

4 BIT ADDRESS	4 BIT PRODUCT [contents of memory]
00 00	0000
00 01	0000
00 10	0000
00 11	0000
01 00	0000
01 01	0001
01 10	0010
01 11	0011
10 00	0000
10 01	0010
10 10	0100
10 11	0110
11 00	0000
11 01	0011
11 10	0110
11 11	1001

Fig. 1. Two bit multiplication table.

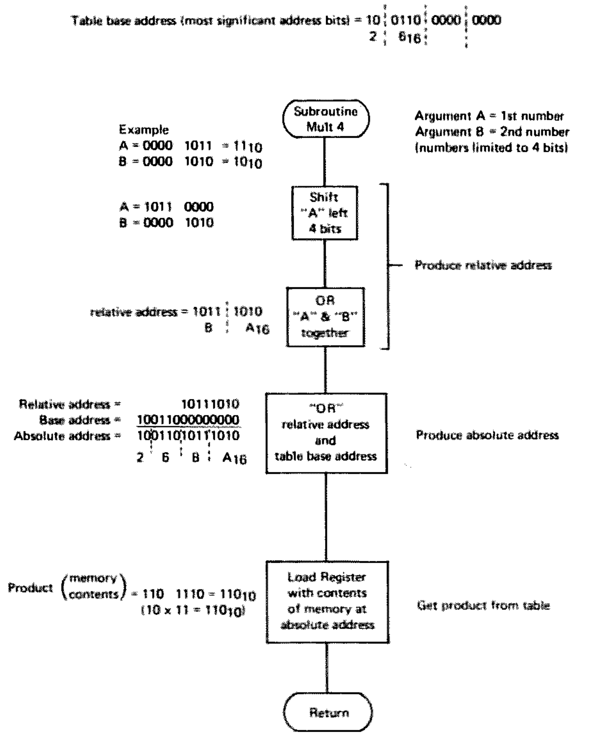

Fig. 2. Four bit multiply algorithm for 8 bit machine. Four bit multiplicand and multiplier must be placed into least significant bits of 8 bit word.

The Multiplication Table

The table of products, or multiplication table, is generated very simply by joining a 4 bit multiplier and a 4 bit multiplicand together to form an 8 bit relative address. The 8 bit relative address points to a memory location that contains the product, or result, of multiplying the 2 four bit numbers together.

As an example, consider the 2 bit multiplication table shown in Fig. 1. If we wished to multiply the binary integers 01 and 10 together, we would join the two numbers together to form a relative address of 0110 or 1001. The data contained at either of these relative addresses is 0010, which is the product of the two numbers (1 x 2 = 2).

Setting Up a 4 Bit Multiplication Table

The 4 bit multiplication table is easily set up by multiplying out each product using all combinations of 4 bit numbers. While this sounds time-consuming, it is not, and only involves 256 multiplications. (Some computer manuals may have this table already worked out.)

The multiplication table may be placed anywhere in memory; however, it is convenient to locate the table on a 256 word boundary (the start of a block of 256 words), so that either a logical operation or an arithmetic instruction may be used to generate the absolute address of the product.

Performing the Multiplication

In order to use the multiplication technique described, it is necessary to write a simple subroutine as shown in Fig. 2. In brief, this subroutine accepts 2 four bit numbers, uses them to form an 8 bit relative address, "ORs" in the base address of the table to form an absolute address, and then loads the product into a register from the table. A very minimal number of instructions are needed to perform the entire process.

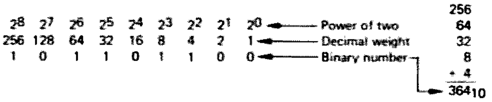

Fig. 3. Powers of two example.

An 8 Bit Multiply

Once the 4 bit multiply has been implemented, the basic properties of arithmetic may be used to generate an algorithm to multiply 2 eight bit or larger integers. To multiply the 2 eight bit numbers A and B together, it is first necessary to break the 8 bit numbers down into 4 bit pieces such that $A = m\ (2^4) + n$ and $B = q\ (2^4) + r$, where m and q are the most significant 4 bit portions of the numbers and n and r are the least significant 4 bit portions of the numbers. (See Fig. 3 for powers of two example, if you're in need of a little "refresh" in this area.)

Examples:

	m	n	
Multiplicand	1 1 0 0	0 1 0 1	$= 197_{10}$
Multiplier	0 1 1 1	0 0 1 0	$= 114_{10}$
	q	r	

$A = m\ (2^4) + n \longrightarrow A = 12\ (16) + 5 \quad = 197_{10}$

$B = q\ (2^4) + r \longrightarrow B = 7\ (16) + 2 \quad = 114_{10}$

$$\begin{array}{rr} & 197_{10} \\ & \times\ 114_{10} \\ \hline \text{Product} \rightarrow & 22458_{10} \end{array}$$

It then follows that:

$$A(B) = [m(2^4) + n]\ [q(2^4) + r]$$

Expanding the above expression produces:

$$A(B) = m(q)\ (2^8) + m(r)\ (2^4) + n\ (q)\ (2^4) + n\ (r)$$

We see that we can generate this multiplication by performing four bit multiplications, followed by a summation of the products. In the case when a power of 2 is associated with the product, the product must be shifted left n bits, where n is the power of two, prior to the summation. A simple subroutine to perform this 8 bit multiplication could be written as shown in Fig. 4.

Conclusion

The 4 bit multiplication algorithm given in this article may easily be implemented on any 8 bit (or larger) microprocessor system with very little difficulty, provided that the system has an 8 bit register in which to store the 8 bit product. The 8 bit multiplication algorithm, however, produces a 16 bit product, a product which is produced by summing four 16 bit product terms. For easy implementation of this algorithm, the microprocessor should have a 16 bit arithmetic register or a 16 bit software add.

The fundamental 4 bit multiplication algorithm described in this article was intended primarily to be implemented by software, such that the multiplication table would be loaded each time the system was loaded. There is no reason, however, why the multiplication table could not be placed in ROM or PROM and made a permanent part of the system.

The algorithms given in this article were not intended to be the last answer to the problem of providing a multiplication instruction for a microprocessor system. They are intended to provide a viable alternate solution to a problem which can be solved in many ways.

If the microprocessor user is running out of CPU cycles and his system is overloaded due to the use of such a software multiply or other software-implemented instructions, then the user should seriously consider adding additional hardware functions to replace these software routines. ■

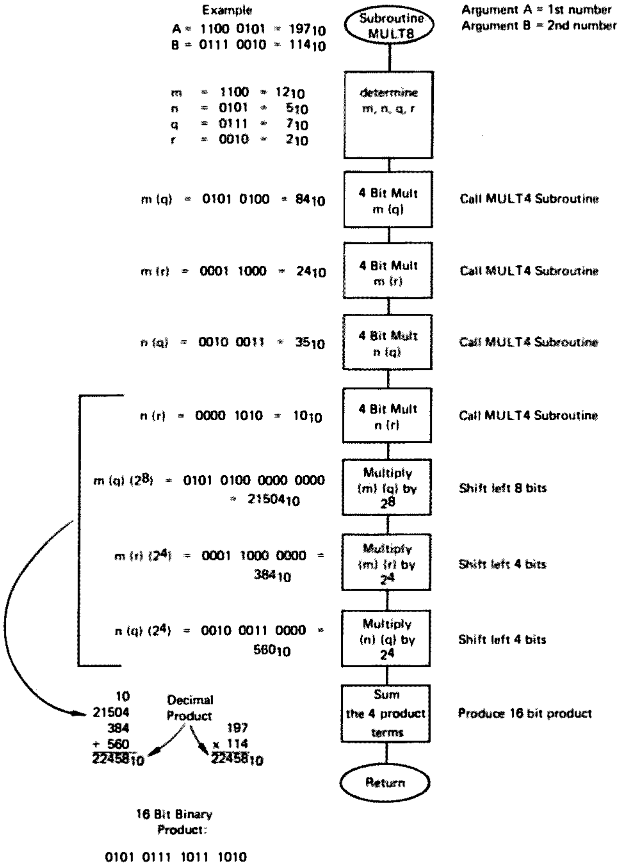

Fig. 4. Eight bit multiply routine (using 4 bit multiply subroutine).

I/O REPORT

by John Craig

Last month I squeezed in a quick mention of the Faire, and this month I'd like to fill in more of the details. Jim Warren (editor of *Dr. Dobb's Journal*) and Bob Reiling (editor of the Bay Area's Homebrew Computer Club *Newsletter*) are putting together a shindig on the West Coast in April. There are expected to be over 200 commercial and home brew exhibits, along with 100 formal and informal seminars, plus two big banquets.

You've all seen how microprocessors have played a big part in recent hamfests. Here's a "computerfest" that ham radio could play a big part in. One of the conference sessions is being planned around "Computers and Amateur Radio" and there's no reason why this couldn't be a good opportunity to get some computer enthusiasts interested in ham radio. We're going to have to show them what can be done when the two hobbies are combined, though.

If you'd be interested in presenting a talk on ham radio, the organizers would like to hear from you. If you've got your home system doing interesting things with (or without) your ham station, and you can cart it all to San Francisco, then you ought to see about getting a "home brewers" booth. (By the way, they are even offering nominal grants-in-aid to help with exhibit transportation costs. Check into it if you need to.) And, not incidentally, the "home brew" booths are free.

Don't get me wrong and get the impression that ham radio is the only thing you should consider (this just seemed like a good place to emphasize it). There are a multitude of other subjects you might be interested in, and I'll mention some of those next month.

The First West Coast Computer Faire, to be held in the San Francisco Civic Auditorium, April 15, 16, and 17, 1977. For further details call or write: Jim Warren, Faire Chairperson, Box 1579, Palo Alto CA 94302, (415) 851-7664 or 323-3111.

DEDICATED CONTROLLER APPLICATIONS

Almost without exception, every single board computer which has been manufactured and marketed was developed for the digital design engineer to use in dedicated controller applications (boards such as MOS Technology's KIM-1, Intel's SBC-80, National's IMP-16, etc.). For several reasons, I don't think it would be such a bad idea for some of the hardware-oriented hobbyists to start looking at the world around them through the eyes of those design engineers. In other words, start looking for the same applications they are.

Let me give you an idea of what I mean. I once heard an interesting story about a microcomputer engineer who had a neighbor who was in the asphalt business. During a conversation over the backyard fence one day, the road builder was relating to his engineer neighbor one of the problems of his business (which was costing him a lot of money). It seems that during the manufacturing of asphalt it is very important to get all moisture out of the sand/gravel mixture prior to beginning the mixing process. This is accomplished by using kerosene burners mounted under a large tumbler containing the sand/gravel mix. The problem was that these burners kept going, and consuming expensive amounts of kerosene, for some time after the mixture was completely dried out. The engineer recognized this as a problem which could be solved by a microcomputer, some sensors, and some valve controllers. He installed moisture sensors within the tumbler (and I'm still having trouble picturing that) and used the computer to monitor the amount of moisture and control the amount of kerosene going into the burners. And, of course, the burners were turned off at precisely the right time, resulting in significant savings in kerosene. As a matter of fact, the designer derived his "fee" from a royalty based on a percentage of the annual savings the new system offered (compared to the old way of doing it).

We've got a couple of things going for us in this area . . . and a couple against us. First of all (in the "against" department), we all need more exposure to the world of analog-to-digital and digital-to-analog conversion techniques. We haven't seen enough articles on the subject (in any magazine) and it's doubtful that there are a great number of people among our ranks with extensive experience in this area. Those that are should get busy and share some of their knowledge through an article or two. I would think a good place to start would be a publication such as National Semiconductor's *TRANSDUCERS Handbook*. (The handbook covers temperature and pressure transducers and application.)

On the plus side, most of the hams who are into computers have sufficient electronics background to pick up the necessary information on A/D and D/A applications and the interfacing to a computer. Also, we're going to be seeing articles on some *very* low cost single board computers in upcoming pages of *73* and *Kilobaud*. Some of these boards can be built for as little as $50 to $100 (quite an improvement over the $250 to $450 range we're normally faced with from the commercial versions). And, one more plus . . . the hobbyist isn't going to have to go through the "trauma" of having to learn how to program his microprocessor. He's already been there!

QUANTITY PURCHASING

A friend of mine is building a low cost 132 column line printer which should have quite an effect on the hobbyist and small business computer market. Just like anyone else attempting a project such as this, he's having his problems getting financial backing for the venture. In the process of putting together a cost analysis package (to show to prospective backers), he ran across some interesting things which are worth sharing with you.

One of his objectives in putting together this package was to itemize each component that goes into the printer and put down the single quantity price, the quantity price (100), and the total cost per unit for that component (based on the number required for each unit). After getting all this information down, he could then very easily add it all up and come up with a cost-per-unit based upon single quantity purchasing versus quantity buying (he knew that one was going to be quite a bit less . . . he just wanted to see how much).

He quite naturally assumed (as did I) that the best way to go about getting the lowest prices for the various components would be through OEM price lists. We were both in for a surprise. Here's an example of what he came up with on integrated circuit prices using a Signetics and National Semiconductor OEM price list:

	1 to 24	100 to 999
Signetics – 7400 DIP	$.51	$.34
National – 7400 DIP	.55	.35
Signetics – 7474 DIP	$.78	$.52
National – 7474 DIP	.88	.54

The above information certainly doesn't contain any earth-shattering news (except to show my friend the slight price difference between the two). But . . . and look out, here comes the good part . . . after getting the whole package together he happened to glance at the James and Godbout ads in *73* and suddenly discovered what low prices really are! Here's the way they stack up with regard to the two ICs picked at random:

Godbout – 7474 DIP	.36
James – 7474 DIP	.32
Godbout – 7400 DIP	$.18
James – 7400 DIP	.16

And those are single quantity prices!! Rather incredible, right? Well, you ain't seen nothin' yet! Both Godbout and James offer a *20%* discount on orders of 100 or more!

Normally I'm pretty level-headed and don't get too excited about such things, but this really intrigued me. Furthermore, it occurred to me that a lot of other people out there in hobbyville and small businessland might make the same mistake (using OEM price lists) when getting ready to manufacture things. Therefore, I decided to do some checking into the situation and find out just what was going on. A phone call to Bill Godbout cleared it all up. Very simply, if you're going to be buying ICs in the hundreds of thousands, such as Godbout and James do, then the manufacturer brings out an entirely different price list than the one my friend had. But the most important point he brought out is that the chips he and James (and most of the other large volume dealers) are selling are full-spec ICs. Your first impression after seeing the large difference in those prices is that the dealers must be selling something other than quality material. Not so.

MISCELLANEOUS

About a year ago I subscribed to *Ham Radio* and *QST* for the express purpose of keeping track of the "competition" and their coverage of the computer hobbyist/microcomputer applications area. Each month when those magazines arrived it became more and more obvious that I had wasted my money. But, I hate to just throw them away . . . after all, there's very likely somebody, somewhere, who would like to have them. I think perhaps they'll be going with me to the next ham swap.

Quite often I have people ask me about the opportunities for getting into computer programming and/or maintenance through the experience they've gained "working" with a hobby system. I wouldn't want to discourage anyone, but I think such an approach would depend an awful lot on the individual and his plan of attack. The idea is not too terribly farfetched, though. I glance through the Sunday *Los Angeles Times* classifieds every now and then to keep track of anything that might have a bearing on the computer hobbyist field. It's interesting to note that I've been seeing more and more ads for microcomputer-experienced personnel. By "more and more," I mean 4, 5, or 6 each Sunday . . . compared to none a year and a half ago.

Table 1. The improved memory diagnostic program. Note that the programmer must initialize "TWP", "FWP", and "NB" according to the block memory he wishes to test.

Dan Stogdill VE3DWC
182 Victoria Street
St. Marys, Ontario
Canada N0M 2V0

In a recent article (*73 Magazine*, Oct., 1976, p. 114), I described a simple memory diagnostic program for 8080-based systems and illustrated its use in troubleshooting 4K memory boards. While that method is effective for localizing gross defects, such as chips which have one or more bits permanently set, more subtle defects may evade detection. For example, after discovering 4 bad chips in 8K of memory, by the simple techniques described in my previous article, I attempted to load and run "SCELBAL" – but to no avail. After many hours of checking and reloading scattered addresses with the correct contents, it dawned on me that when I corrected the contents of some addresses I was sometimes changing the contents of other addresses. What obviously was needed was a more thorough memory "debugging" approach. This article, I believe, brings us one step closer to that end, and "SCELBAL" is now running fine.

The simple methods which I outlined in the previous article employ two basic techniques. One technique takes the value of an address and loads it as a data word into that same address. This is done for all 256 addresses on a page. Next, the values of the addresses are compared with their respective contents. If they are dissimilar, an error printout is produced. For example, if the eighth data bit (bit 7) at address 023 is always set to 1 due to a chip defect, the actual contents of that address will be 223, which would generate an error. However, if bit 0 of address 023 was always set to 1, no error would be detected. Needless to say, this would cause problems in an actual program which required that bit 0 at address 023 be set to 0.

One way that the above problem can be overcome is to use a slightly different approach. Typically, this second technique loads a random number into all ¼K addresses of a page and then sequentially examines the contents of the 256 addresses to see if they still contain the pattern which was loaded into them. If enough random patterns are tried, a bit at some given address which is permanently set will sooner or later be discovered. However, a not uncommon problem is for 2 or more addresses to interact. If addresses 023 and 025 were interacting in such a manner that whatever was loaded into bit 7 at address 025 changed the corresponding bit in address 023, then this second technique would not detect the error by virtue of the fact that the whole page was loaded with the identical data word.

As if the above wasn't trouble enough, programs which check only one page of 256 addresses at a time are unable to detect interactions between 2 or more of the 4 blocks of 256 bits which actually reside on a single 2102 type memory chip.

The program described in this article overcomes the shortcomings listed above,

and when fully implemented provides a potent tool for detecting memory problems. In order to make maximum use of the procedure, I recommend that you read my earlier article in order to understand the functional layout of a typical 4K board of 2102 chips.

About the Program

In my system, the program, which is listed in Table 1, resides on page 043, address 200-320 (octal). Relocation should provide little difficulty once the mechanics of the program are understood.

The program loads a Test Word (TW), either 377 or 000 (octal), into one address in a 1K segment of the board. It then fills the remaining addresses of the 4 pages with a Field Word (FW), either 000 or 377 (the complement of the TW). When the 4 pages have been filled with the FW, the program retrieves the TW which was previously stored in memory and examines it to see if it was altered. If the TW has been altered, an error printout will be produced. If no error has occurred at that address, the next sequential address is loaded with the TW while all other addresses are loaded with the FW. Then the stored TW is once again tested. This process is repeated until each address in the 4 page block has been tested.

The program repeats the above procedure eight times (your option). The reason for repeatedly testing a 4 page block is that the repeated accessing of a particular area in memory will generate additional heat, consequently increasing the chance that marginal chips with thermal defects will be detected.

The programmer then sets up the program to check the next block of 4 pages on a board, until the whole board has been checked. In order to keep the program simple for beginners like myself, I opted to have the programmer initialize each successive 4 page block; obviously the computer could be made to do it, albeit at the cost of making the program more complex and harder to follow. After checking out the whole board, the programmer should change the TW and FW to the values given in brackets in the program, and then test the whole board again. You may encounter a situation where the 377 test word won't be altered by an interaction with a 000 field word, but a 000 TW will be altered by a 377 FW.

020 167 375	020 134 010
020 222 376	020 135 020
021 026 177	023 163 100
022 140 337	023 272 004

Table 2. A typical printout from "DEBUG." Test word for the left-hand column was 377, while the test word for the right-hand column was 000.

Table 2 illustrates a typical printout. Note that the page, address, and incorrect data are outputted. As in the previous program, this program assumes the existence of an octal conversion and print routine ("OCTOUT") which it can call.

A Few Tips

When you are making the test, do it once or twice with the case off the computer when it is relatively cool. Then put the case on and run through the procedure with the computer thoroughly warmed up. I found 4 defective chips with the program when testing cool, and 4 more when testing hot. What really blew my mind was that two of the cool defects showed up only sporadically under the hot condition. Also, this is a time when effective use can be made of the spray-type component coolers. You might also wish to sandwich the memory board(s) between other boards in order to entrap the heat.

I hope you find the present techniques as valuable as I have. Happy troubleshooting. ■

A Super Log

-- a program for the ham shack computer

Most software articles I'm finding in all the popular magazines are written in software language, which I have a heck of a time understanding. I'm just a radio amateur, not a computer genius. So it takes a little more detailed explanation for me to understand what's going on. However, I have a little business of my own and to help my business I purchased a SWTPC 6800 computer kit. Once I got the machine together, I was most anxious to put it to work for my business. And that's where I gained a little software knowledge. After writing the program for my business, I thought it would be interesting to present the same program, with a few changes, to my fellow hams. So, here it is.

The object of this article is to give you a logkeeping program and to explain how the program works. You may not have a 6800 microprocessor yourself or may want to develop the program for your IMSAI or MITS computer. Or, you may not even have a computer and perhaps just want to know more about software. If you have a Motorola 6800 microprocessor and you are a radio amateur, the program listing at the end of the article is for you. This program does a few unique things and can be modified just like an electronic circuit to best suit your personal needs. First of all, we'll spend some time talking about the basic concept of the computer program and what it is supposed to do so you can have a little better understanding of what's going on. Then we'll talk about the details of the Amateur Computerized Logkeeping Program.

Before we jump right into the meat of the article, I should tell you a few things about the program and how it operates and exactly what it can do for you. To begin with, it's a *Search* program. It will search for data entered in memory, by using the first three characters entered. It's not an alphabetic search; it simply uses the first three characters, which can be alpha, numeric, or anything you want. This is a natural for amateur radio calls since the *last* three letters of any callsign are different for each amateur station. (While indeed it is possible to have a WA7SCB, a K7SCB, a K6SCB, etc., odds are against working a bunch of hams with the same last three letters.) A typical input to the computer might be that shown in the photos. Note the call letters start on one line and the state begins on the other. Thus, the computer can search for the call letters, or the state, or for whatever is on one line. There are also some entry and change programs that allow you to delete entire lines of data, thus removing someone from the logkeeping memory. If your computer has a cassette interface, there is a program to store logs on digital cassettes and read them out on a later date if you need to, to produce hard copy on a teletype or line printer.

The only character that can be accessed directly by the keyboard without punching another button is S. S is the key that tells the program to go into the search routine. The computer will come back with CALL? You then insert the last three letters of the call followed by a period. The period causes the program to start running and the computer searches through memory. Any time your processor comes to a line of information that starts with the three letters that you punched in, it will print them on the screen of the CRT. You then can ask for any other listings that start with those three letters by pushing any other character on the keyboard (preferably line feed — makes for a neater display). Or, you may go back to the main program by punching a Y, telling the computer, "Yes, this is the guy I was looking for." You may *Enter* data by holding down the control button and then punching the letter E. If no more memory positions are available, the computer will come back with FULL (not all of us can afford 64K); if there are memory positions available the com-

```
LOAD ACCUMULATOR "A" (IN HEX)

        LDA A:

            IMMEDIATE - 86 XX (XX is data)
            DIRECT - 96 XX (XX is address 00 XX)
            INDEXED - A6 XX (XX is amount of offset from "index" contents)
            EXTENDED - B6 XX XX (XXXX is full address)
```

Fig. 1. 6800 addressing methods, using "Load Accumulator A" instruction as an example.

The WA7SCB station.

puter will respond with CALL? You then enter the data that you wish to be stored, formatting it as shown in Table 1. (Of course, you may use your own format, but you do need to standardize. This way you'll be able to search for the data again at some later date.) After you have entered all the desired data, press the period. The period then terminates the Enter Routine and the computer sends "*73s". Those of you who do not go along with saying "73s" in its plural form simply change the program to say "73" or "blank" or "thanks" or whatever you want.

The third mode the computer operates in is *Change.* When you push control C, the computer comes back with CALL? You then enter the first three letters and hit a period. The computer searches for the data, then prints out a line of data on the screen. If the line shown is not the one you wish to change, just push line feed, and the computer will search for the next entry in your computerized log that has the same first three letters. As soon as you come to the call letter that is the one that you wish to change, depress Y which activates the CALL? response. Now you can re-enter data. To delete the entry, all you do is enter a space and a period. This is because in the Enter Routine the computer is searching for spaces in memory. If it finds anything but a space at the beginning of a line, it assumes that there is some valid data there and goes to the next line of data in memory. Thus, inserting a space as the first character in a line of data in memory will delete the entire line of data. The next time you use the Enter Routine, the computer will find that space, and your new data will write over the old line in memory.

Obviously, if the computer is looking for spaces in memory, the first thing that we have to do is to stuff spaces in memory. We have a program to do that and it is called *Load Up* (with spaces) routine. You have enough open memory positions to store as much data as your configuration is capable of handling. Of course, you could just put a space in every 32nd character (the beginning of a line in memory).

Any time a wrong character is punched on the keyboard, the computer says "GOOF!" It can say anything else you'd like it to say, but GOOF was convenient and doesn't take much memory.

Programming – General

As I said, I am a radio amateur and not really a computer programmer. In order to make my computer work, I had to first learn what was going on inside. It's simple enough to understand. There are three basic parts to a computer: the I/O, the processor, and the memory. The function of the I/O is pretty simple. It's a way to input and output data from your computer. The function of memory is simple too. It remembers. That's all there is to it! It's the microprocessor that's tricky. The microprocessor is a collection of registers, decoders, timing circuits, and whatever else it takes to perform the functions of decoding information from memory. The microprocessor is a programmable AND gate, OR gate, Adder, Subtractor, Shift Register, etc.

A typical microprocessor has several registers inside it. These registers are used for temporary data storage, manipulating data, shifting bits around timing, decoding, etc. The 6800 is a typical microprocessor with several registers. It has two registers called accumulators (the A accumulator and the B accumulator), which are nothing more than 8-bit data registers. A hexadecimal B6 is the com-

mand to "load Accumulator A." It's called *Load Accumulator A Extended* because it tells the microprocessor there is an address to follow. The 6800 also has some other modes of operation; for example, it's possible to load the A Accumulator from an address specified in another register in the 6800. The other register is called the *Index Register*. The command *Load Accumulator A Indexed* can also contain offset so that you may either add or subtract from the number that is the index register for your memory address. Another mode of loading the accumulator with data is the direct mode. The direct mode is limited because it is only a 2-bit address. Thus, the highest number you can specify is address FF, which amounts to 265 memory positions. There's still another mode of loading the accumulator, the immediate mode. In the immediate mode, the accumulator is loaded with whatever data is in the location "immediately" following the instruction. The accumulator is told to be loaded and then is given a number to be loaded with. Fig. 1 shows the modes of putting data in the accumulator.

Mnemonics are aids to help us remember things. It's pretty tough to remember C6, A6 or B6 but fairly easy to remember Load Accumulator A, or its mnemonic, LDA A. If a person has an *assembler*, a program can be generated using just these mnemonics (i.e., no hexadecimal or octal numbers punched in at all). Typing in STA B SWER would result in storing the B accumulator in a location which has a symbolic name of SWER (somewhere). In our machine-language coding the mnemonics simply serve as memory aids for the instructions (and symbolic names for addresses are not used).

Without some way to talk to it, the computer is a pretty useless device. The read only memory in the SWTP 6800 computer is nifty because the first thing that happens when power is applied is that a Power Up Routine is executed and the computer prints an asterisk (a *prompt* character) on the screen of the CRT or teletype. The SWTP computer then recognizes the commands L, M, P and G. The M command (modify) allows the loading of programs into memory. With the L command you may load the programs from a punched tape, and the P command will cause paper tapes to be punched. The G command starts a program that has been loaded into the computer. The G command makes the computer begin at whatever step has been designated as the beginning step for your particular computer program.

Front view of the home brew terminal.

The Ham Computerized Log: A Blow by Blow Description

The program is written in sections. The first piece is the main routine. This routine is responsible for recognizing various command characters entered at the keyboard. Those are S, Control E and Control C. Any other character entry will get an error message (GOOF!). Other programs include the Enter Routine, which starts at a certain point in memory (specified by you), then checks that point, and every 32 characters beyond, for a space (hexadecimal 20). When it finds a space, it requests your input of data which will then be written on that 32 character line of memory. If the enter program searches beyond your specified memory point and cannot find a space, it concludes memory is full and sends you a "FULL" message.

The Search Routine takes your keyboard entry of three characters and then searches through memory on a bit-by-bit basis beginning at character position 0 and checking every 32 characters thereafter. It will look for the first character that you typed in at character position 0, 32, 64, etc. As soon as the routine finds a match, it skips to the next character and checks that for a match. If there is no match, the routine proceeds to the next 32 character set. If it finds a match it checks the third character and if this matches also, the program assumes this is the correct character combination and prints the entire message.

The Change Program is entered by pressing control C. It does everything the Search Program does except that it jumps back into the Enter Routine once it finds the correct line. You can enter

```
INITIALLY:
     M    A048   ENT SP 00
          A049   ENT SP 0D
          A04A   ENT SP CR
     Press G -computer says "G".
     Press Y -computer says "GOOF!"
     If all is well, computer will checkout OK and is ready to use.

TO USE

    TO ENTER A NAME:
          Press E-computer says "CALL?"
          Type in name-first three letters duplicate, others okay
          to abbreviate.
          At end of entry, hit the period.
          Computer says "*73s."
    TO FIND A NAME:
          Hit S, computer says "CALL?"
          Enter name or first three letters, then a period.
          Computer searches and prints.
               A. If name is correct, hit Y.
               B. If name is wrong, hit SP.
    TO CHANGE AN ENTRY
          First search to insure it's there
          If OK, hit C, computer says "CALL?"
               Enter first three, then a period.
               Enter "Y" or SP.
          Computer gives new name or prints "CALL?"
               Enter changes (delete by SP then hit period)
               Computer says "*7 ."

the new data, changing whatever data is in the 32 character line of memory.

There are two main subroutines. One is the Search Character Subroutine (this is used by the change program and the search program). The Search Character Subroutine looks for a particular character until it finds a match in memory, then holds the memory location in the index register.

The other is the Outline Subroutine. This one is used in conjunction with a temporary memory position to output various messages to the operator. Once your messages have been entered in a given place in memory, the Outline Subroutine will print them on the screen whenever you call for them.

Terminators for all the routines are periods. When the computer sees a period it will know that is the end of an entry or that it is the end of a line of memory.

Quirks, Problems and General Points of Interest

Let's go to the beginning. The main routine is located at 0000 and goes through 001F. If you are an SWTP purist who is obeying the manual's suggestions, you may want to put the main routine somewhere else. The SWTP books suggest you leave locations 0000-0020 open for future floppy disc interface. It's easy to move the main routine. Also, you may not like the computer recognizing S, CTL

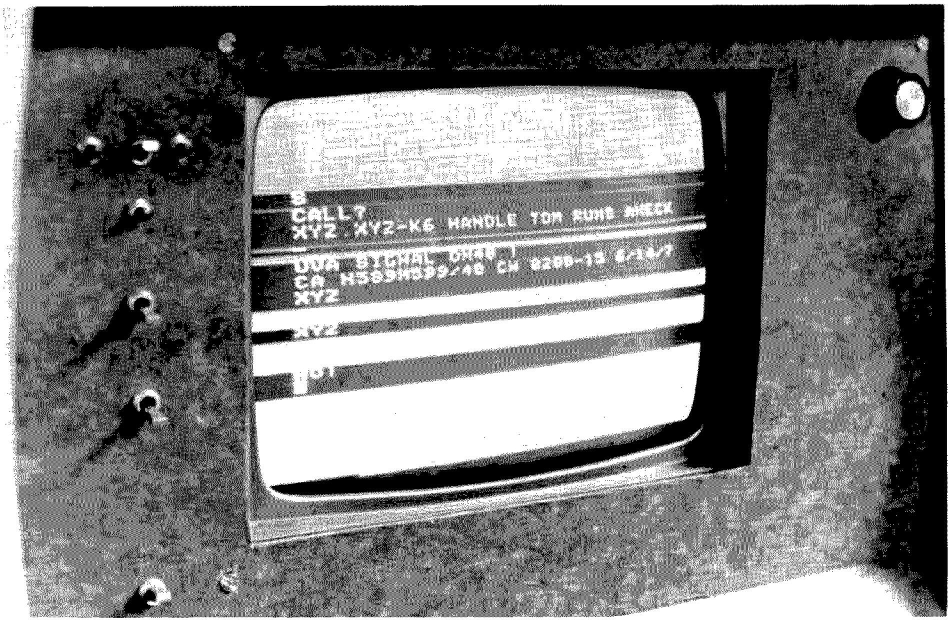
E, and period, so you can use whatever codes you wish (see 0004, 08 and 0E). Note that 001E contains the starting memory location. Should you decide to store your log info in some other part of memory (maybe the last 4K, or so), you mustn't forget to change this address.

The enter program at 0020 looks for spaces to find an empty spot. You don't need to use spaces; it's just that I liked 'em. You can put just about anything in 0024. Note, too, I went to a little subroutine at A050 in the middle of my program. I added these steps after the entire program was written and wouldn't work. You could put these steps right in the program, or at some other location.

Also, location 0059 loads accumulator B with the most significant bytes of the last memory location you are using (mine was 0FFF until I recently added memory). Don't forget to make 005A fit your system.

Here is an interesting point concerning the EDIT Routine (0075). With this jewel you *have* to change something. That's why you should search to make sure what you want to change is really in the computer, because if the computer says "NO!" in EDIT Routine, it means there are no more lines of data starting with the characters you entered. The problem is that you will then be writing over the message that says



Searching for a call in memory.

Searching by state, and then retrieving information on a station worked in that state.

"NO." Don't panic when this happens. Just type "LF/CR/NO!." The period will terminate the edit routine and eliminate this problem. This will probably only happen once; after that you'll learn to search before you change!

The search routine starts at 00CA. It is pretty straightforward. An interesting point is that it has an upper memory limit, too. This is the address of the highest memory position you want to search for. My upper address is 0FFF (add one = 0100). So, the most significant byte 01 is put in the Search Routine at 0028.

Finally, one last point: In the Miscellaneous section, note the memory storage allocations. Temporary data (the three characters you want to search for) are located at 0140 through 014F, and all fixed messages start at 0150. Normally this causes no problems, but if some overzealous person gets to your computer and decides to figure it out alone, he or she may type in over 16 characters instead of the three needed, probably figuring the computer will find it faster that way. Of course when 16 characters are exceeded, the entries will start writing over all your nifty messages. If you find some rather weird messages coming out of your machine, check and see — chances are your friend wrote the Gettysburg Address for you . . . all over your program! ■

I/O EDITORIAL

from page 72

conventions have been drawing the biggest crowds, so we know that a large percentage of hams are definitely interested in computers. The articles in the *73* I/O section reflect this interest and have helped develop it. Computer firms exhibiting at hamfests have been most enthusiastic about the response . . . and the sales of equipment.

Not as much is known about ham exhibits at computerfests, but there is a marked increase in getting ham licenses by computer hobbyists. They are well aware that a great many of the recent applications for computers have been in ham-oriented applications . . . and they are greatly enthused over the prospects of being able to interface their system with another over the air. You'll see a lot of this happening as more and more repeater systems get geared up for this.

Computerfests and hamfests pull about the same size crowds since there are about as many computer hobbyists as amateurs in the country. But, while amateur radio is growing at about 11%, computerists are growing at about 100% per year . . . it may turn out that a major source of new hams will be via the computer hobby instead of CB. All the more reason to tie hamfests and computerfests together.

If your club is figuring on a hamfest, you could do worse than get our package of information on the hobby computer field . . . it's $50 and you get a list of about 300 hobby computer clubs, over 500 manufacturers and dealers (for prizes and exhibit booth sales), newsletter publishers and magazine editors. You'll also get instructions on how to get PR in this field. The list is on gummed labels, ready to use.

If you have anything big planned, you might call me and see if we can coordinate. I might be able to help set up your speaking program with top computer talent and even help sell a few booths, too. There is only so much of me to go around, so it's got to be good-sized.

Short On Memory?

- - build this 2K board for your 6800

John W. Molnar WB2ZCF
Box 561
Ridgefield NJ 07657

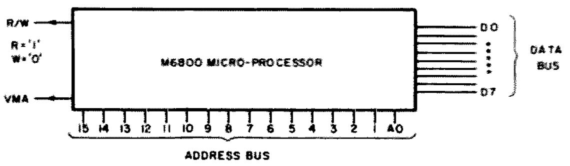


Fig. 1. M6800 control lines used by the memory interface. Read/write line (R/W) controls flow of data on 8 bit bidirectional data bus. The valid memory address line (VMA), when HI, allows the interface to respond to the 16 bit address on the address bus. Each address line, when HI, represents a power of two in the binary numbering system. For example, if lines A0, A2, and A10 are HI, the address sent to the interface is equal to $(2^0 = 1 + 2^2 = 4 + 2^{10} = 1024)$ *or* 1029_{10}.

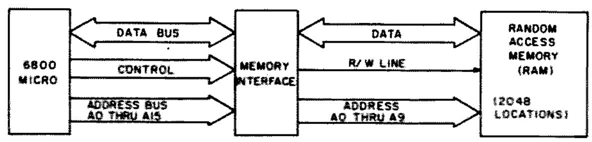

Fig. 2. Information flow between micro, interface and memory. Note that only address lines A0-A9 go to memory, as the interface uses remaining lines to decode valid memory addresses.

Medical science tells us that only a tiny fraction of the human brain's capacity is used during an individual's lifetime. This excess memory capacity is unfortunately not a feature of the average home microcomputer system, a fact which usually causes the experimenter to seek additional "brain power" almost as soon as the new micro kit or prototype is finished and running. Most of the commercially supplied micro kits provide only minimum memory, usually 1024 bytes (1K) or less. It is in this memory that the user's application programs and language processors (such as BASIC) must reside.

A typical amateur radio application for a microprocessor system is the control of a RTTY station. The micro can be programmed to send CQs, answer calls automatically, detect speed changes, etc. However, it becomes immediately obvious to the operator of the station that more memory than is supplied with most micro kits is required to handle even the simplest functions, such as sending a list of station equipment. For example, the single message:

CQ CQ FROM WB2ZCF – "JOHN"

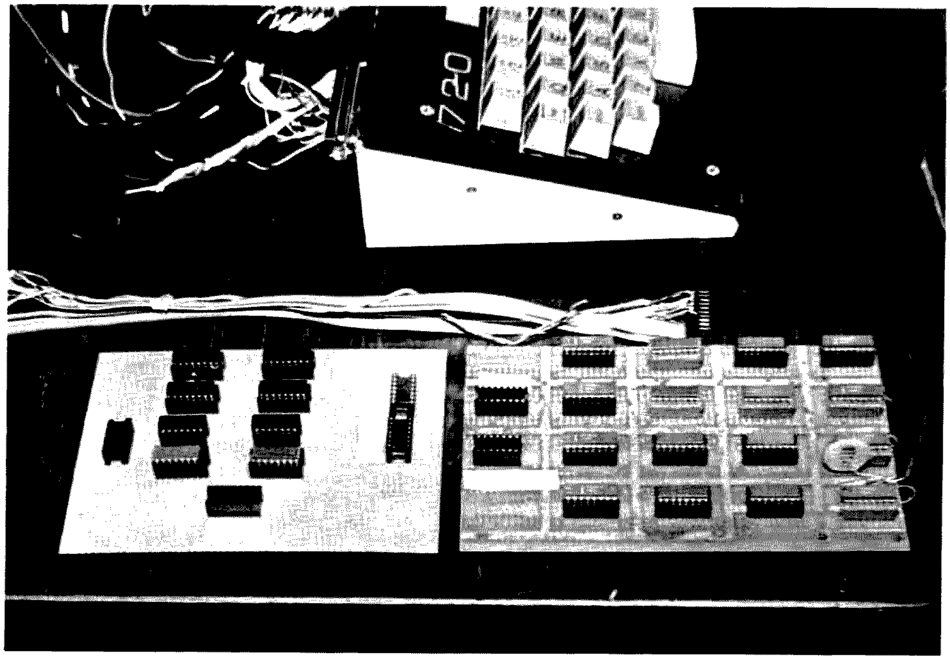
takes about 33 characters, including shift functions. Taking into account that the machine code to control the system occupies the same memory, it becomes obvious that, when stored in memory, even a short list of equipment, when added to other operator comments, rapidly eats up critical space. Think about some of those other functions that can be controlled by a micro, and you will be ready to consider adding memory capacity to your micro system. There are two ways of making your micro smarter – buying a commercial 2K or 4K board and sliding it into your system or, in the best ham tradition, home brewing a memory system for your setup.

This article describes the latter approach – a complete do-it-yourself 2K memory system for a Motorola 6800 type microprocessor, including interface and memory board. The design uses popular (and inexpensive) 2102 static memory chips, and the interface design may be modified to support other microprocessors. All parts used in this project are readily available from *73* advertisers.[1] I have attempted to present in logical order the background required to understand the project, the design criteria, pitfalls, actual construction and logic analysis, and, finally, the debug techniques used in bringing up the add-on memory. Hopefully, this will encourage those of you who need additional memory for your systems to consider building it yourselves.

The Background – or, the Microprocessor's Nervous System

The Motorola M6800 microprocessor is capable of

supporting up to 65,536* bytes of random access memory. The single byte accessed during a machine cycle is selected by 16 address lines. Each address line may be viewed as a digit (1 or 0) in the binary system; therefore, the unique memory address generated by the micro is really a binary number in the range of 0-65,535 (see Fig. 1). The data to be read or written by the micro is transferred over eight data lines, or the data bus. The memory is directed to read or write by a single line, the R/W line. If the 6800 places a 1 (TTL HI) on the R/W line, the memory sends the single byte of data (whose address was presented on the 16 line address bus) to the micro over the data bus. A 0 on the R/W line causes a memory write to occur; the data on the data bus is written into memory. One control line, called VMA (Valid Memory Address), is a 1 if the micro really wants to access memory. These lines, the address, data bus, R/W, and VMA, must be used to coordinate data flow between the micro and our planned add-on memory. The logic required to do this is called an *interface*. We will build a simple interface to control our new memory (see Fig. 2). Since all micros do not have a VMA line or its equivalent, the design of the interface includes a method of removing the VMA function.



Completed memory interface (left) and 2K memory board (right) using 16 type 2102-1 RAM chips. Note ribbon cable (rear) used in system interconnection. The interface is constructed on perfboard, using wire-wrapped connections. The memory is built on a scrap piece of PC board with etched power leads.

Interface Design — Controlling the Data Flow

The interface has three primary functions. The first and most important function is to determine that the address on the address bus is really intended for our memory. You may wonder how an address could possibly be invalid — until you realize that when adding a 2K memory to a system capable of addressing 65K, some means must be employed to "channel" addresses to the area where memory really exists. This process is called address decode and is a concept common to any memory design. There are address decoding techniques that could make our 2K add-on respond to any 2K range of addresses within the allowable 65K, but for simplicity we will place our memory in the range of 0-2047. The actual process of address decode is simple in practice, requiring only a couple of packages in my design.

Recalling that the data bus in the 6800 is bidirectional, we need some method of making the memory correctly receive and transmit data over a common bus when commanded by the R/W line. This, the second feature of the interface, is accomplished by using *three-state* logic. This logic has the familiar 1 and 0 TTL output levels, as well as an "open circuit" state. Thus, upon command, a gate with three-state output capability may appear to be an open circuit to any other device on the same line. This allows us to parallel (OR-TIE) many gates to the same bus, with only one actually driving the bus at a given time. The design presented here uses three-state logic to drive the data bus. On a memory read cycle, the gates driving the bus are turned on (or enabled) by the R/W line, allowing memory data to flow from the 2102s to the microprocessor. On a write cycle, the gates previously enabled are driven into the open circuit mode, allowing data to flow into the memory (see Fig. 3). The final function of the interface is to buffer the address, data, and control lines. Most MOS microprocessors such as the 6800 can drive only one TTL load per line; thus it is most important not to overload the micro. The interface uses 7400 gates between all micro lines and interface logic. Using the NAND gate as a buffer causes the signal to be inverted, a useful characteristic in some parts of the interface.

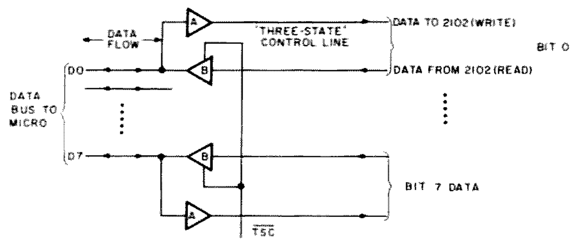


Fig. 3. Three-state logic allows devices to be paralleled on the bidirectional data bus. During a memory write cycle, the TSC line is HI, allowing data to pass from the data bus through device A into memory. The B devices are forced into an open circuit condition, thus not affecting data flow. On a read cycle, a LO on the TSC line turns on device B, allowing data passage from memory to the data bus. Device A, although always enabled, is not affected by read data passing through it, as the 2102 memory's write line is off during a read cycle.

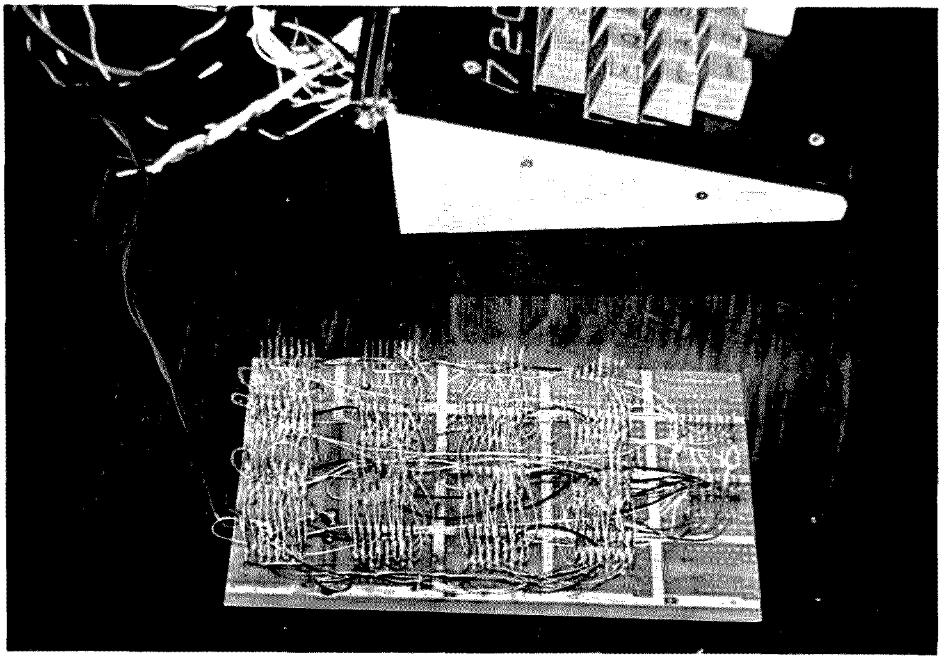
*All numbers are base 10 unless otherwise indicated.



Underside of the 2K memory showing wire-wrap construction. The four distinct "waves" of wire-wrap indicate the number of parallel connections between memory chips. Refer to Fig. 5 for memory schematic.

Some Pitfalls – Be Ye Wary!

One desirable feature of the M6800 microprocessor system can be a possible problem when adding memory. Input and output operations, as well as some system features, use actual memory addresses to initiate and control special functions. For example, micro systems using the MIKBUG® monitor program (such as the SWTP 6800) use locations from $A000_{16}$ – $A07F_{16}$ for system storage, and some locations around 8000_{16} are used for I/O control. These locations must not be overlapped by add-on memory. My system also restricts the use of the upper few memory locations, as they are reserved for system use in a special Read-Only Memory. The point of all this is to be careful where add-on memory is located using address decode techniques. Overlapping system locations can and will cause difficult debugging sessions once the system is running.

Good digital construction practices must be used when working with memory systems. No "software" problem is harder to find than one caused by a hardware glitch. Noise is a problem in systems with add-on memories, as the new memory is seldom on the same board as the original. Liberal doses of power supply bypassing are a must – I used 0.2 uF capacitors in parallel with 0.01 uF ones to bypass power leads. The interface and memory boards are wire-wrapped, but all IC power connections are soldered to the wire-wrap stakes, using #18 bus wire. Interconnection lead length is not critical; mine are 9" between microprocessor and interface and about the same between memory and interface.

The Interface – Linking Micro and Memory

The interface is represented in Fig. 4. All connections between the micro, memory, and interface are made using standard 14 and 16 pin wire-wrap sockets. The cables are ribbon cable with IC header connectors used as plugs. The interface functions as follows: Address decode is accomplished in part by keying on the A10 address line to determine if the address is in the range of $0\text{-}1023_{10}$ (Bank 0) or 1024-2047 (Bank 1). Line A10 allows us to select the bank to be accessed, as described below. The 2102 type RAM is formatted 1024 bits by one bit wide; thus it takes eight RAMs, each contributing a single bit, to make up one memory bank consisting of 1024 bytes (8 bits to a byte). It takes 10 address lines to resolve an address in the range of 1024 bytes; therefore, lines A0-A9 are connected to each 2102. A given bank of eight RAMs is enabled or selected by bringing the enable pin (pin 13) low. The eight enable lines of each bank are in parallel to select eight RAMs at once. Since our memory is to respond only to addresses in the range of $0\text{-}2047_{10}$, all other addresses must be "locked out" by our address decode logic, which works as follows: Any address outside the allowable range will have one address line between A11 and A15 activated. IC1 and IC2A invert and buffer the incoming address lines and pass the resulting five signals to IC3, a 7430 eight-input NAND gate. This gate produces a TTL HI output if any of the eight input lines goes LO, a condition caused by one of the inverted address lines containing an invalid (HI) address. If all five of the address lines in question are LO, the output of the 7430 is LO; this signal, called $\overline{\text{ENAB}}$ (ENABLE), will allow the

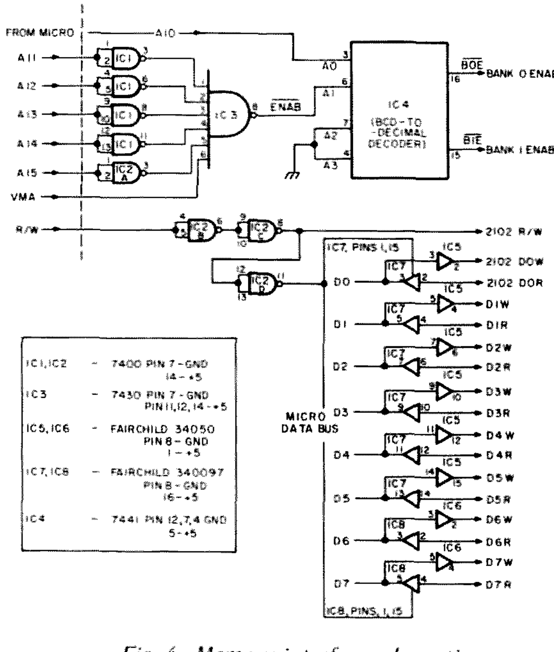


Fig. 4. Memory interface schematic.

memory bank selected to respond to the memory access. Note that the VMA line is also connected to IC3. Recall that VMA is HI if the micro really wants a memory access. A LO on VMA disables the memory exactly as an invalid memory address would.

If your micro does not have a VMA line, tie IC3, pin 6, to Vcc along with pins 11 and 12 (the unused inputs). The above process satisfies the address decode function described earlier. Now, recall that our 2K memory is actually two banks of 1K, each bank having an enable line formed by interconnecting the 2102 enable lines. We must now select the bank desired, as well as using the ENAB signal formed by the decode process. The key to bank selection is based on the fact that line A10 is LO when addresses 0-1023 are referenced, and HI when addresses 1024-2047 are referenced. This fact allows the easy selection of Bank 0 or Bank 1, if the ENAB signal is active. IC4 is a "data decoder" chip, which provides a unique LO output based upon four input signals. For example, if input lines 10-13 contain data "LO LO LO LO," the first of ten output lines will be LO. If the input data is "HI LO LO LO," the second output line will be LO; the first returns to a HI state. The remaining input-output correspondence is not used in this design. Since we only desire to monitor one input line (A10), we connect it to IC4 pin 3. Then, when A10 goes LO, IC4 pin 16 goes LO, thus enabling Bank 0. If A10 goes HI, IC4 pin 15 goes LO, selecting Bank 1. Our ENAB signal is fed to the second IC4 input, pin 6. If ENAB goes HI (invalid address), both of the outputs that enable our banks go HI, effectively disabling the entire memory system. It may be seen that the unused inputs and outputs of the data selector IC4 could be used in more elaborate memory systems. (Refer to the *Fairchild TTL Data Book* for a detailed explanation of the 7441 data selector.)

So far we have determined that the address presented to the interface is valid and the correct bank has been selected. All that remains is to control the 2102 read/write function as well as the three-state data bus drivers. The R/W signal is buffered and inverted by IC2B. This output is re-inverted by IC2C and fed to the 2102 read/write lines to direct data flow within the memory chips. This signal is inverted and used to drive the three-state control lines of IC7 and IC8, the data bus drivers. The additional inversion is required as an active LO signal enables the bus drivers, while a HI signal causes the 2102 chips to output data (read cycle). Finally, note that each 2102 receives address lines A0-A9, as described earlier. The interface board was wire-wrapped on a standard perfboard (see photo). The memory and interface could have been constructed on a single board, eliminating some interconnections, but I chose to make the interface separate as I had a 2K memory board left over from a former project. The choice is left to the reader.

The Memory — Lots of Bytes For a Few Bucks

The 2102 RAM device is an economical choice for memory systems under 8K. Eight of the chips are required for each 1K byte of memory. When constructing a memory board, for each 1K bank, tie address lines A0-A9, the CE lines, the R/W lines, and the DATA IN, DATA OUT lines to form five memory buses. As banks are formed, all buses are tied *except* the CE bus, which is used to select banks. Refer to Fig. 5 for details. The memory may be constructed on perfboard and wire-wrapped, but be sure to provide heavy power lines, as described earlier. Commercial memory boards may be used with the home brew interface if the builder so desires.[2] If this approach is taken, be sure that no address decoding is done on the commercial board, or an address conflict will occur.

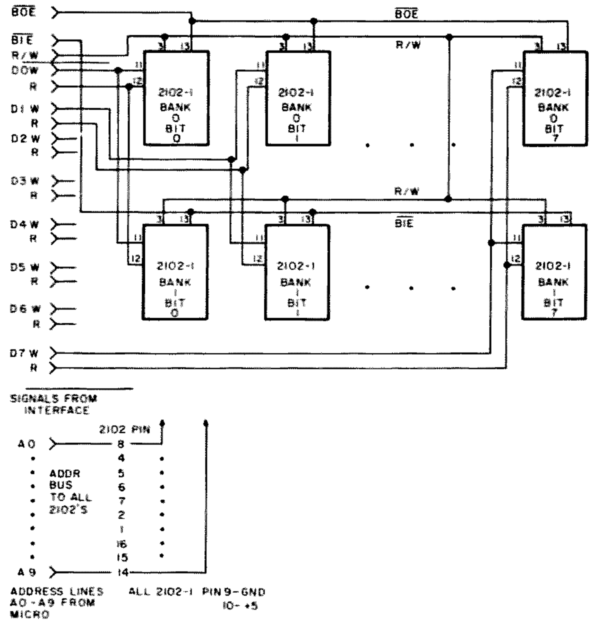

Fig. 5. 2K memory consisting of two banks of 1K each. Note that the A0-A9 address bus goes to all 16 2102-1 RAMs, as does the R/W line. The eight enable pins of Bank 0 tied to B0E from the interface (pin 13). All enable lines from Bank 1 go to B1E. Finally, the D0W and D0R lines go to pins 11 and 12 respectively on Bank 0, bit 0, and Bank 1, bit 0. This pattern of interconnections follows for the remaining D-W, R pairs.

And Finally — Testing

Once the interface has been developed and a memory constructed, the system may be connected to the microprocessor board. Connect all buses as indicated in Fig. 6. Five volt power (Vcc) for the interface can probably be borrowed from the micro, as the drain is under 60 mA. However, 2K of 2102 RAM requires upwards of 700 mA, dictating a separate supply unless the main supply has the beef. Remember to tie all ground leads if using more than one 5 V source. In some cases it is necessary to remove existing memory chips from the micro board if they conflict with the add-on memory. For example, my Motorola MEK prototype board had several 128 byte RAMs in low memory that would have conflicted, so I popped them out and used them in another system.

After making all interconnections and checking for obvious shorts, etc., apply power and check for smoke — aargh! If all looks good, insert the ICs, reapply power, and then attempt to read a new location. Many 6800 systems use the Motorola MIKBUG® monitor, which enables the user to execute an "M" command to examine memory. A random pattern should be present. Now attempt to rewrite the location, checking for correct data. Systems with front panel switches, such as the MITS 680, can be checked by manually reading/writing new locations. Next, check the location following the last one supported by the add-on (2048 in this system). It should be zero, indicating

The "Big Three" Motorola MEK 6800 microprocessor evaluation board (left) provides computing power for RTTY system. The memory interface and memory board providing add-on memory capability are alongside. The converted television set in the background provides temporary display capability, while using a Model 19 (not shown) for hard copy. The Sanders 720 ASCII terminal may also be used "on-line" with software ASCII/Baudot conversion.

correct address decode. Also, try locations that are 2K multiples of the add-on, such as 4096, etc. They, too, should be zero. If all is OK so far, load and execute a program — better yet, write that new application! Don't get lost in all that new memory.

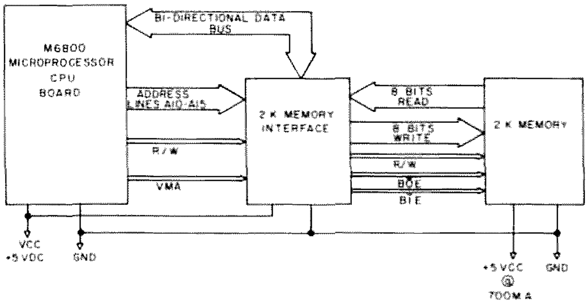

Fig. 6. System interconnections.

In Case of Problems — Don't Break the Board

The most likely problem area is in the address decode logic. If locations read/write erratically, check for address overlap with existing memory or I/O devices. If two devices answer an access request, an error is sure to result. Look for *patterns* in errors — if a single bit of multiple bytes is set or off continuously, check for memory board data line wiring errors. Repetitive errors are easy to isolate due to the fact that so many elements are tied together. Don't discount the possibility of a bad 2102. They are MOS devices, capable of being zapped by static charges during installation. Handle them with care. DO NOT attempt to use old 2102 devices without the "-1" suffix. These are 1000 ns devices and much too slow to be used with 6800 and 8080 systems, especially considering the propagation delays introduced by the interface. Use 2102-1 (500 ns) devices, available from several *73* advertisers.[1]

And Finally . . .

After adding a couple of K to your system, applications should suggest themselves at every turn. In order to run BASIC or other language processors, at least 8K will be required. Hopefully, having built the simple 2K system, you will be encouraged to tackle a larger memory system using some of the suggested techniques. A future article will discuss the use of dynamic RAM devices in large memory systems, should you exhaust your 2102 space. Until then, however, *good luck* and *good programming.* ■

A Software Replacement for the Muffin Fan

-- IC cooling program

One of the most fundamental and oft-forgotten principles of electronic tinkering is that of semiconductor heat generation. Whether that tinkering involves a new design, or modification of an existing design, heat calculations are usually a must. I've presented here a simple and straightforward method of heat calculations, designed to take the "black magic" aura away. Also included, for the individual with access to a computer, is a lazy man's program (called Pele) which performs all the calculations with ease.

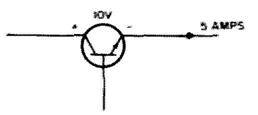

Fig. 1. 2NXXX pass transistor dissipating 5 Watts of power.

For this discussion, I will consider only transistors in the examples given. Obviously, the same method can be applied to diodes and ICs and, in fact, the last example using the Pele program was based on a voltage regulator IC. It should also be pointed out that this is only one method of calculating heat generation and there are other equally good procedures.

The first question I usually have regarding a semiconductor is, "How much power can I pour into the little devil without blowing its brains out?" If I were not wise in the ways of the world, I might take the following approach (for a dc application): look up the maximum current and voltage ratings, and let it go at that. For example: I am planning to use a 2NXXX as a pass transistor in a power supply. The maximum ratings (taken from an actual data sheet) are 70 volts maximum collector to emitter voltage and .7 Amps maximum collector current (I_C). Since I am conservative by nature, I plan to drop only 10 volts across the pass element and pull .5 Amps through it. Therefore, I am dissipating 5 Watts in the device, in the form of heat. This might seem reasonable, since the device is advertised as a 5 Watt transistor. Do I really know what I am doing? Let's see. Fig. 1 indicates the situation we are about to analyze.

Analysis Procedure

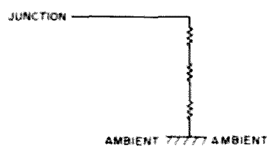
Step 1. Draw a thermal resistance sketch of the device and its surroundings. Assume a heat sink will be used. Each thermal resistance (Θ) can be indicated by the symbol for a resistor. See Fig. 2.

Step 2. Next add to the diagram the following (from data sheet):

Θ_{JA} – the junction to air thermal resistance (°C/W).

Θ_{JC} – the junction to case

Fig. 2. Step 1: Thermal resistance sketch.



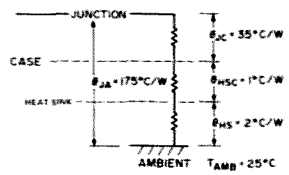


Fig. 3. Step 2: Thermal resistance sketch.

thermal resistance (°C/W).

Θ_{HSC} – the heat sink compound (or silicon washer) thermal resistance (°C/W); if unknown, specify 1°.

Θ_{HS} – the heat sink thermal resistance (°C/W); mnemonic of Θ_{SA} also used instead of Θ_{HS}.

T_{AMB} – the ambient temperature (°C).

Note that with the exception of the last parameter all units are the same, i.e., degrees C per Watt (°C/W). This is the standard unit of thermal resistance. See Fig. 3.

Step 3. Multiply the total power dissipated (in Watts) in the device by Θ_{JA}. This will tell us how hot the junction will become (*above* ambient) without a heat sink. For our example, $P_D \times \Theta_{JA}$ = 5 W x 175°C/Watt = 875°C above ambient = 900°C. That is pretty warm, and it looks like I *didn't* know what I was doing; the maximum junction temperature as listed on the data sheet is 200°C. What happened to the 5 W advertisement? If I had read the fine print, I would have noticed that this 5 W rating applied only at case temperature (T_C) up to 25°C. If I

Fig. 6. The Pele program.

cooled the case with an infinite heat sink, like liquid nitrogen, I might get away with it.

Step 4. To find the case temperature without a heat sink, subtract the quantity ($P_D \times \Theta_{JC}$) from the previously calculated junction temperature. For our example:

Case Temp. = 900°C − ($P_D \times \Theta_{JC}$)
= 900°C − (5 W × 35°C/W)
= 900°C − 175°C
= 725°C

So now we have found that without using a heat sink, 5 Watts of power will heat up the junction of the transistor to 900°C and the case to 725°C. In other words, that 2NXXX will be vaporized!

Calculations with a Heat Sink

Step 5. How much will a heat sink help? To find out, add up the individual thermal resistances on the right side of Fig. 3 ($\Theta_{JC} + \Theta_{HSC} + \Theta_{HS}$) and then multiply by P_D. In our case: 5 W × 38°C/W = 190°C above ambient = 215°C junction temperature. This is a lot closer, but still above the specification for maximum junction temperature.

Step 6. Find the case temperature in much the same way as before. Subtract the quantity ($P_D \times \Theta_{JC}$) from the junction temperature:

Case Temp. =
215°C − 175°C = 40°C

Step 7. Calculate the temperature of the heat sink by subtracting the quantity ($P_D \times \Theta_{HSC}$) from the case temperature.

Heat Sink Temp. =
40 − (5 W × 1°C/W) = 35°C

This is an interesting fact, because it shows that while the heat sink is relatively cool (35°C), the junction is very hot. (Remember that the next time you think your calibrated fingertip is telling you something about how hot a device is getting.)

Step 8. Relax. In my case I shall ponder the acquisition of a new device. Let's summarize:

2NXXX Transistor
(dissipating 5 W)

	25°C Ambient
Without Heat Sink	
Junction Temp.	900°C
Case Temp.	725°C
With Heat Sink	
Junction Temp.	215°C
Case Temp.	40°C
Heat Sink Temp.	35°C

For this example, a 25°C ambient was assumed. Naturally the highest operating ambient should be chosen for this value.

Sometimes a specification is given for power dissipation at 25°C with no heat sink. In this case (T_a), the free air dissipation was 1 Watt (this would have told me right away I could not use the device at all without a heat sink, because I was dissipating 5 W).

A flowchart of the foregoing method is given in Fig. 4. This flowchart was also used to generate a program in BASIC on a 370 computer.

The Program

The Pele program can input data in any one of three ways: (1) after each text question; (2) after all the text questions; or (3) directly, without text questions. Pele then calculates the junction and case temperatures without a heat sink and also the junction, case and heat sink temperatures when a heat sink is used. It does both of these at three different ambient temperatures with 25°C ambient as the center line value. If the power dissipated at 25°C (P_D) exceeds T_a, Pele will only print out the "with heat sink" temperatures. If the junction temperatures exceed the maximum inputted value, Pele will print out a caustic remark. An actual problem which was run using Pele is shown in Fig. 5. The Pele program is listed in Fig. 6.

Finally, why name a program after a soccer player? Didn't you know? Pele is the Hawaiian God of Fire. ■

1,000 WPM Morse Code Typer

-- for the bionic brass pounder

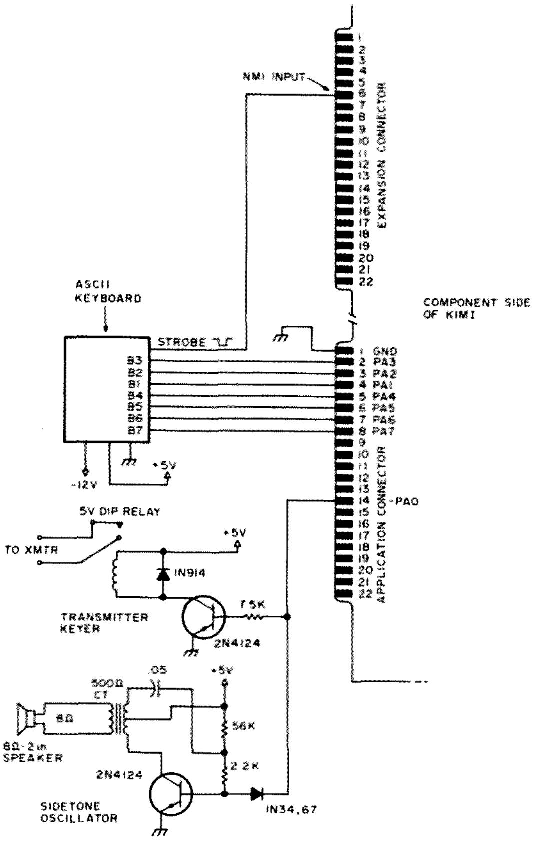

Fig. 1. Schematic for Morse code keyboard hardware. The A I/O port on the KIM is used as a parallel data link for the ASCII keyboard and as a serial output for the Morse code. This serial output can be used to switch a sidetone oscillator and/or a CW transmitter.

James W. Pollock WB2DFA
6 Terrace Avenue
New Egypt NJ 08533

Up until the recent microprocessor boom, a project such as a Morse keyboard presented a formidable design, construction, and debugging project even for the well-versed hobbyist. The program presented here is a much easier software approach to this hardware problem using the KIM-I microcomputer by MOS Technology. The principles used to design this program are suited for other systems equipped with a programmable, read-write interval timer.

The KIM-I is equipped with such a timing device embedded within the architecture of its MCS6530 peripheral interface chip. This addressable timer is used extensively to define the timing of dots, dashes, spaces, spaces between letters, and spaces between words under program control. Reading and writing into the timer is just like an R/W operation in RAM memory.

The features of the software package are as follows:

1. Variable code speed from 9 to over 1,000 words per minute (for those of you who are bionic brass pounders).
2. 256 character First In, First Out (FIFO) buffer memory for typing ahead capability. The third page of RAM (0300-03FF) is used for this buffer storage.
3. Configuration software (I/O assignments and initializing) is provided for instant "GO" upon loading, or power turn on, if the user decides to use PROM for the program storage.
4. The program resides in a field of 256 bytes, which lends itself well to unexpanded systems (i.e., using just the memory available on the KIM-I board).
5. Excellent learning tool for self-instruction in Morse code.

The folowing guidelines were used for Morse code character synthesis: DOT = 1(t); DASH = 3(t); SPACE = 1(t); Space between letters = 3(t); Space between words = 7(t).

The interval timer on the KIM defines the basic time period, (t), under program control for character timing. The duration of this interval has been measured to be about 1.08 milliseconds, multiplied by XX_{hex}:

$(t) = 1.08$ milliseconds x (XX_{hex})

XX is any hex value from 01 to 7F.

The timing interval (t) ranges from 1.08 ms to 138.4 ms. The program fetches the code speed byte from 17BE in the KIM RAM. Before program execution is begun, the pro-

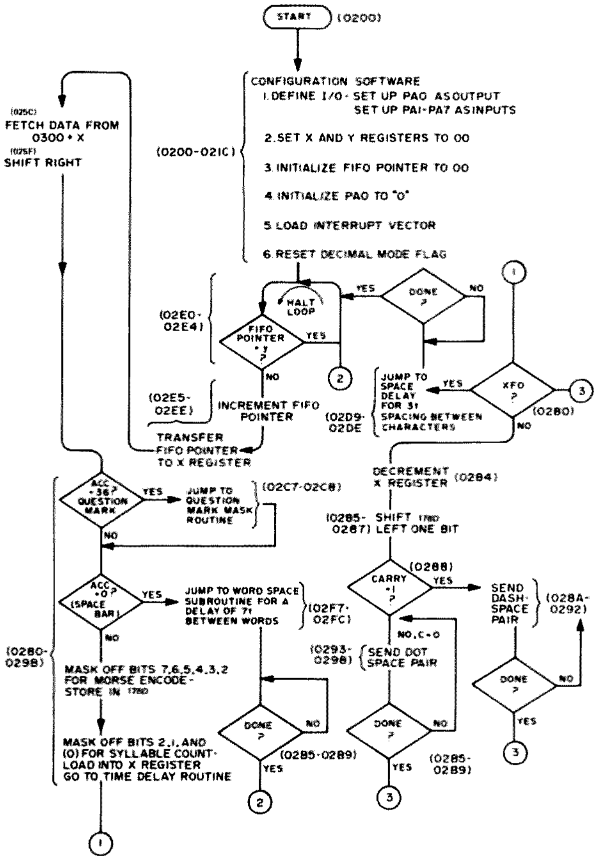

Fig. 2. Program flow chart for Morse code keyboard with FIFO buffer.

grammer must load the code speed byte into 17BE by hand using the hex keyboard on the KIM.

A value of $1A_{hex}$ in location 17BE yields a code speed of approximately 43 words per minute. A 20 wpm rate can be programmed by entering 37_{hex} in 17BE. 7F will correspond to 9 wpm.

The Morse characters are synthesized in dot-space or dash-space pairs. The completed character is followed by a delay of 2(t) to provide a total spacing of 3(t) so that individual letters are easily discernible. This spacing is added automatically by the program, and does not use valuable FIFO memory space. One depression of the SPACE bar on the ASCII keyboard provides a word spacing of 7(t).

Character Loading

The software has an interrupt routine that loads each key depression into successive memory locations in the FIFO buffer. This loading process occurs at any time during program execution, so that the operator is synchronously independent of the system. The interrupt routine for loading keyboard data occupies addresses 02CC-02D7. Each keyboard stroke is stored in successive memory locations beginning with 0300. The keyboard STROBE pulse is used to trigger the non-maskable interrupt (NMI) input of the KIM to signal the microprocessor that data is available for storage and processing. Thus, the Morse code keyboard is an interrupt driven device. (NOTE: Please observe the polarity of the STROBE pulse out of your ASCII keyboard. The NMI input of the KIM is normally high; if the STROBE pulse out of your keyboard is normally low, then you will have to invert it. I did this with my keyboard by using the $\overline{Q}$ output of the STROBE one shot.)

Character Fetch

Upon completion of stepping through the configuration software, the program jumps to location 02E0. If no data has been entered into the FIFO, the program enters a HALT loop by branching between 02E0 and 02E3. When data is loaded into the FIFO via the ASCII keyboard, the Y register is incremented to a value greater than the FIFO pointer in address 17BF. When these two registers are not equal, the character fetch from the FIFO begins and continues until the FIFO pointer has incremented up to the value contained in the Y register. The Y register points how far into the FIFO the last character was entered, while the FIFO pointer designates the next character to be fetched and processed. When the FIFO pointer in 17BF increments up to the value in the Y register, the machine has finally caught up to the operator, and the program reenters the HALT loop.

From ASCII to Morse

The conversion of ASCII into Morse code begins at 025C when a byte is fetched from the FIFO. Since PA∅ (bit zero of the A I/O port) is used as an output, the ASCII entry ports have been shifted up one bit from PA∅. This has the net effect of shifting the incoming data one bit to the left, even before the computer has asked to receive it. To compensate for this, the LSR instruction at 025F restores the identity of the parallel ASCII data by shifting it right one place.

As an example, assume that the ASCII code for C is in the accumulator after the LSR instruction execution. The ASCII code for C is 100 0011 or 43_{hex}. This value is transferred to the X register, then the accumulator is loaded with data at the calculated address of 0200 + 43 or 0243 as indexed by the X register. 0243 is in the LETTERS "lookup" table portion of the program. You will note that the contents of this address is $A4_{hex}$ or $1010\ 0100_2$. The encoding information is contained within this binary string.

Within this encoding byte are:

1. The type of syllable to be synthesized: dash-space or dot-space.
2. The number of syllables that will be synthesized to make that Morse code character. A syllable defined herein is either a dot-space or a dash-space pair.

The separation of these "subcodes" is performed by using the AND instruction in conjunction with a masking byte that will extract the information we need to execute the process.

To get the information in the first six significant bits from 1010 0100, this byte is ANDed with FC_{hex} or 1111 1100.

Case I:

1010 0100 (A4)
1111 1100 (FC)
1010 0100 RESULT

The first four significant bits are: 1, 0, 1 and 0. The 1s represent dashes and the 0s represent dots. The order in which dots and dashes will be sent from the computer is dictated by the arithmetic shift left (ASL) instruction. The ASL instruction shifts bit 7 to the left, into the carry bit, and zeros into bit 0. Thus the result of the first shift is:

(C)	B_7	B_6	B_5	B_4	B_3	B_2	B_1	B_0
1	0	1	0	0	1	0	0	0

Since the carry flag (C) is a 1, a dash-space pair will be sent. One more ASL will yield:

(C)	B_7	B_6	B_5	B_4	B_3	B_2	B_1	B_0
0	1	0	0	1	0	0	0	0

Since the carry flag (C) this time around is a 0, a dot-space pair will be cranked out.

The process continues until all of the syllables have been synthesized. The number of times that an ASL instruction will occur in the course of sending a complete Morse code character is determined by the three least significant bits, B_2, B_1 and B_0. Isolating these bits is done by ANDing the encode byte A4 with 07 as follows:

Case II:

```
1010 0100 (A4)
0000 0111 (07)
0000 0100 RESULT
```

The result of Case II is transferred to the X register. The X register is decremented for each (ASL) shift. When X has been decremented to 00_{hex}, a complete character has been processed. In this case, four (4) syllables are sent to synthesize the letter "C" (– · – ·).

All letters, numbers, punctuation and abbreviations are processed in this manner. When X has been decremented to 00_{hex}, the program branches to a subroutine that adds two extra timing intervals, 2(t), to the last syllable so that letter spacing is 3(t). This subroutine is located at 02F0-02F6.

Syllable timing and spacing are done by subroutine groups that funnel the program through one central time delay loop, 02AE-02C6, for maximum coding efficiency.

Special Keys

Provisions have been made for "lookup" table values for generating abbreviations and the punctuation marks used most frequently by hams.

1. The colon (:) key is coded to produce AR.
2. The semicolon (;) key is coded to produce DN.
3. The equals (=) key is coded to produce SK.

```

4. The DEL key is coded to produce BT.
5. The period (.), comma (,), and the question mark (?) keys have been coded to produce their respective Morse code equivalents.

Operating Hints

In the interest of minimizing program listing requirements, the LETTERS lookup table, 0240-025A, was designed around the uppercase alphabet characters. The lower case alphas have been omitted for two reasons:

1. There is no distinction between upper and lower case letters in Morse code.
2. About 99.9% of existing software is written in upper case, and most teletypes, terminals, and ASCII keyboards that don't have the upper/lower case feature are coded for the upper case letters. Shift and lower case characters are not permitted.

The first step in the start-up is loading the program. Since the listing is quite lengthy, loading the program by using the hex keyboard each time the power is turned on is somewhat of a pain in the ASCII. I suggest that after you have checked your data entries, you take advantage of the audio tape dump program and hardware that is already on the KIM, so that you will have it permanently stored. Loading the computer from the cassette takes about 40 seconds for this particular program.

During the loading operation, the sidetone oscillator and transmitter switch will be enabled. A toggle switch, in series with the speaker to temporarily disconnect it until the system is configured by the software, is recommended.

Before you pass GO, be sure that you load the code speed byte in location 17BE. Use values less than or equal to 7F. In order to change the code speed after you have the program running, you will have to stop the program and load 17BE from the hex keyboard.

Since the KIM is a relatively new machine with little software support, you may have to move the program buffers, 17BC-17BF, to some other locations in the RAM memory space as new hardware and software are introduced and marketed. I chose to use those locations because they reside in the 64 byte RAM in the 6530 interface chip. This still leaves pages 00 and 01 free for expanding the program within the confines of my unexpanded system. ■

It Works! The First Time!

-- the Seals Electronics memory board

It all started while I was looking through the June issue of *73* and came upon an ad for an 8K memory board. This particular ad made me realize that if the claims of the manufacturer were true, this board would be a very nice addition to my computer system.

Upon investigation of the manufacturer of this particular board (Seals Electronics) at the local computer club, I heard a very strange rumor. That is, that it was possible to obtain this 8K static memory board in only 10 days from the date that the order was received. I was quite sure that it was actually 100 days, but the temptation was more than I could resist. On June 16th I placed my order.

As soon as I dropped the order in the box I was gripped with fear, realizing that the interest on my money would probably be collected by the company for some time, at my expense. I resigned myself to receiving the memory board in 1977.

On June 23rd the postman came carrying a box three inches deep and a foot square. Sure enough, it was from Seals Electronics. I didn't open the box for a long while; I just stared at the box in disbelief and was somehow comforted by its shape. This must be a good sign, I thought.

Finally, I opened the box and peered inside. What a pleasant surprise. I viewed a large plastic envelope that contained four smaller parts packages. All of the components were of top quality. But what about the board? I quickly tore open the package that contained the board and examined it. It was beautiful! Not only was it first class in appearance, but it had no jumper wire holes. It had a solder mask on both sides and was silk screened on the component side. And, there was an assembly manual and two other documents.

I began reading the manual and, to my surprise, I could understand it. It was written in modern English, and even *I* could understand it. It described the assembly, installation and standby battery hookup. The theory of operation was described so that it could be easily interfaced with a home brew project. Could it be that this manual was written for the hobbyist?

Two more pleasant surprises were yet to come. Upon examining the two remaining documents, I found a multicolor full size printed circuit board layout and a beautifully done foldout schematic of the board circuitry.

My enjoyment increased as I began construction. I followed the instructions and the memory began to take shape. First I installed the diodes, then the resistors, next the regulators, and then the address selection switches. Oh yes, and the *sockets*! This kit was supplied with sockets for all ICs! I was becoming convinced that a tremendous amount of thought had gone into the planning of this kit.

Another thing that struck me as I continued to build the kit was that all the holes were the correct size. Not once did I have to file down a lead and stand on my pliers to insert a component lead through the board.

The sockets fell into place and I even tried to make a solder bridge on the board, but was unable to accomplish this due to the almost foolproof solder mask. I was now convinced that anyone could build this kit without error if he simply followed the instructions. The last item of construction was the placement of the capacitors and this also went without a hitch.

Now for the ICs. As I began to insert the ICs in the sockets, another thought struck me. It was impossible to damage them with the old soldering iron.

Finished! I quickly looked the board over with my magnifying glass and, finding no problems, placed it before me with a sigh. After gloating for a few minutes, I picked up the card and headed for the computer. Snapping the address switches into the proper position, I then placed the board in the slot and prepared myself for the big moment. The familiar click of the power switch seemed to be more meaningful and the whir of the fan and lighting

of the LEDs joined in to indicate that all was okay.

Now for the test. First I addressed the memory and deposited a few bytes of data. Everything seemed to be working. Next I loaded BASIC into the memory and it worked flawlessly. It worked! And the first time, too.

When my wife called me to empty the garbage I realized that I was not dreaming. I began to consider what performance tests I might use to prove that this memory board was not all that it was cracked up to be. I was really challenged now, and was determined to find a problem with this board. After all, there just had to be some shortcomings somewhere! Besides, my reputation as a skeptic was at stake.

With these purist concepts in mind, I set out to test my newly constructed memory board.

My first plan of attack was to prove that no static memory could come close to my present dynamic memory in low power consumption. To accomplish this, I cut the three power leads between my last extender board and the other boards connected to the computer bus. I stripped one quarter inch of insulation from the free ends of all leads and melted some solder on the exposed wire to aid in soldering them during testing. I then resoldered two of the power leads, restoring normal operation to those two sources of power. I connected my ammeter between the two remaining leads.

The next step was to install two dynamic boards to give a total of 8K of memory. Placing them in the test location, I then applied power and recorded the ammeter reading.

I repeated this process with the two remaining power leads to the boards, and recorded the results.

Now for the new memory board. I installed it in the same manner and measured the five volt power line (the only one required for the new memory).

After comparing the results, I was surprised to find that the new low power static board consumed only twenty percent more power than the two dynamic boards. For all practical purposes, the power consumption is an even swap.

Not being one who gives in easily, I continued my testing. This particular board was advertised as having the memory of an elephant, or something to that effect. So I proceeded to examine this aspect of its operation.

There is a very unique feature built into this board; that is, there is a diode switching network between the normal power line to the memory and the battery standby line to the memory that is brought in on pin 14 of the memory board. (This position is not used on the bus line of the Altair and other similar computers.) This means you can connect a battery across pin 14 and ground, and when power is interrupted, the memory is automatically switched to the standby source to retain memory content.

To test this feature of the memory, I constructed a simple power supply capable of maintaining three volts under load when connected to the memory while the computer was turned off. I then soldered a small piece of wire on the free end of the extender board at location 14. The positive lead from the supply was connected to this wire and the negative lead from the supply was connected to logic ground (pin 50).

Not wanting to start in a small way, I loaded BASIC in the memory and immediately turned off the power. I waited for a few minutes, switched on the power, reloaded the first byte of data (location 0) that was lost by the computer, depressed the run switch and up came BASIC. This was a milestone in the operation of my computer system.

I then decided that a longer period of testing was needed. I followed the same procedure as before, but this time I left the computer off for 24 hours.

When I returned to resume testing I first touched the memory regulator heat sinks to determine whether cooling would be necessary during standby operation. They were cool! When I powered up the machine as before, BASIC came up without a problem.

By this time I was completely sold on my new 8K memory. I was patting myself on the back for what I thought was extremely good judgment on my part in selecting such a nice piece of equipment. (I have not been noted for this quality in the past.)

I pondered for some time after the completion of this testing to be sure that nothing else could be done by me to break down the resistance of the memory.

It then occurred to me that perhaps a good test would be to operate the memory with a disc operating system. Since I happened to have a brother-in-law with such a system, it seemed that a trip to his place was in order.

Upon arrival, we installed the memory board in his computer and, as you have probably guessed, it worked perfectly.

In conclusion, I would like to take my hat off to the folks at "Seals Electronics," and to what I believe is a long awaited answer to the dreams of the computer hobbyist. It is obvious that they have done their homework in producing a kit which can be built with more than a reasonable expectation that it will work when finished.

If you plan to purchase memory in the future (and who doesn't?), be sure to include this one on your list of considerations. I think you'll be very happy with it. ■

The New Improved TT Decoder Updated

- - better

William Hosking W7JSW
8626 E. Clarendon
Scottsdale AZ 85251

One of the things I have enjoyed most since I started writing for *73* has been the interchange of ideas with readers. I am always getting new ideas from calls and letters. My recent article on a TT decoder (April, 1976, p. 52) probably generated more interest and applications than any of the others. This short article is to share a couple with you.

Most users had to build up a supply or regulator in order to get the 5 volts required by the decoder board and, since I had quite a bit of room left on the board, I subsequently got the artwork redone to include an LM309H type regulator on the board. It worked out nicely and the regulator pads can be jumpered if the regulator is not wanted.

It's funny how small things can slip by, particularly where printed circuit boards are concerned. After I had wired several of the boards for people, I suddenly realized that I had not provided a PC pad for the negative power lead . . . back to artwork changes again.

A ham in the area who also uses commercial radio services came up with an excellent application and very useful modification of the basic circuit and board. The man has a business radio in his home and one in his truck, and uses them to contact his wife for messages, etc. The channel he is on is a common user channel with many other subscribers. His wife, as do many others, got tired of hearing all the other chatter on the radio all the time. The man decided to use my decoder to turn his base station speaker audio on and off. He could do the receiver modification himself and then acoustically couple the touchtones in his mobile radio.

The only problem that came up with this arrangement was that the wife couldn't turn the speaker back off locally after it had been functioned on. The application and the problem led me to the circuit modification shown in Fig. 1. The only change that had to be made was to add two diodes such as 1N4148s or 1N914s to the inputs of the "off" NAND gate and a normally open push-button switch. The switch then shorts the diodes to ground, causing the output of the gate to go high and reset the output latch. In this case the user mounted the small push-button directly on the front panel of his commercial base station and the circuit board fits easily inside the radio. He is using the decoder relay contacts to interrupt the speaker audio.

This is just one of many possible applications. Many people have built the circuit to control autopatches using a "*" on and "#" off. If you have used this circuit for some neat application, I would be very happy to hear from you. ■

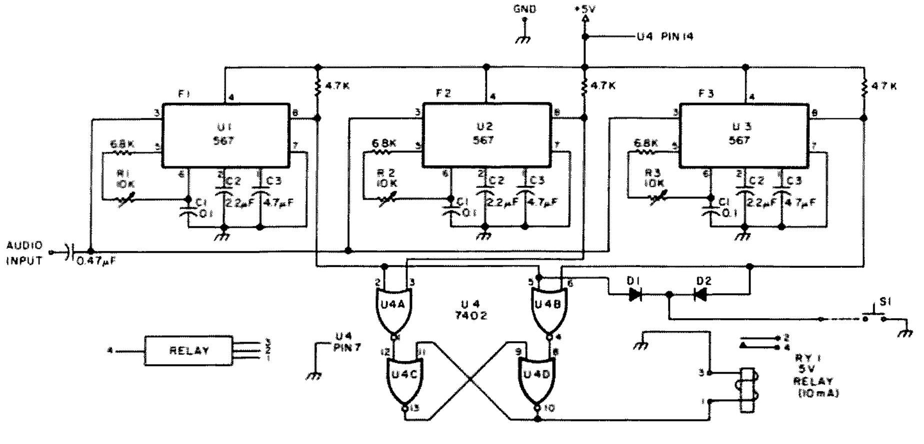

Fig. 1. Tone decoder with added regulator circuit and manual reset circuit. Diodes D1 and D2 (1N4148/1N914) are added to the circuit board and S1 shorts their junction to ground. Printed circuit boards are available from CONTACT Electronic Research and Development, 35 W. Fairmont, Tempe AZ 85281 for $5.50 postpaid. Wired and tested versions are also available.

The Polarity Changers

- - plus to minus

A problem often arises with some IC or transistor circuits when just a modest amount of negative voltage is needed to bias a switching circuit or to power an IC circuit stage that works best when it is powered from equal positive and negative supply potentials. For home station equipment, this situation is easily resolved by constructing a power supply which provides the necessary positive and negative outputs. For battery-operated equipment, an extra battery can always be provided, but this adds to bulk, eventual cost and perhaps even erratic operation at some time since the separate batteries used for positive and negative supply voltages will not age at the same rate. The greatest problem is usually with adapting such circuits to mobile operation where only +12 volts is available. Either a battery for a negative supply has to be used, the circuit modified for single supply operation or, as is usually the case, the idea given up of using a particular circuit for mobile operation.

This article describes a number of ways by which a negative supply voltage can be generated when only a positive source is available. Those who still remember vacuum tubes may also remember that this was also a problem then for mobile operation when tubes required a negative bias voltage. The usual solution was another winding on a vibrator power supply transformer or on a dynamotor. But, some manufacturers even then did try more ingenious approaches, and they are the basis of the circuits that are used these days to generate that needed negative supply potential.

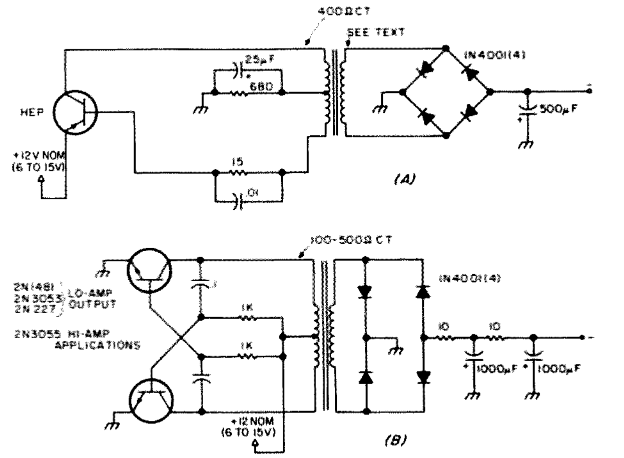

Fig. 1. Two forms of oscillator circuits which can be used to form a negative voltage supply. Output voltages and currents are available over a wide range depending on the transistors and transformers used as explained in the text.

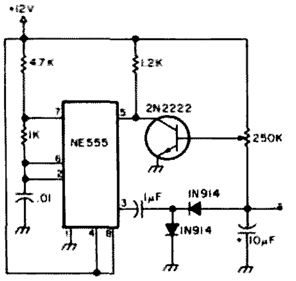
Basically, there are two approaches that can be used to generate a negative ground potential when only a positive to ground potential is available. One is to build an oscillator (anywhere from audio to rf) which has a transformer output isolated from ground. The transformer output is treated like the secondary of an ac transformer (rectified and filtered) to produce a negative voltage. In tube days, rf oscillators were popular because high voltages for bias purposes could be developed across their tuned circuits. The other basic approach is to use a switching circuit to charge a capacitor with a positive supply. But, between charging intervals, additional circuitry literally lifts the capacitor up and turns it around with respect to ground, and it supplies a negative potential. So, the capacitor is alternately charged and electronically flipped around and discharged.

The following oscillator circuits are not the simplest form of positive to negative supply generators possible. Still simpler circuits are possible but they require special transformers, whereas the two circuits shown need only simple, readily available parts.

The circuit of Fig. 1(a) is basically just an audio oscillator with a transformer coupled output. It can be constructed using a wide variety of PNP general purpose transistors and with transformers having varying turns ratios so that output voltages of from 6 volts to 20 volts can be obtained. The secondary voltage is then rectified using a standard bridge rectifier circuit and a 500 mF filter capacitor. Not too much filtering is required since the oscillator produces a fairly good sine wave output. One may have to connect miniature transistor output transformers back-to-back to

Fig. 2. The inexpensive 555 timer IC is the heart of this negative supply which provides a variable output up to -10 volts. Note that the 1 mF capacitor by pin 3 is not an electrolytic type.



obtain a desired output voltage, depending on which types are available locally. For instance, one might use a 400 CT to 8 Ohm transformer back-to-back with an 8 Ohm to 10k transformer to get a voltage step-up. Some experimenting and breadboarding is necessary, but just about any desired voltage can be generated by using different transformer ratios and types of rectifier circuits (half wave, full wave or bridge). Generally, using low power transistors and the usual 99 cent 300 mW transistor transformers, output loads of up to 10 mA can be accommodated.

Fig. 1(b) is a standard multivibrator circuit with component values chosen so it operates at about 7 kHz. The idea is basically the same as in Fig. 1(a), but this circuit produces a square wave output and, depending upon the power transistor used, output currents of an Ampere or more can be generated at various voltage levels. Some 24 CT filament transformers will work well in this circuit. Otherwise, standard transistor output transformers have to be used either singly or back-to-back to get the desired step-up in voltage. Transistor output transformers or interstage transformers rated as 1 Watt, such as Stancor TA-4 or Allied 6T8HF, will do nicely with any of the low/medium power transistors mentioned in Fig. 1(b) to produce outputs in the 12 to 15 volt range at up to 100 mA load. The square wave output of the circuit requires that a bit more elaborate filtering be done, as shown in Fig. 1(b), to get a smooth dc output. Also, square wave generators will have rich harmonic outputs. The 7 kHz operating frequency for the multivibrator is a compromise between an operating frequency that is above the audio range of most audio communications circuits with which it is likely to be used and yet within the efficient frequency operating range of most inexpensive transformers. Nonetheless, if the supply is to be used with rf circuitry, careful power supply bypassing to the multivibrator and even shielding in extreme cases may be necessary to prevent hash in the rf circuits.

The circuits of Fig. 1 should satisfy most needs and can be built reasonably inexpensively. However, in these days of ICs, it would not be fair to omit some more sophisticated approaches to the negative supply voltage problem. Both of the following circuits appeared originally in *Electronics* and provide negative voltage generation along with regulation of the output voltage.

Fig. 2 uses the ubiquitous 555 IC timer. The 555 is operated as a free-running pulse generator. The pulse output frequency and pulse width are basically set by the RC components between pins 7, 6, 2 and 1. However, a control voltage applied to pin 5 can vary the pulse repetition rate. Output is taken from pin 3 where first a capacitor isolates the output from a ground reference and then the output is rectified and filtered. The output voltage level can be set anywhere from 0 to -10 volts by the potentiometer in the base of the 2N2222. This potentiometer, for any given setting, compares the output voltage to the supply voltage. If the output voltage decreases, the 2N2222 is turned further on, causing the control voltage on pin 5 to come closer to ground and hence to increase the pulse output rate. This, in turn, charges up the output 10 mF capacitor more often and brings up its voltage. The quality of the regulation depends on the output current demanded. It is about 5% at 10 mA output. Greater outputs can be supplied but then the regulation will become poor.

Fig. 3 shows another supply/regulator circuit that can supply fixed output voltages over the range of about -5 volts/30 mA to -15 volts/13 mA from a +15 volt supply. Thus, it can supply a bit more current than the circuit of Fig. 2 and can supply -12 or -15 volts when a +12 or +15 volt source is available, which is an advantage in many applications using operational amplifiers. The circuit uses an IC hex-inverter and a single transistor. Two of the inverters form a square wave oscillator. The other four inverters are paralleled as drivers. When the output goes positive referenced to ground, the 1 mF capacitor charges through the 1N914 going to the collector of the 2N3904. When the output goes towards ground, charge is transferred from the first 1 mF capacitor to the output 1 mF capacitor as the second 1N914 conducts. The output 1 mF capacitor now has a voltage across it which is negative referenced to ground. This transfer of charge between capacitors continues until the voltage buildup across the output 1 mF capacitor breaks down the zener diode. Then, the 2N3904 is turned off and the transfer of charge stops until the load current drain again causes the output voltage to fall below the zener voltage. Thus, the circuit is self-regulatory.

The circuit as shown will produce only 5 volts negative output from a positive 15 volt supply. This can be increased by using the alternative voltage multiplying circuit shown in Fig. 3 to produce -15 volts. -12 volts can be produced from a positive 12 volt supply with the same circuit by using an approximately 13 volt zener. The 74C901 hex-inverter operates from up to a positive 15 volt supply and can produce a full -15 volts when used with the voltage multiplying circuit. However, if only a positive 5 volt source is available and -5 volts is needed, the basic circuit of Fig. 3 with the voltage multiplying circuit can be used with a simple SN7404 hex-inverter. An approximate 5.6 volt zener will suffice for the zener reference diode in the base circuit of the 2N3904.■

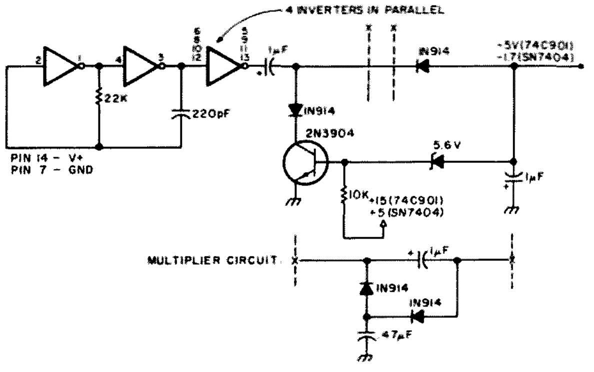


Fig. 3. Negative voltage generation circuit using a hex-inverter IC. If the multiplier circuit is inserted between points X-X, the basic output voltage will be the same as the positive supply voltage. The zener in the base of the 2N3904 must always be rated at 0.6 to 1 volt more than the final negative output voltage.

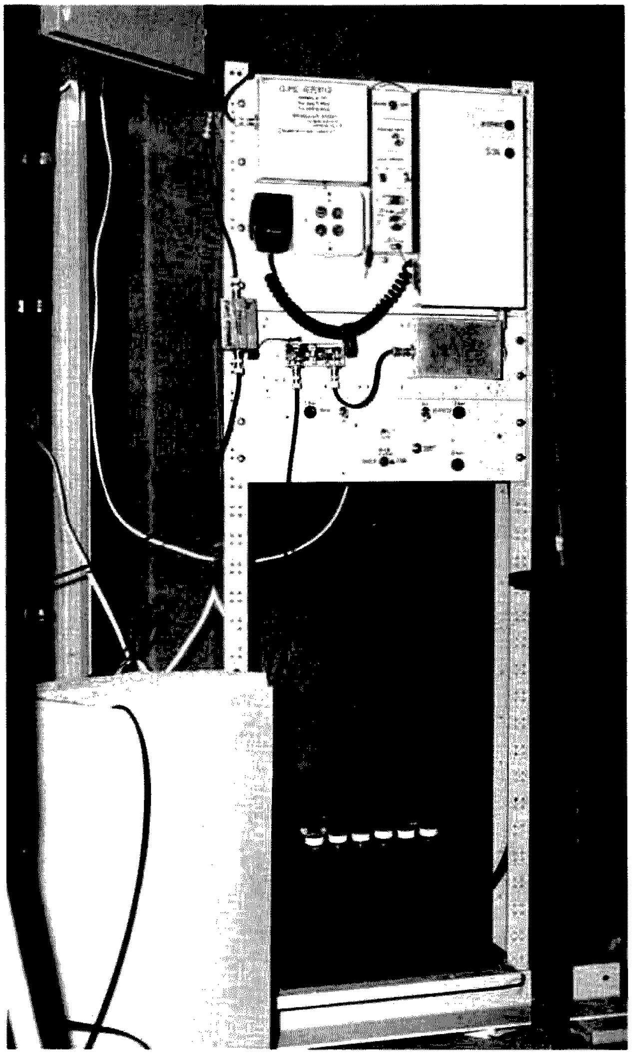
Repeaters in New Zealand

- - quite a few

Fred Johnson ZL2AMJ
15 Field Street
Upper Hutt, New Zealand



The Mount Climie FM repeater. Note the battery (below) and antenna filter box (left bottom).

FM repeaters hit ZL some five years ago, and since then have spread across the land. With a population of 4800 licensed amateurs, some 24 FM repeaters are now in operation, or about to become operational.

New Zealand is a land of mountains, lakes, rolling hills and open plains, and repeaters have helped to make VHF popular by overcoming terrain problems. The land in the region of Wellington, the capital, is all hills and valleys. People live in the valleys, and without repeaters VHF operation would be very limited for all but a few operators with hilltop sites.

The national radio amateur body is the New Zealand Association of Radio Transmitters (NZART), which has 75 branches. The licensing authority is the New Zealand Post Office (NZPO). NZART set up a committee some years ago to develop a band plan for the two meter band and to coordinate repeater development. In addition to the FM repeaters, some areas also have an AM repeater, and there is at least one two meter beacon station in each of the four ZL call districts.

ZL amateurs are fortunate in that the NZPO, while retaining the right to issue the license for a repeater, accepts to a large extent the views and requests of the VHF committee. So the amateurs have the responsible task of organizing their own band and repeater plan, ultimately seeking an NZPO license when all the various negotiations about sites, access, and other responsibilities have been ironed out and the need for the proposed repeater has been established. Most repeaters have been established to meet a Civil Defense or an Amateur Radio Emergency Corps requirement.

In the event of some disaster or emergency, the amateurs turn out to provide communications for the Search and Rescue Organization, the police, or Civil Defense authorities. Each NZART branch has an "E" series of callsigns allocated so that it is easy to tell when emergency traffic is using a repeater. For example, the Upper Hutt branch has the call series ZL2ELA to ZL2ELZ available. When E calls are heard on the repeater, normal amateur chitchat stops to allow the emergency traffic priority.

The relationship between New Zealand radio amateurs and the New Zealand Post Office is extremely good and in this we are very fortunate. New Zealand is one country where amateur radio is understood and supported by the authorities. In this regard, the IARU problems with WARC 1979 get both NZART and NZPO support.

The two meter band plan started out with four FM repeater channels and this was later extended to six. It can again be extended if found to be necessary. The following channels are in current use:

Channel A – 146.20/145.50
Channel B – 146.225/145.525
Channel C – 146.30/145.60
Channel D – 146.35/145.65
Channel E – 146.40/145.70
Channel F – 146.45/145.75

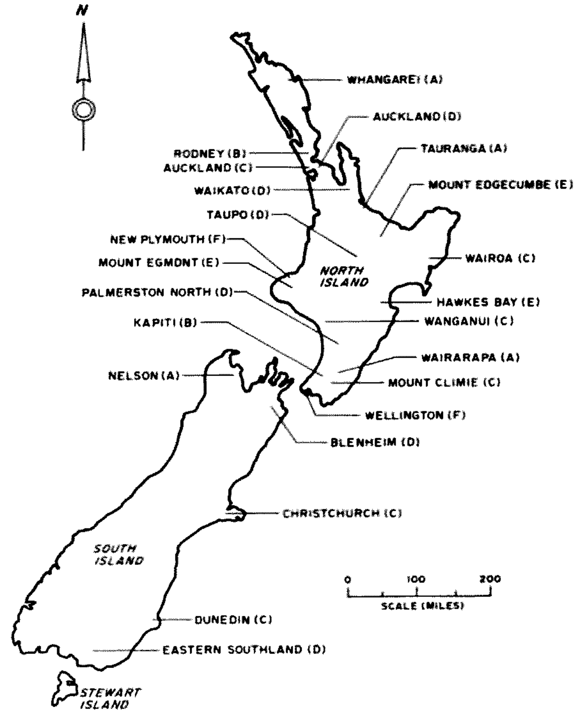
All repeaters are home-constructed, there being no off-the-shelf supply available. An enthusiast in one of the local branches of NZART usually constructs the repeater and finally becomes the "trustee" for the NZPO license.

All repeaters are open access; "closed" repeaters are not permitted. Carrier-operated entry is the rule. No tone-entry systems have been found to be necessary. The geographical spread and siting have made possible an almost exclusive channel allocation to each repeater. During hot summer weather, DX operation between repeater areas becomes possible. This is regarded more as fun than a nuisance.

The NZPO has not required a callsign or an identifier system for repeaters. All repeaters must be owned by a branch of NZART, and a member of that branch is the trustee for the repeater license. Repeaters cannot be owned by an individual. So the station using the repeater (i.e., the user callsign) and the trustee are responsible for the operational performance and operating discipline. In practice, this means that all repeater users have a responsibility to maintain a satisfactory standard of operating procedure. It seems to work out OK. "Repeater Rules" appear annually in the NZART Callbook. These reflect local operating practice:

1. The Trustees (as listed on the Post Office license) to have final responsibility for the repeater operation.
2. The repeater to be owned and maintained by the Branch.
3. The repeater to be open for use by all licensed amateurs.
4. Amateur Radio Emergency Corps and Civil Defense requirements in areas to have priority use over normal amateur traffic.
5. "Overs" to be kept short.
6. Breaks between "overs" to be frequent to let other users identify and call in.
7. Stations who can work together direct without using the repeater establish contact only and then change to some other channel.
8. Home station to home station contacts are discouraged.
9. The Radio Regulations to apply at all times, notwithstanding anything in these rules.
10. With the exception of mobiles, stations should not call a general CQ.
11. Stations using the repeater to identify when calling.
12. No one to be excluded from legitimate operation.
13. QSLs should be clearly marked "via repeater."
14. Contacts via the repeater will not be recognized for any contest or award.
15. A copy of these rules and the names of the Trustees to be posted on the Branch noticeboard.

The map shows the geographical layout and the channel allocations for the FM repeaters. Such a simple map cannot show the site and propagation considerations leading to the choice of each site. Recourse should be made to more detailed maps for this background.



Map of New Zealand showing location and channel of two meter band FM repeaters.

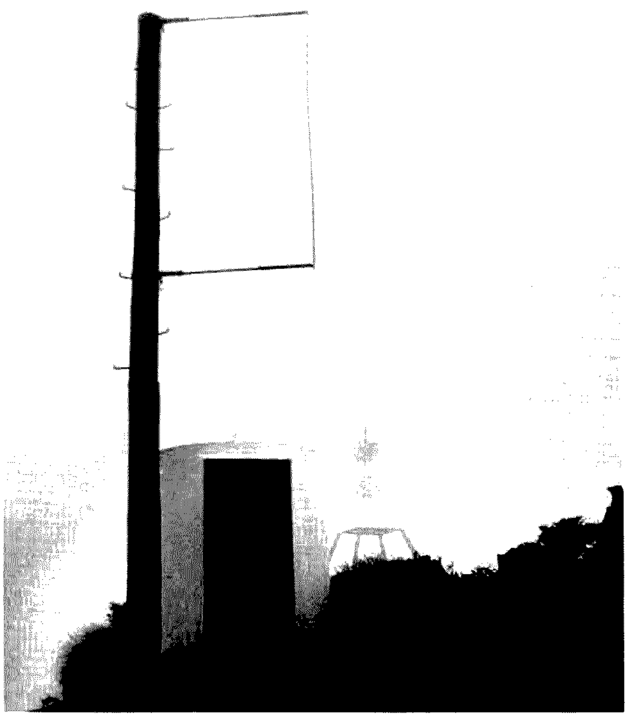
The highest repeater is on Mount Egmont, an 8620 foot high volcano. The repeater is sited about 3500 feet up the eastern slope of the mountain. One repeater (at New Plymouth) is destined to be sited on top of a 600 foot power station chimney. Most amateur repeaters live on someone else's premises, generally owned by the NZPO, the Broadcasting Council or the Civil Aviation authorities. One repeater which has its own hut is the Mount Climie repeater on "Channel Charlie," for which I am trustee.

Establishing "Charlie" has probably been typical of setting up a repeater anywhere: Negotiations for site, underground power cable to the site, a building, a pole, and so on, all had to be arranged. The hut was made by a concrete products firm, who said that they could deliver their product. When they heard that it was wanted 2823 feet up atop Mount Climie they still stuck to their word! A steep road gives good weather access, 11 miles from the Upper Hutt branch NZART clubrooms. The site is sometimes snowed in during winter.

A 200 yard long power cable trench was dug into the hilltop by branch members to get the 230 volt 50 Hz supply to feed the repeater. This is taken from a local microwave station.

The power supply authority had to erect an overhead line on poles to supply the microwave station. After some talking they agreed to provide an antenna pole for the repeater. This they delivered by helicopter and lowered into the hole – which they also dug!

Financing for the installation was obtained by selling kit sets for various branch construction projects. One such project was an FM transceiver kit known as the "Climie Transceiver." Some 110 of these were sold as kits and are in current use on various repeaters. Bulk buying of components and no labor or overhead charges enable branches to raise



The cloud-enshrouded Mount Climie FM repeater site. The trig station (behind) is for a spot height of 2823 feet. The antennas are in two identical sections – receive on top, transmit below. Each is a two half-wavelength collinear, fed with a balun and matching stub at the center. Steps on the wooden pole are an aid to climbing. The hut is reinforced concrete with a steel door.

money through kits.

The Upper Hutt branch of NZART is responsible for Civil Defense communications in the local area, and the cost of the power used at the repeater site has therefore been arranged to be met from the funds of other people! The branch is in the fortunate position of having a hilltop site and a repeater free of debt and free of running costs. It is serviced and maintained by voluntary effort. Contacts are possible at almost any time throughout the 24 hours because the channel is monitored by many people. It has been used for many emergencies and many exercises.

The "Channel Charlie" repeater runs off a float-charged 12 volt battery. It is all solid state and does not use mechanical relays or tubes. Several alarm circuits are fitted. One alarm shows up when the 230 volt ac main supply to the hut fails – to warn users that the equipment is running on the raw battery only. The other is an intruder alarm on the hut door – to advise unauthorized entry. The repeater can be shut down remotely by the trustee should this be necessary. Other facilities are in the process of experimental development.

So far, only the two meter band has been used for repeaters in New Zealand. The band extends 144 to 148 MHz. The 70 cm band plan is in the process of being polished and some groups are keen to see some repeaters established on that band. No crossband repeaters are envisaged and the linking of repeaters has not yet happened or been thought desirable.

Three grades of amateur operator certificate are in use in New Zealand. A Grade I certificate holder can use any amateur band. A Grade II certificate holder can use all bands except 40, 20, 15 and 10 meters; i.e., he can use 160, 80, 6, and all amateur frequencies above 144 MHz. A Grade III certificate holder is restricted to voice communication on bands above 144 MHz only.

There is one common theory and regulations examination set by the NZPO. Passing this examination alone can assure a Grade III certificate. Passing a Morse test at 12 words per minute in addition gets a Grade II certificate. With additional operating experience on 80 meters, a Grade I certificate can be obtained. The result is that the usual pattern is for the budding amateur to get a Grade III certificate first and later graduate to the other bands. This means that the new amateur has immediate access to VHF repeaters; this has contributed to extending the popularity of repeater operation. Grade III licensees are indicated by the "T" series of callsigns, e.g., ZL2TCU.

Visitors to New Zealand who hold an amateur license issued in certain overseas countries (including USA) can obtain a license to operate while in New Zealand. The "reciprocal licensing" arrangements vary from country to country. The address for enquiries is the Radio Section, New Zealand Post Office, Post Office Headquarters, Wellington, New Zealand. Several weeks notice should be allowed.

Visitors are welcome on all ZL repeaters. Operation on a repeater is an easy means to learn of local amateur club meetings and of other activities. Shack crawls and eyeball QSOs can soon eventuate once a strange or a new callsign appears on the repeater. See you in ZL? ■

Briefs

WR6ABE: over 700 users, 15 years on the air, extraordinary coverage throughout Southern California, one of the first big repeaters on the West Coast, but now a silent key, at least until early in the new year. K6OQK, the owner of the repeater, took it off the air in late October, hoping a cooling off period might end the QRM, obscenity and assorted garbage that's been wrecking the system for months. In the view of more than one reporter, ABE's problems grew from a small minority, plus its incredible coverage of the Los Angeles area. As Arny Gamson K6PXA, editor of *Scatter* (the journal of the Southern California Teleprinter Society) put it: "Is this a trend in ham radio where a very small percentage of jammers, drunks, and inconsiderates can ruin it for the majority?" We hope not.

The 20 meter jammer, heard for weeks and believed to be of Russian origin, is finally QRT. The incredible "buzz saw" noise was heard over a wide range of frequency, running from 40 through 15 meters here on the east coast. Despite international protest, the jammer persisted until early November. In fact, no one is really sure if the "buzz" was a jammer at all. W6PN, a former director of engineering for Radio Free Europe in Munich, is quoted as saying the noise was not a jammer. Instead, he says in the British *Short Wave Magazine*, "Its millisecond pulses, overmodulated at about 5 kHz, would be more suitable for propagation studies or some wide band operation."

Anti-antenna zoning harassment to hams and CBers is increasing throughout the country. In the latest case, an Illinois amateur has filed suit in an effort to prevent his city from forcing him to remove his 72 foot tower and antennas.

Walter Weber WA9FXG of Orchard Place IL first erected his tower last April. He was later told that he needed a building permit, after neighbors complained that the tower posed a danger to residents and interfered with their television reception.

When it was later decided that the tower violated the 35 foot building height limitation in his area, Weber sought a zoning variance. While the local Zoning Board recommended its approval, it was subsequently denied by the Orchard Place City Council who said they feared approval would set a precedent for other types of structures.

Weber's suit asks that the court declare the city's building code unconstitutional or declare that the height limitation does not apply to radio towers. He contends that defining a tower as a building is too broad and makes the building code vague. Weber added that many roof mounted television antennas exceed the height limitation.

There's help coming for amateurs who've run amuck of local zoning and interference laws. A national group of attorneys and judges, who are license holders in both the amateur and citizens band services, have formed the Personal Communications Foundation, a nonprofit, soon to be tax-exempt California corporation. Using thousands of their own dollars to get started, they plan to establish liaison and working committees to deal with issues like land-use restrictions, tower ordinances, deed restrictions, TVI-RFI and nuisance problems, and the related problems of jamming and other unlawful operating practices.

The cost is estimated to be about 80 thousand dollars for the first two years of organization, with the operation becoming self-supporting thereafter. The lawyers won't be making any money . . . to the contrary, the organizers are actually losing funds out of their own pockets to get PCF rolling. There is no affiliation with ARRL, or any other organization, although PCF is seeking advisory help. The organizers say if one dollar could be donated by one out of every three US and Canadian amateurs, within a year PCF could have a list of attorney liaisons available for publication.

According to one of PCF's founders, Los Angeles Attorney Jon Gallo WA6PTM, attorneys across the US have volunteered to open their files. That way, Gallo says, any individual could receive information from the foundation to help overcome communications-related legal difficulties. Local ordinances are being enacted not only banning towers over 35 feet and large antennas, but setting penalties for TVI-RFI as well!

PCF says it knows of such ordinances in 47 states, with at least five cases resulting in fines to licensed CBers for TVI-RFI. It's easy to see, PCF reasons, that amateur licensees are bound to be affected. The idea, says Gallo, is to cut the cost of defending hams and CBers by providing a national clearinghouse of legal information for attorneys. PCF emphasizes it will not actually defend anyone . . . but instead will try and cut the legal bills a tower fight or TVI case can bring. Stay tuned for further details.

The battle continues over operation of the Port Chester NY 34/94. A 15 signature petition demanding discontinuation of operation has been denied by WR2ABE trustee Michael Troy WA2TYV. Edward Zeiser WA2OQO apparently led the petition drive, claiming "unmitigated interference" to 146.34 and 146.94 simplex operation on Long Island. Zeiser addressed his petition to Stan Zak K2SJO, Hudson Division Director of ARRL. It turned out Zak had no connection with WR2ABE other than a wire line control point, given as a courtesy since he is local CD chief. In answer to the petition, WA2TYV suggested putting an end not to the Port Chester repeater, but instead to operation of 34 for simplex purposes. "Today's FM gear allows plenty of room for simplex, both above and below 146 MHz . . . while repeaters are restricted to the 146-148 MHz segment; no ham is forced to stay on 34 or 94 simplex."

In Ohio, Robert Scott W8SFK has printed a thousand protest letters, blasting the Ohio Repeater Council for assigning FM repeaters on 146.10 to 146.70 MHz. Pointing to gentlemen's agreements making 70 a national RTTY frequency, Scott terms the council's action "a flagrant violation of trust and a miscarriage of integrity." Scott argues that the very founding principles of the council are self-policing, common sense, good judgment, and a gentleman's agreement. According to Scott's letter of complaint, a new 10/70 near Findlay OH is disrupting simplex teletype in the entire northwestern quadrant of Ohio, the southern tier of Michigan, and northeastern Indiana, along with over 20 operators in greater Toledo. The Ohio Repeater Council has another point of view. Wrote George Hinds WB8JYR (the OARC Chairman), "Indianapolis, Cincinnati, East Liverpool, Cleveland and now Findlay have voice repeaters on 10/70 . . . The first three have been long established . . . The only operational RTTY repeater in the same region is Detroit on 22/82, not 10/70." Hinds went on to suggest there are many other frequencies on 2 meters for RTTY. "You have no more 'grandfather' rights to work simplex on the repeater segment of 146 MHz than did the fellows who long cherished 94 as a simplex frequency . . . Faced with the facts, not with dreams of the 'good old days' when 146-147 MHz were barren wastelands, OARC can no more sanctify 146.70 for you than we could keep repeaters off 94, 76, or 88, all of which at one time were simplex."

Icom East Distributor Kayla Bloom Hale W1EMV has resigned. Hale, a former editor of *73*, says she plans to retire to her Dublin NH home and do some writing, hamming, and relaxing. Kayla says she's tired of the grind, the never-ending shows, the thousands of miles of travel each year. On ham radio Hale is optimistic. "It's on the way up, just like the sunspot cycle . . . with a lot of CBers becoming disillusioned and turning to ham radio . . . I just hope they don't ruin it." In February of 1968, when Kayla became editor of *73*, she wrote some similar thoughts. "I was one of the 'save 11 meters' group way back when . . . since we lost the fight, I have not paid too much attention to what is going on on 27 MHz . . . Recently, after listening to the CB band, I was completely stunned by what I heard . . . Calls like, This is the 'Barefoot Boy' calling 'Yankee Pirate' . . . I feel certain these calls were not issued by the FCC . . . Amateur radio gave up 11 meters for this?" Things haven't changed much in 8 years, have they?

El Paso TX has a new repeater, designed for solar powered operation on top of North Mt. Franklin. Operation began October 9th on 146.10/70 MHz. The machine uses only about 11 mA on receive, about 500 mA transmit, with a power output of 2 to 3 Watts. Telemetry will be used to remotely monitor the repeater, using the output of the club's companion 28/88 machine. To conserve power and eliminate kerchunking, the COR is VOX operated. Still to be completed at press time was the machine's ID, telemetry, and control boards. An enclosure will also have to be built on the mountain to house the equipment. Except for Hallicrafters PC-18 boards, the entire repeater is home brew. That includes the cavities! Coverage is expected to be at least 100 miles in all directions with HT coverage of El Paso, Las Cruces and Alamagordo.
Reprinted from The Beam, *Bulletin of the Sun City Amateur Radio Club, El Paso TX.*

The denials persist, but Icom has indeed discontinued the much-loved IC-230 2m transceiver. Replacing the 230 is the IC-245, featuring continuous VXO tuning, 144-148 MHz, and programmable offsets. Priced at $499.95, it is seen as a prime competitor for the new Kenwood TR-7400A. Further Icom-Kenwood competition can be expected between the proven TS-700A and new Icom IC-211 base all-mode rig. Sales of the IC-22S continue to back up the dealers, with Engineering Specialties, a West Coast firm, offering the first commercial outboard encoder for the rig's diode matrix synthesizer (see New Product review this issue). We've also learned that Icom will release its first lowband radio early this year. A low power rig with digital readout, the Icom will cover 80-10 meters, will be super compact, and can be expected to be only the beginning HF-wise if well received.

FCC district offices are expected to begin using multiple choice comprehensive code exams in early January. The only possible holdup at press time was the government's contract for dupes (copies) of the newly recorded code exams. According to an FCC spokesman, the decision to switch to multiple choice was not based on a desire to make the code exams easier . . . but rather to make the tests fair. One official told *73* it was the Commission's belief many applicants were failing code exams due to nervousness, not a lack of code proficiency. Technician class applicants can expect 10 multiple choice questions for the 5

wpm test, General and Extra class applicants could see longer code questionnaires, but that was not certain at press time. Written exams, incidentally, break down to about 50% rules, operating procedures, and communications practices for the Novice, Technician, and General classes . . . with the remaining questions on radio principles and practices. The balance for Advanced and Extra is about 40-60, according to the same FCC spokesman.

The FCC continues to unlock the door on 1 x 2 callsigns. Latest batch covers N and X calls, with all Extra licensees eligible starting July 1977 (see FCC News Release).

John Lassig K5GFV has petitioned the FCC for amateur privileges on the 11m CB band. Lassig argues ham operation, under CB rules and regulations, would actually help FCC enforcement efforts and probably bring scores of CBers into ham ranks. (Lassig's petition appears elsewhere in this issue.)

At press time the crunch of new license applications had only begun to take effect in Gettysburg. With hundreds of Novice classes starting up all over the country this fall, it seems inevitable delays will be the result. Turn-around time, despite the expected crunch, was nothing short of unbelievable in mid-November. Using the special amateur radio post office box number 1020, and printing "Amateur Radio Novice Application" across the lower left of the envelope, brought written exams in less than 10 working days! It might help to write "Completed Amateur Exam Enclosed" on the return envelope as well. Again, that's FCC, PO Box 1020, Gettysburg PA 17325.
Thanks to Kettle Drums, *bulletin of the Kettle Moraine Radio Amateurs, Waukesha County WI.*

Confusion reigned among Technician class licensees during early November, as the FCC computer at Gettysburg fouled up those Novice class call reissues. The result: WN calls on repeaters and several cases of mistaken identity. The Technicians have been advised to use the WN calls until the computer errors are corrected. Novices, incidentally, received somewhat frightening letters from FCC . . . informing them that their tickets had been revoked and warning them not to use the WN prefixes. The second paragraph of the letters went on to inform them of their new WA-WB-WD calls . . . but we hear things got a little shaky upon opening those unexpected envelopes.

Clegg Communications, after going direct and eliminating the dealers last year, is now offering quantity price discounts on 2 meter and 220 MHz radios. Affected are the Mark 3 15 Watt 2 meter transceiver and FM-76 10 Watt 220 MHz transceiver. All units will carry full 90 day warranties, and Clegg says they will also supply Hustler, KLM, Phelps-Dodge antennas and KLM amplifiers at group prices. If your club is interested, contact Clegg at 208 Centerville Road, Lancaster PA 17603.

"Repeater DXer chastised by Canadian DOC" was the word at a recent session on the Ohio Area Repeater Council. It seems a formal complaint had been filed with the DOC by the Mansfield OH 34/94 system because of repeated interference to autopatch calls, search and rescue operation and normal QSOs by a Canadian station with a penchant for DXing and the resulting "keying up" of two or more repeaters simultaneously. It is understood that the offending station agreed, upon being contacted by the DOC, to cease and desist the practice. *Reprinted from the Lake Erie Amateur Radio Association* Repeater Newsletter, *October '76.*

Actual text of the Michigan State Law on scanners: "750.508. Any person who shall equip a vehicle with a radio receiving set that will receive

signals sent on frequencies assigned by the Federal Communications Commission for Police purposes, or use the same in this state, unless such vehicle is used or owned by a peace officer, or a bona fide amateur radio operator holding a Conditional, General, Advanced or Extra class amateur license issued by the Federal Communications Commission, without first securing a permit to do so from the Commission of the Michigan State Police upon such application as he may prescribe, shall be guilty of a misdemeanor, punishable by imprisonment in the county jail not more than one year or by a fine of not more than $500, or by both such fine and imprisonment in the discretion of the court."

You'll notice that no mention is made of any CB license, commercial license, or Novice or Technician grade license!

Reprinted from The Printed Circuit, *Bulletin of the Great Lakes Repeater Association, October '76.*

AMSAT, the Radio Amateur Satellite Corporation, now has over 2,500 members, according to the organization's annual report. That's a growth rate of 9%. Among the year's accomplishments: Canadian and US use of both OSCAR satellites for experiments in downed aircraft location, FCC authorization of ASCII on the satellites which enabled stations to remotely access a computer in Canada via OSCAR 7, University of Arizona and National Institute of Health researchers' experiments with the relay of electrocardiograms (EEGs) through OSCAR 7, and continued work on a prototype computer for use in onboard spacecraft control, with an eye on AMSAT Phase III. The Phase III spacecraft prototype is progressing with a December 1979 launch date projected. A second project, AMSAT-OSCAR D (A-O-D), is also underway with two transponders under construction. One will be two to ten meters while the other is a four Watt two to 70 cm unit developed by the Japan AMSAT Association (JAMSAT). Launch date for A-O-D is set for June 1977.

The Chicago FM Amateur Radio Club (CFMC) really scored on election day. Club efforts brought two television news stories, after the FMers provided communications for LEAP (Legal Elections in All Precincts) lawyers. WA9LRI reports participation from 30 amateurs who worked from 5 am through 9 pm using 2, 220, and 450 repeaters. CFMC dispatchers staffed LEAP offices, sending attorneys and their amateur communicators to investigate voter complaints throughout the city. Aside from the TV publicity, project LEAP brought radio PR and an article in the *Chicago Daily News.*

There are 15,500 licensed amateurs in Canada, and 1,400 of them have responded to a national poll on DOC proposals to restructure Canadian licensing. At issue is a non-code Experimenter class, and a 5 wpm Novice license. From the Canadian Amateur Radio Federation's poll results, it is apparent Canadian hams don't like the idea of non-code licensing. It was 63% against, 4% in favor, with 16% favoring an above 50 MHz Experimenter class. The idea of Novice licenses drew a much more positive response, with 55% of those questioned supporting it.

Our thanks to VE3CDC for passing along the CARF results.

Members of the Amateur Radio Society of India will soon have a new headquarters. The Indian government recently allotted the society a 4050 square foot tract of land in Delhi for a building and antenna farm. The land will be rented to the Society for a token fee. Members are at work planning the new facilities, which are expected to be operational early in 1977. Donations are being solicited. Contributions may be sent to: Amateur Radio Society of India, P.O. Box 534, New Delhi-1, India.

A VFO for Sidebanders

- - 5-5.5 MHz

Many transceivers today use some form of frequency synthesis or mixing process to derive a desired output frequency.

The mixing method is a very good one for several reasons, one of which is excellent frequency stability. For example, if an output frequency range of 28.0 to 28.5 MHz is required, it could be obtained by mixing 5 to 5.5 MHz and 33.5 MHz, the latter being furnished by a crystal oscillator. Using this method, the stability of the output frequency will be similar to that of the 5 MHz component, any drift which may occur in the crystal frequency being relatively small.

To derive a stable output frequency it only remains therefore to provide a source of 5 to 5.5 MHz signal which, when set to the required frequency, will continue to maintain that frequency and not be affected by the changing environmental conditions the oscillators may undergo during a communication period.

Reprinted from *Amateur Radio*, the Journal of the Wireless Institute of Australia, October, 1973.

Using this method of frequency production, the vfo can be allowed to run continuously, preferably 24 hours per day.

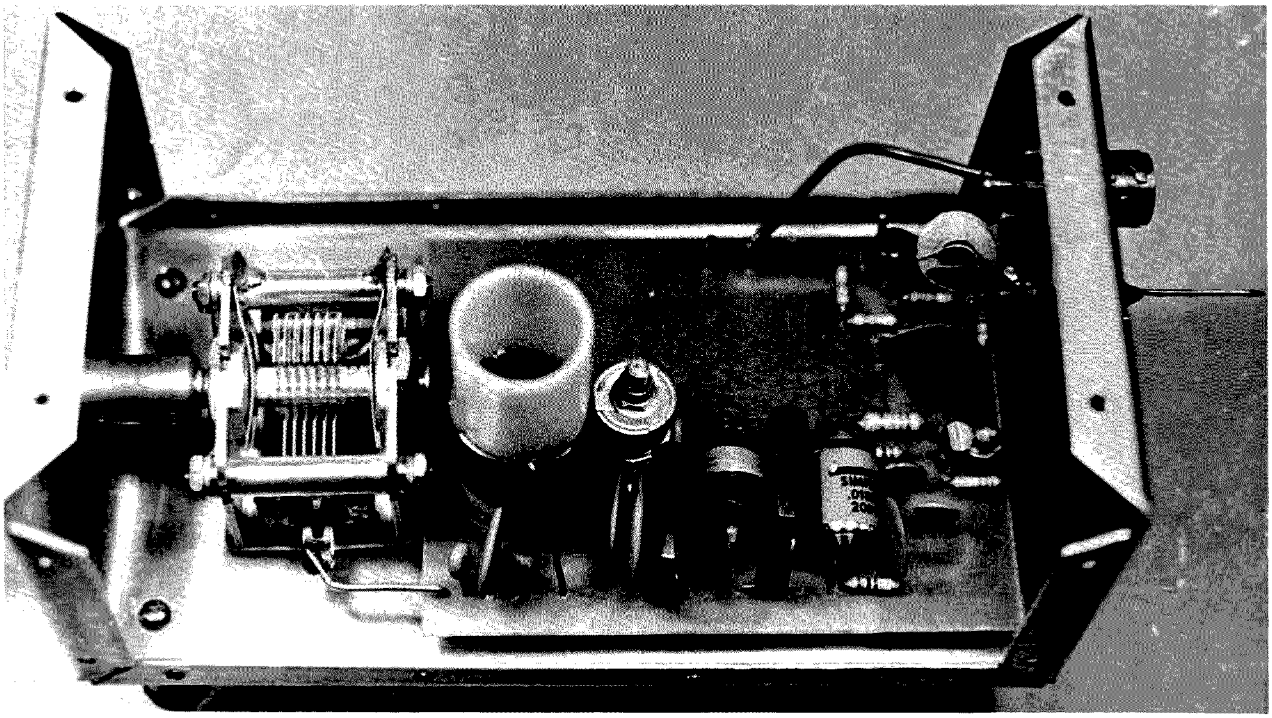
The vfo to be described here will provide such a variable source. Frequency range is 5.0 to 5.530 MHz. Stability is in the order of 2 parts per million per hour after warm-up. The frequency curve can be linearized using the split segments of the capacitor shown. Output voltage is 3 volts peak to peak sine wave into 1000 Ohms. Supply requirement is 12.6 volts at 25 mA. A supply voltage change of plus or minus 1 volt will result in a frequency change of about 1 Hz.

An FET is used as the maintaining device rather than a bi-polar transistor, in the interest of improved stability with changes in temperature.

The components of the oscillator and buffer amplifiers are laid out on an etched fiberglass board measuring 7 x 9 cm. Good mechanical stability can be secured using the form of construction shown, a U-shaped box and cover measuring 15 cm long, 6.5 cm high and 8.5 cm in width.

An ordinary ¼ inch solid coupler is used on the capacitor shaft inside the vfo box and a plastic rod should be used to connect the capacitor with the drive mechanism. A number 3 knitting needle is exactly ¼ inch in diameter.

The entire box is mounted on four 1/8 Whit. screws which are secured to the main exciter chassis through four



rubber grommets which provide some mechanical, electrical and thermal insulation. A considerable improvement in stability can be obtained by enclosing the vfo box in one inch thick polyfoam insulation. The coax from the vfo output socket provides the ground return for the supply.

The capacitors used at C4 and C5 are ceramic N750 type for frequency drift compensation. The values shown were arrived at after some experimentation with temperature versus frequency. It will probably be necessary to find the exact amount of capacitance by similar experiments. If the frequency increases with temperature, there is too much negative capacitance; if the frequency decreases with increasing temperature, there is too little. Use C2 to restore the correct frequency range. Remember to give the components time to reach room temperature after soldering before taking frequency measurements. If a very stable vfo is required, you must be prepared to spend some time in determining the exact amount of capacitance required.

The author spent considerable time experimenting with various types of coil formers and fixed capacitors in the tuned circuit. A good quality ceramic coil former is ideal of course, but here in Melbourne there appears to be no ready supply. The former finally used was a ¾ inch Wynne (teflon).

An output waveform which is distorted may be traced to an FET which has too much gain. As 2N3819s have considerable parameter spread, it may be necessary to try a few FETs in order to obtain a clean output waveform. ■

Practical Solar Cell Power

- - great for remote repeaters

Sometimes you find yourself surprised at what you can do when you think hard about a problem. A good example is energy conservation (a popular subject these days), and techniques developed for WR2ACA.

Most of the time there is no shortage of power because the wind blows often enough and hard enough to provide what is necessary. Nevertheless, there are times when power must be rationed carefully in advance by the design of the equipment. Conditions of energy availability can be divided into three categories:

(1) Abundant wind, generators working, full battery charge.

(2) Average, moderate winds with normal repeater activity. Repeater draws more power than generators deliver, but idle periods allow catch-up.

(3) No wind at all or failure of the charging system for extended periods.

If the first condition persisted all the time, we could install electric heaters in the place and have no problems. Power consumption of the equipment would be of little consequence.

The second condition represents normal operation as we experience it 90% of the time at WR2ACA. Here energy must be budgeted carefully so that idling drain stays low enough to allow recharging of the batteries as rapidly as possible.

Depending on the battery charge level at the start of condition (3), normal operation will continue until the charge is reduced to the minimum required to keep the system "alive" to assure self-recovery at the end of the energy drought (assuming no back-up system or failure of same). In order to provide continuous operation of vital systems (such as the control and intrusion alarm systems), and to make sure there is enough energy to excite the wind generator when the wind does return, the batteries must never be allowed to go completely dead. When you reach this point, it becomes crucial to conserve every mA in the vital systems.

Various pieces of equipment that are used in different time cycles can be considered from different points of view in terms of power drain requirements. For example, if the transmitter is to deliver 50 Watts of output, at least 50 Watts of power must be supplied to it even if it is 100% efficient. For a system voltage of 13 volts and a 50% efficient transmitter (good) that operates for a continuous two hours per day, 15.4 Ampere-hours are consumed per day.

On the other hand, a receiver that draws 100 mA but runs for 24 hours per day consumes 2.4 Ampere-hours over the same period. The receiver draws only 1.3% as much current as the transmitter, but it consumes 15.6% as much energy per day because it runs 12 times as long each day. With this time ratio (or "duty cycle"), a current drain increase of 1 mA in the receiver is equivalent to a 12 mA increase in the transmitter. Thus it is 12 times as important to find a way to conserve current in the receiver as in the transmitter.

If the receiver is only one of several in the system and there is a fair amount of logic drain involved, it is easy to rival the energy requirements of the transmitter in normal operating cycles.

So, we conclude that receiver drain is important. In emergencies, even all but one receiver could be shut off to save current for the systems critical to the recovery of the repeater, but we start to take reliability risks since failure of that receiver alone would cause total loss of remote control capability. But we could take that risk if necessary, saving energy to sustain the other systems: intrusion alarm, wind-generator tachometer, touchtone decoder, logic memory, battery monitors and active measuring equipment.

If we provide for system self-recovery and take the chance, we could even shut off the last receiver. This could be done automatically when the system is on its last legs and you would lose voluntary remote control. The receiver(s) would be automatically reactivated when the voltage came up due to renewed wind or if the intrusion alarm tripped.

That saves the drain of all receivers, but unless you have been careful in the assignment of mA in the design of the vital systems, you might not be able to hang on long enough after such a drastic measure.

So, let's categorize the equipment in terms of current drain and systems role:

(1) High-drain low duty cycle with little chance of improvement (transmitters, loudspeaker amplifiers, remote motor drives, etc.).

(2) Medium-drain circuits that draw current only when the repeater is activated but not transmitting (receivers, transmitter synthesizer circuits, etc.).

(3) Potentially low-drain circuits on vital systems needed for control, protection and self-recovery.

The last category represents the majority of circuits in which a mA here and there rapidly adds up to surprising levels. If the total power drain of all these circuits can

Reprinted from *The Link*, Bulletin of the Buffalo Amateur Radio Repeater Association, Inc., May, 1975.

be held to a small fraction of the self-discharge current level of the batteries, we have done good work.

Nickel cadmium batteries of the vented type can hold most of their charge after standing for a year, but the batteries we have to work with are of questionable history. It is probably optimistic to expect self-discharge to take longer than 6 months. If that is the case, a 440 Amp-hour bank drains itself at a constant 100 mA. The current capacity is less, but ultimately we would like a capacity of at least 400 A-H.

You can see that the current levels involved are still comparable to the self-discharge rate – hence further effort in conserving current is worthwhile.

In the present WR2ACA repeater, current drain is about 8½ Amperes at full repeat operation, about 500 mA activated but not keyed, and about 120 mA idling. The idling current can be broken down into a 450 MHz receiver drawing about 45 mA, a 2m receiver with preamp at about 55 mA, and about 20 mA for the remaining systems.

It is the idling current that provides the greatest opportunity for improvement; hence in it lies the thrust of this article. It is true that the system as is could be left alone and operate satisfactorily. However, if two or more additional receivers were added to the system, the drain could grow rapidly. Thus, with expansion in mind, our techniques could stand some improvement.

A technique used in the new 2m receiver has solved the problem, at least for the receivers. It is based on a simple idea; turn them off for most of the time!

When the repeater is idling, the receiver serves only one purpose: to detect the presence of a control signal. Suppose we turn the receiver off 9 seconds out of every 10. During the one second it is on, the receiver determines whether or not a signal is present. If one is, the squelch circuit holds the receiver on until such time as the signal again disappears and the squelch closes again. As long as no signal appears, the receiver is on only 10% of the time; hence it draws only 10% of normal drain.

This technique was utilized on the old ACA receivers, but it wasn't effective because the only way to put them in this mode was by remote control. In order to get the system back to normal, it is necessary to hold at least 10 seconds of carrier to make sure you have covered one of the "on" periods, then transmit the correct control codes. A 10 second wait is too long so it wasn't practical to idle the receivers this way for normal operation.

The idea was still attractive anyway because two receivers operating in this way, if normally consuming 100 mA, would only draw 10 mA (or possibly less by using a lower duty cycle).

If you could shorten the "off" time to a tolerable waiting period, it would be necessary to reduce the "on" time by the same proportion to save the same current. The limiting factor boils down to the shortest possible time you can turn the receiver on and reliably detect a signal.

There are many practical pitfalls that must be circumvented to make a receiver turn on rapidly. Assuming that these can be overcome, what are the limiting factors dictated on theoretical grounds?

The answer is easy for the case of a strong signal but somewhat more involved if weak-signal detection is a requirement. For linking receivers it can safely be assumed that the signal is always full quieting since the transmitter location power and signal path is known and fixed.

In this case we only have to have power applied long enough for a signal to propagate from the antenna terminal to the point of detection. Most of this delay is in the i-f filter that determines the receiver's selectivity. FM filters I have measured show delays of 200 to 300 microseconds. If we allow another millisecond for the detector to operate, the "on" time is only 1.3 milliseconds. To save 90% of the power, the receiver can be set to sample every 13 milliseconds! In everyday operation a delay as long as 150 milliseconds is hardly noticeable because it takes many receiver squelch circuits that long to operate; hence, if the sampling period is increased to 130 milliseconds, the receiver current drain is only 1% of its normal value!

The limiting factor in a repeater receiver, as opposed to a linking receiver, depends on how weak a signal you would like to detect. In the noisy signal case, the receiver must be left on for a period of time to make a statistical average of signal power to noise power. This process is called integration.

All weak-signal detection schemes can be boiled down to filtering and integration combinations of one sort or another. Disregarding the filtering aspects for the moment, the sensitivity afforded by an integration system is proportional to the integration time. (There's that nasty word *time* again!) Simply stated, this means that the receiver "on" time must be longer for a weak signal than a strong one, forcing us to choose the "best" compromise between sensitivity, sample interval and the reduction of current. An FM signal having enough noise on it to make copy difficult can be detected in 10 to 20 milliseconds. If we assume the 20 millisecond figure, the receiver can be turned on 5 times per second and still save 90% of its current drain!

After a series of hair-tearing sessions on the ACA receiver, a sensitivity of about 0.1 uV for a reliable squelch break could be achieved. To allow for temperature variations (and Murphy), the squelch setting was tightened to about 0.15 uV. A minimum of 3 samples per second was chosen as a tolerable objective. The result is that the standby drain is reduced from about 45 mA with a preamp to a very desirable 3 mA.

When a signal is received during one of the samples, the squelch breaks and locks the receiver on for the duration of the signal. If the sender subsequently transmits a turn-on code (whistle or touchtone) to activate the repeater, the receiver is locked on for the entire time the repeater stays in the active state. Thus you only have to "wait" for 1/3 second when you turn the repeater on; after that, the receiver becomes as normal as any other 4 channel repeater receiver.

None of this is really new; duty cycling techniques are as old as technology itself. They have been applied in communications to hand-held transceivers with their tiny batteries, an obvious application. But applied to our battery-operated repeater system, it works wonders. If 100 mA of continuous receiver drain was tolerable before, we could accommodate 33 repeater receivers or nearly 300 link receivers (or a mix of the two)!

Of course it is possible to design lower current receivers, too. At the present time this approach would eliminate the integrated circuit limiter discriminators and require more costly transistors. Thus it would increase the number of parts, and certainly increase the difficulty of design.

Pulsing is easier. We could go further – design a low current receiver and *then* pulse it for even greater savings.

Then again, do we really need more than 300 receivers? ■

A Simple RC Substitution Box

-- using a matrix

Those amateurs who are constantly engaged in circuit experimentation or development work have probably purchased or built elaborate R and C substitution boxes. Such substitution boxes greatly simplify the problem of finding just the right component value to use to optimize circuit performance for any desired condition (maximum gain, bandwidth, stability, etc.). For those amateurs who just occasionally build some accessory circuits, substitution boxes would also be very useful when a given circuit doesn't work exactly as it should or when one wants to determine if an available component will do in place of a specified value. Unfortunately, cheap RC substitution boxes don't buy you too much. The increments in which they cover RC values are usually too large and calibration can be poor. One can substitute potentiometers for fixed resistors in a circuit, but their calibration is poor and one has to constantly check the value of a setting with an ohmmeter. The result of all this is that most occasional circuit builders end up soldering in components of a fixed value into a circuit and by trial and error arrive at a successful result or a hopeless jungle of tack-soldered components.

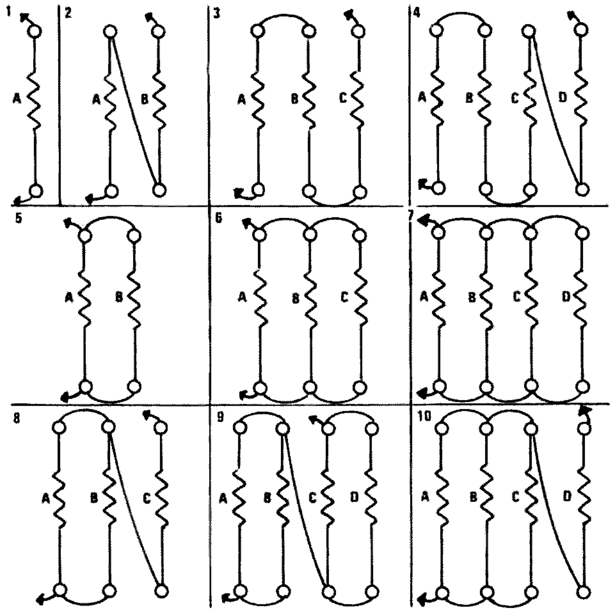

Fig. 1. Interconnection diagrams for four resistors in substitution matrix.

The simple matrix described in this article can solve those problems for the occasional circuit builder at a very low cost and still achieve accurate results.

Most RC substitution boxes, whether they be for resistance or capacitance substitution, make use of switches to select components of various values. However, another approach would be to take a fixed number of components (R or C) of different values and hook them up in as many ways as possible (series, parallel, series/parallel, etc.) to obtain a succession of different overall values. However, how many fixed values should be chosen to keep the circuit complexity within bounds, and what should their individual values be both to obtain a good overall substitution range and have a smooth progression of resultant substitution values?

We'll let a computer solve some of the latter questions, and it's not surprising that a computer comes up with a "binary" type answer. We'll use resistors to demonstrate the idea, but it is equally applicable to capacitors, as explained later. Take four components (resistors) of value 10, 20, 40 and 80 Ohms and let's see how many different ways they can be interconnected. The interconnection possibilities are illustrated in Fig. 1, starting with the simple use of one of the resistors alone and then various series and series/parallel connections. There is nothing new about these circuits, but what is interesting is what happens if one tries all the circuit possibilities and then arranges the resultant values that can be achieved in order. The result, as shown in Table 1, is a wide, smooth range of resultant values going from 5 Ohms to 150 Ohms. Four *properly* chosen resistors have resulted in the equivalent of almost 40 different resistor values progressing in very even steps over a 30 to 1 range!

Table 1 is, in fact, a universal value table. It shows resistance values of 5 to 150 Ohms being achieved by four individual resistors of 10, 20, 40 and 80 Ohms. But, it can be scaled up or down to achieve different ranges with other, similarly ordered values of individual resistors. For instance, the following would be the range of values achievable with the resistors shown:

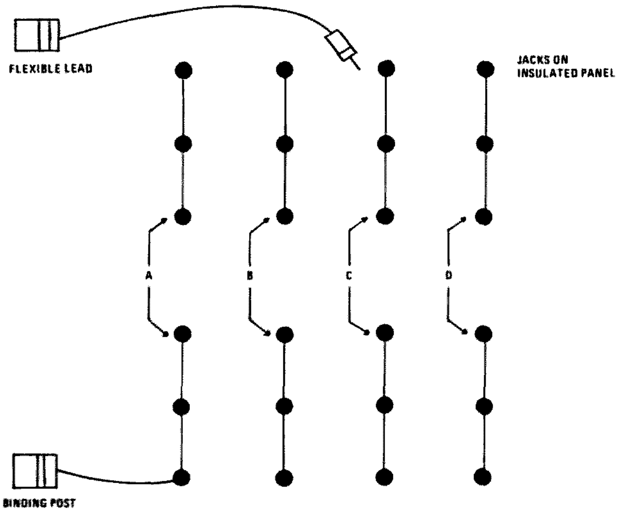

Fig. 2. Matrix panel suitable for either resistor or capacitor usage.

Ohms	Circuit	A	B	C	D
5	7	10	20	40	80
5.6	6	10	20	40	
6.2	6	10	20	80	
6.8	5	10	20		
7.5	6	10	40	80	
8.0	5	10	40		
9.0	5	10	80		
10	1	10			
11	6	20	40	80	
13	5	20	40		
16	5	20	80		
20	1	20			
22	9	10	80	20	40
24	9	10	40	20	80
26	8	20	80	10	
27	5	40	80		
28	8	10	40	20	
29	8	10	80	20	
30	2	10	20		
33	9	10	20	40	80
36	8	40	80	10	
40	1	40			
45	10	10	20	80	40
46	8	40	80	20	
48	8	10	20	40	
50	2	10	40		
56	8	20	80	40	
60	2	20	40		
70	3	10	20	40	
80	1	80			
90	2	10	80		
91	8	20	40	80	
100	2	20	80		
110	3	10	20	80	
120	2	40	80		
130	3	10	40	80	
140	3	20	40	80	
150	4	10	20	40	80

Table 1. Circuit numbers refer to those shown in Fig. 1.

0.5 to 15 Ohms – use 1, 2, 4 and 8 Ohm resistors. 50 to 1500 Ohms – use 100, 200, 400 and 800 Ohm resistors. 0.5k to 15k Ohms – use 1k, 2k, 4k and 8k Ohm resistors. 15k to 150k Ohm – use 10k, 20k, 40k and 80k Ohm resistors. 150k to 1.5 M Ohm – use 100k, 200k, 400k and 800k Ohm resistors.

The resultant values can be checked by anyone using the usual series/parallel resistor formulas for any of the circuits shown in Fig. 1. A more practical question might be how to implement the idea in a simple, reliable form. One could, of course, devise a special switch to achieve all the hookups shown in Fig. 1. Some manufacturers capitalized on this idea. However, a simple home brew way to arrange the four resistors in any of the circuits shown in Fig. 1 is to use a simple plug and jack switch matrix as shown in Fig. 2.

Four columns of six plugs each are used with the individual resistors inserted in the positions shown. The lower "output" terminal is fixed at the bottom of the "A" column. The upper "output" terminal is connected via a flexible wire so it can reach any of the plugs on the upper row of the field. By moving the latter jack wire, plus the use of a few jumper wires between columns, any of the circuits of Fig. 1 can be wired. With a little practice, one quickly develops a system to go from one circuit configuration to the next.

The matrix of Fig. 2 can be built on any insulating material (perforated board stock or plexiglass), using inexpensive non-insulated plugs and jacks. One could permanently solder in the resistors, but if they are made "plug-in," the same matrix can be used for different resistance ranges by plugging in different sets of four resistors. The matrix board is a neat and orderly way of interconnecting the four resistors. But if one had to do it, they could also be interconnected using simple jumper leads by keeping Fig. 1 and Table 1 handy for reference.

Standard value resistors do not come in all the desired values (4k and 8k, for instance). Choose the closest available values to those shown (3.9 and 8.2k, for instance), but measure them once with a good ohmmeter. Usually resistance values, unlike capacitor values, are well within the manufacturers' stated tolerance. Standard, inexpensive 10% tolerance resistors should work fine for most circuit work. But, again, check them first before relying upon them. The tolerances can either build up or cancel out in the various series/parallel circuits. The power rating of the resistors used depends upon the circuit applications intended. For most low level transistor circuits, 1 or 2 Watt resistors will certainly suffice. If one obtains the four resistors for the 0.5 to 15 Ohm range, they should be of the 10 Watt size since they will most likely be used for power supply or audio power amplifier circuit applications.

What about using the matrix for capacitor substitution? Of course, series and parallel resistor circuits have their equivalent in parallel and series capacitor circuits. The circuits of Fig. 1 and Table 1 can be used if one remembers the equivalent circuits. For instance, for 150 Ohms Table 1 calls for the use of circuit 4 in Fig. 1, which is all resistors in series. If one wanted 150 pF (using individual capacitors of 10, 20, 40 and 80 pF), the equivalent capacitor circuit is used – connect all capacitors in parallel. For 5 Ohms, Table 1 uses circuit 7 and connects all resistors in parallel. For 5 pF, connect all capacitors in series. For 30 Ohms, Table 1 uses circuit 9 or AB parallel in series with CD parallel. For 30 pF, use AB in series and then parallel with CD in series. Table 1 can be scaled up or down for capacitors the same as it can be for resistors. The total range for each set of four capacitors will remain a 30 to 1 range: 5 to 150 pF

for fixed capacitors of 10, 20, 40 and 80 pF, 0.1 to 3 uF for fixed capacitors of 0.2, 0.4, 0.8 and 1.6 uF, etc.

Unfortunately, capacitors, and especially electrolytic types, vary widely from their marked value. Tolerances of up to -20 and +40 percent for electrolytics are common. One can build a substitution matrix using disc ceramic or mylar capacitors and rely upon the capacitor values to be close enough to their nominal values for general substitution work. In practice, this means a substitution matrix going up to about 1 uF maximum. Beyond this value, when one has to use electrolytic capacitors to build the substitution matrix, it is imperative that the actual capacitor values be measured if the substitution matrix is to have any reasonable accuracy.

This article has described a simple individual R or C substitution matrix. If the resistors and/or capacitor sets are made for plug-in use, the matrix of Fig. 2 can be used for either type of substitution as required by an individual circuit. With a few matrix boards and several sets of resistor and capacitor plug-in sets, a handful of components can be used to replace *several hundred* for substitution, testing and experimental purposes.

Finally, how about RC combinations such as time constant circuits, low pass and high pass filters? These can also be built for various values and frequencies by combining R and C elements on one or more matrix boards. The variety of values here is so broad that it is impossible to define any table for them. However, by using the known R and C values for the individual RC substitution boards and standard formulas, one can easily develop a duplicatable set of response configurations usable for a wide variety of circuit experimentation. ■

The Compactron Audio Driver

- - three tubes in one

Although transistors are definitely taking over in many areas of electronics, there is still a place in tube-type equipment of modern design for compactrons. The compactron I used in a recently constructed modulator was the 6K11-6Q11. This is a triple-triode, which has two sections that are equivalent to a 12AX7. The remaining section is very similar to a 6C4. So by merely "lifting" the values from the *Radio Amateur's Handbook* or other such source, we can build the complete audio preamp-driver in a single envelope. Fig. 1 shows the schematic I used. I fed a pair of 6L6s, but any pair of pentodes in AB1 up to 6146s could be driven.

Because of the very high gain in such a small area, more than normal care with such things as lead dress must be used to avoid feedback that might lead to oscillation. I found it necessary to include an rf filter at the microphone input, and I shielded the filter with a 35 mm film can. This prevents rf on the microphone cable from getting back into the amplifier.

This audio section would go quite well with K1CLL's rig described in *73*, June 1966, page 18. ■

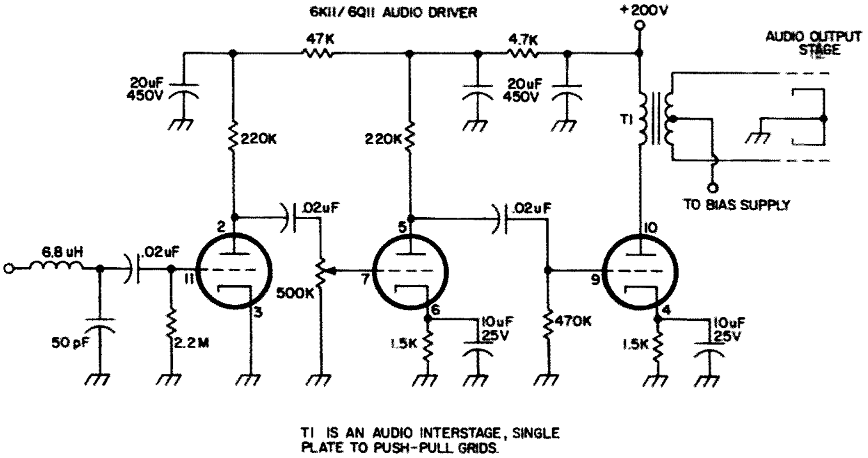

Fig. 1. 6K11/6Q11 audio driver.

Social Events

WAUKESHA WI
JAN 22

The 5th annual Midwinter Swapfest of the West Allis Radio Amateur Club will be Saturday, January 22, 1977 starting at 8 am at the Waukesha County Expo Center. Tickets: $1.50 advanced, $2.00 at door. Reserved tables by advanced reservation only – $1.50 per 4 ft. table. Non-reserved tables first come, first served. Talk-in on 146.52 MHz. Directions: I-94 to Waukesha Co. F, south to FT, west to Expo. For information and tickets write: WARAC, P.O. Box 1072, Milwaukee WI 53201.

FORT WAYNE IN
JAN 23

The annual Fort Wayne Winter Hamfest will be held at Shiloh Hall north of Fort Wayne, Indiana on January 23, 1977. Hours are from 9 pm to 4 pm local time, and early parking is available. This yearly event is sponsored by the Allen County Amateur Radio Technical Society (AC-ARTS). Admission is $1.50 by advanced ticket, or $2.00 at the door. Table space is available for vendors at $1.00 per half-table (about four feet). For more information or advanced tickets and table reservations (held until 9:30 am), write to Hamfest Chairman, AC-ARTS, Inc., P.O. Box 342, Fort Wayne, Indiana 46801.

CORPUS CHRISTI TX
FEB 4-6

The Texas VHF-FM Society will hold its winter meeting at the Holiday Inn, Emrald Beach, 1102 S. Shoreline, Corpus Christi, Texas, on February 4, 5, 6, 1977. For further information contact: James Linthacum W5LCN, 1802 Daly, Corpus Christi, Texas 78412.

MANSFIELD OH
FEB 6

The Mansfield Ohio Mid Winter Hamfest Auction will be held February 6, 1977 at the Richland County Fairgrounds, Mansfield, Ohio. Prizes, flea market, auction – large heated building. Doors open 8 am. Talk-in 146.34/.94 and .52/.52. Tickets $1.50 in advance, $2.00 at the door. Contact Harry Frierhen K8JPF, 120 Homewood, Mansfield, Ohio 44906 or phone (419) 529-2801 or (419) 524-1441.

TRAVERSE CITY MI
FEB 12

The Cherryland Amateur Radio Club will hold its 4th annual Swap 'n Shop Saturday, February 12, from 9 am to 4 pm at the Northwestern Michigan College in Traverse City. A donation of $1 will include a chance on all prizes. There will be plenty of free display tables for whatever you may wish to bring in electronic equipment and parts. Everyone is welcome and a turnout of over 300 hams and experimenters is expected from all over Michigan. For more information please contact Bill Mader WA8WWM, at (616) 326-6392 or Box 2, Empire AFS, Michigan 49630.

WHEATON IL
FEB 13

The Wheaton Community Radio Amateurs will hold their 15th Annual Midwinter Swap & Shop on Sunday, February 13, 1977, from 8 am to 5 pm, at the DuPage County Fairgrounds on Manchester Road (near County Farm Road) on the west side of Wheaton, Illinois. Some tables will be provided, but bring your own if possible. WCRA invites anyone with an interest in buying or selling new or used electronic equipment to attend this hamfest, which will be inside large, heated buildings at the fairgrounds. Advance tickets (available until February 1) are $1.50, and tickets at the door are $2.00. Write Oran Hiscox WB9JJL, Ticket Chairman, Wheaton Community Radio Amateurs, P.O. Box QSL, Wheaton IL 60187. Commercial exhibitors should write Paul Sexauer W9JTO, at the same address.

GRIFFITH IN
FEB 19

The Lake County Amateur Radio Club's 24th annual banquet is Saturday, February 19 at 6 pm, at the Griffith Knights of Columbus Hall, 1400 South Broad Street, Griffith, Indiana. All the delicious home-cooked food you can eat, wine fountain, entertainment, guest speakers, special awards, door prizes, cash raffles and a dance band after. Tickets are $7.50 each: no door purchase. Write (prior to Feb. 3) to Herbert S. Brier W9AD (W9EGQ), 409 S. 14th Street, Chesterton IN 46304.

VIENNA VA
FEB 20

The Vienna Wireless Society annual Winterfest will be held at the Vienna Community Center. Indoor tables, sales, technical sessions, prizes and food. 8 am to 5 pm. Drawing at 3:30 pm. Admission is $3.00; tables $5.00. Information write Box 418, Vienna VA 22180.

NORWOOD MA
FEB 25

The Norwood Amateur Radio Club will be holding its annual auction on Friday evening at 7:30 pm on February 25, 1977 at the Norwood (Mass.) V.F.W. Post on Dean Street, Norwood. This is just off U.S. Route 1 south.

DAVENPORT IA
FEB 27

The annual Davenport Radio Amateur Club Hamfest will be held Sunday, February 27, 1977 at the Masonic Temple in Davenport, Iowa. Admission is $1.50 advance – $2.00 at the door. Talk-in on 28/88 and 52. Refreshments and tables are available. For info and tickets send SASE to Dick Lane WAØGXC, 116 Park Avenue, So. Eldridge IA 52748.

LAPORTE IN
FEB 27

The LaPorte, Indiana ARC will hold its Winter Hamfest on the 27th of February, 1977, beginning at 8 am (Chicago time) at the LaPorte Civic Auditorium. Good food, plenty of free tables, 50 miles east of Chicago. Talk-in on 01-61 and 94, donation $2 at the gate. Information from LPARC, PO Box 30, LaPorte IN 46350.

Repeater Update

73 will soon be publishing updates to our *Repeater Atlas*. All repeater owners are urged to contact us if their systems have changed from the original listings, or if they have put new machines on the air. Our listings are being computerized, which will make it a piece of cake to keep you informed about the repeater situation. But we can't do it without your help, so get cracking!

Please return completed questionnaire to:

REPEATER ATLAS 73 Inc., Peterborough, New Hampshire 03458

☐ I don't even have a repeater going.
☐ Repeater is private, don't list it.
☐ Repeater is private, list for reference only.
☐ Repeater is open (at least to transients).

I have built the "accu-memory" authored by J. M. Garrett WB4VVF described in the August, 1975, issue of *QST*. I also have a "Hal MKB-1" Morse keyboard. For some time while operating one or the other of these two fine units, I have thought how convenient it would be to combine the two pieces of equipment. My problem is how to load the "accu-memory" with the keyboard and how to use it as a buffer to store and release the code on command or automatically. Maybe some of our more knowledgeable readers would be able to help.

I have an old Dumont transicom VHF FM unit that was taken out of service at the Fairborn OH Fire Dept. It was given to me by a friend who works there. The model (FCC type #) is 5814-D, Serial #140, and the chassis # is 158030. This is the number I got off the back end of the chassis. The problem: I can't seem to locate a schematic or any other information on the unit. I want to be able to convert it to the 144-148 MHz band. So, could anyone in the country please help me in locating a schematic and other info on the Dumont unit? Any help would be appreciated and I'm willing to pay for the help!

The Junk Box as an Art Form

-- new use for blown capacitors

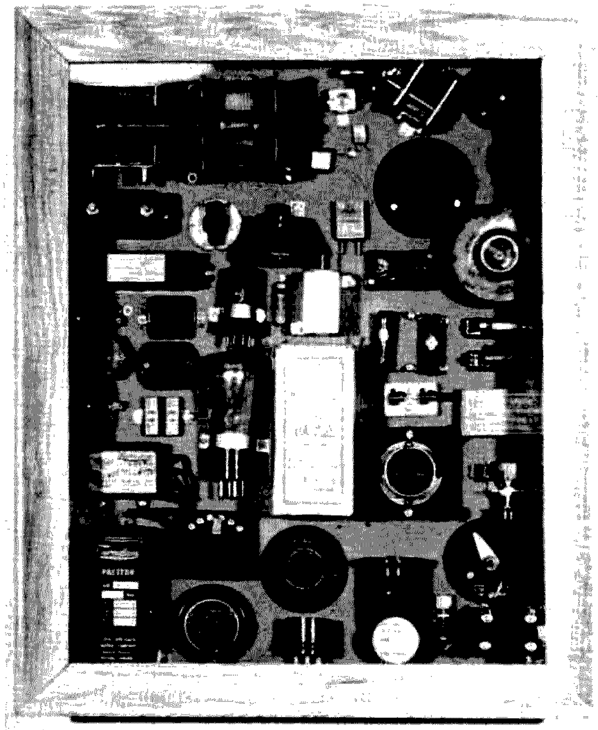
How would you like to have an attractive station decoration and at the same time preserve your antique parts? Well, it's possible by building a shadow box as shown in the photograph.

Over the years one finds that his storehouse of antique parts gradually disappears through loss and breakage. Putting them on a shelf is a real dust catcher, and, in addition, you just don't have the room; besides, a mess of old parts is not attractive.

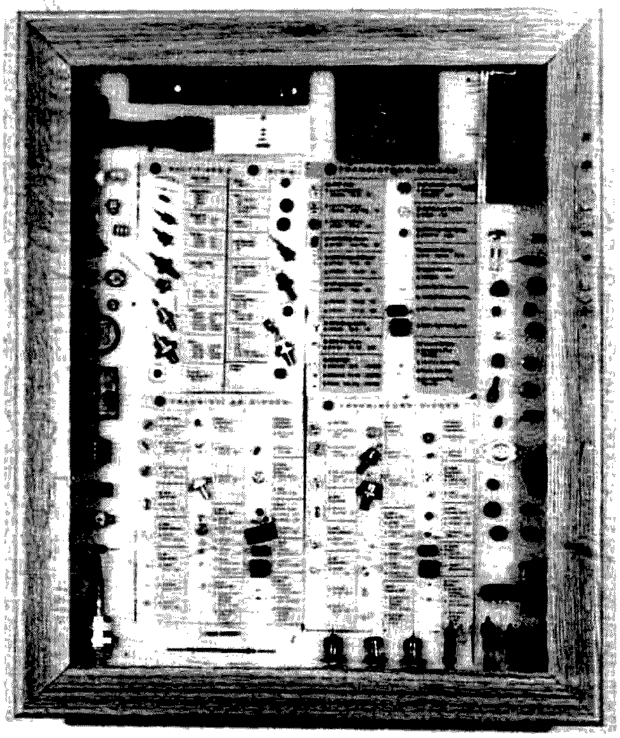
Some of the rare gems in this box are wireless specialty condensers, a Faradon, old dials, a rheostat, an old tube box with the tube removed and mounted next to the box, old variable condensers, a crystal detector, a Thordason audio transformer, and many others. Your junk box is a gold mine.

Select the parts you want to preserve and then try different arrangements. When you have the arrangement you want, measure the width, height and depth you will need and make your box to size.

You can buy the material, the frame, felt, etc., at the local discount store. Use standard sizes of frames. You will find the natural oak frames are best, but others



Shadow box with antique components.



A companion piece that shows circuit boards, integrated circuits, transistors, and the history of miniaturization.

lend themselves quite well. The total cost of my whole project was \$2.75 plus about three hours of interesting labor.

Select frames that have about a ¼" lip on the back so that you can set the shadow box over them and then screw it to the frame. Be sure to apply glue to the glass, as the objective is to make the whole box dust and airproof so the parts will be good for life. Seal the edges to the frame after you have screwed the box to the frame.

The frames I used were 14" x 21" and were just right for these parts. Make the shadow box out of ¼ inch plywood as it is easy to work with and does not split when you nail at the edges. Before you nail, apply a small amount of glue on the edges. Make the sides first and square them up and let set overnight. Then lay on a piece of plywood and mark the back and saw. Then apply glue and nail. Now paint the box inside and out, and after it's dry, glue a piece of red or green felt to the inside – bottom only.

There is not a set procedure for mounting – you will have to improvise as you go. Most all of these parts were mounted with small screws. Some components mounted easily after soldering on small lips, etc. Very lightweight brass sheet was used for clamps, etc. The ¼" plywood gives you plenty of bite to mount any medium sized part. Be sure that the screws don't go through the back and scratch up your wall or table.

This makes a wonderful decoration for the wall of your ham shack – just put screw eyes in the top at each edge and hang it on the wall. This same idea lends itself to a lot of things around the ham shack and perhaps you can even make the XYL happy by making her a shadow box for memorabilia she might like to display. ■

The Mod Squad Goes 220

-- pub serv receiver for pocket 220

There is the slogan "use it or lose it," which we have all heard in connection with the 220 MHz amateur band.

Here in Southern California, I took this to heart and, lo and behold, that band is in my opinion the best band of all! That band now has more activity and more repeaters than 2 meters does in some parts of the country, with many hundred users in the Los Angeles area alone.

The one problem we have is the lack of available equipment. So far only one handheld transceiver has come out for this band and, as of this writing, it is not yet being delivered. We have need for something small, light and not too expensive. What I (with the help of proddings and suggestions of Bill Duhaime WA6NTW) have developed is a sensitive 12 channel (that's correct – *12 channel*) pocket receiver that is an ideal back-up receiver, duplex receiver, and in my case, the remote end of an auto burglar alarm system.

This receiver is a converted MR-2 receiver (Photos 1 and 2). It was designed to cover up to 170 MHz, has built-in nicad batteries, comes complete with charger and is available for about $80 from several sources, including me. When conversion is complete, the receiver has a sensitivity of better than .5 microvolt, and is free from intermod and image problems. The receiver has three filters incorporated in its design, with two in the 10.7 MHz i-f and one in the 455 kHz i-f, and is, in sort, a darn good receiver. It has 20 transistors, including five stages of limiting and a very fast squelch which gives no squelch tail to speak of.

Photos by Herbert Dick

The Conversion

The first step of the conversion is to modify the local oscillator multiplier. The crystal oscillator stays the same, as the crystal will be in range of the normal tuning of oscillator coil T8. Referring to Fig. 1, and the diagram supplied with the radio,

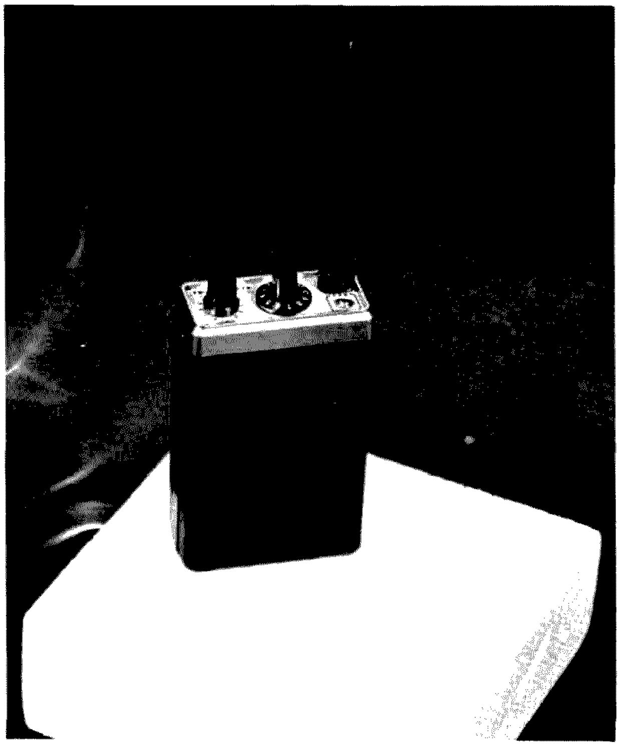

Photo 1.

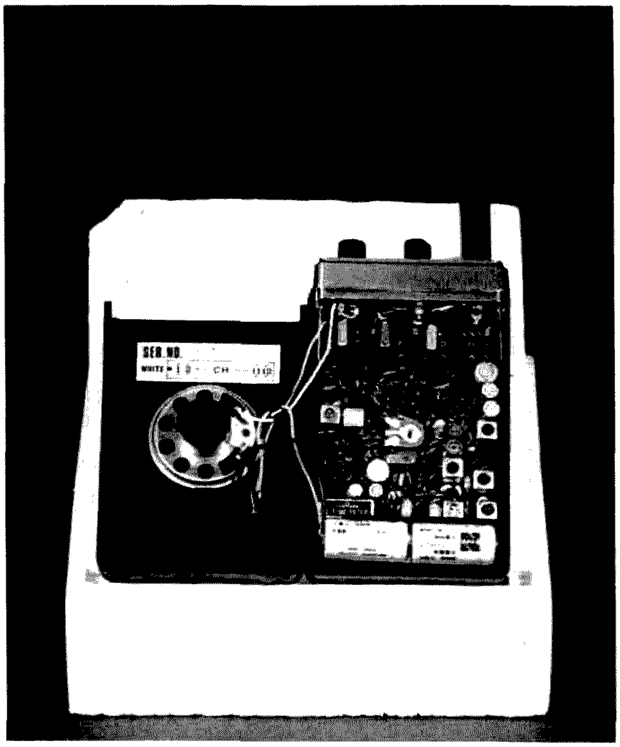

Photo 2.

locate C2. This capacitor is OK as is, but if you wish to use the crystal from a Midland 13-509 receiver, as I did, this capacitor may be removed, making the crystals interchangeable. T8 will now tune with the slug near the top of the coil form. The crystal frequency will be the same as the Midland 13-509, which is the desired 220 Mhz frequency minus 10.7 MHz, divided by 4 (3rd overtone series resonance into 20 pF load capacitance). The next step is to modify T4. This stage is made to quadruple by replacing the 7 pF capacitor (C28) with a 5 pF capacitor and removing one turn from the secondary of the coil.

The method of modifying this, and all following coils, is as follows: Remove solder from can tabs and *carefully* work the can off coil. Be very careful since the coil form will break easily if forced (see Photo 3). As the can pulls clear, note the ferrite cup that will probably stay in the can. Do not lose or break this as it is an important part of the coil. After placing can and cup aside, remove solder from all five pins of the coil form and gently remove this form from the PC board. Next place coil in a soft-jawed vise and gently hold in place (Photo 4). Locate the secondary winding (the three pin side) and using a needle and small soldering iron, gently lift the wire from left end pin (bottom view with 3 pin side facing you). Carefully remove one turn and reconnect wire after removing insulating varnish. Reassemble the coil form by installing back on PC board in the reverse order as removed. This coil will now tune to the 212 MHz range needed and the receiver will now hear a strong 220 MHz signal if one is provided.

The next step is to modify the input tuned circuit by replacing the 7 pF capacitor (C4) with a 3 pF, C1 with a 10 pF capacitor and remove one turn from the secondary winding of T1. This winding is lifted from the same pin as it was in the local oscillator multiplier. Next, the output circuit of this same stage (rf Amp) must be changed. Remove the same one turn from secondary as in the other two coils and replace the 7 pF capacitor (C6) with a 5 pF capacitor. Now go to the mixer input coil (T3) and in a like manner remove one turn from its primary and replace its 7 pF tuning capacitor (C8) with a 5 pF capacitor. The conversion is now complete with the exception of tuning.

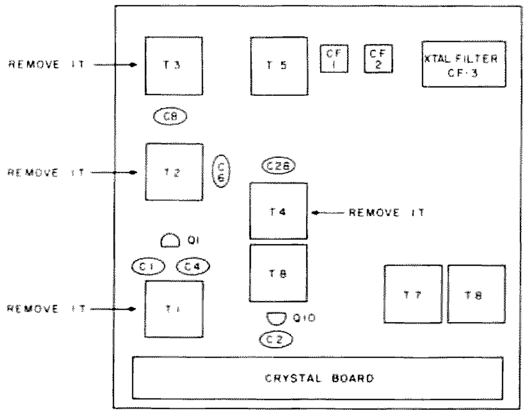

Fig. 1.

Tuning

Place a crystal in a position and select it with the channel switch. With a strong signal source and an attenuator (rotatable beam and distant transmitter), tune the oscillator and multiplier coils for maximum received signal. The tuning of the multiplier is quite critical and should be done with care for maximum sensitivity. Note: The slugs are very brittle and a proper fitting tuning tool (even if home brew) must be used or the slug *will* break. Always attenuate signal until noise is heard and tune for maximum quieting. Following the same procedure, likewise tune antenna coil T1, amplifier output coil T2, and mixer input coil T3. If all is working properly, the MR2 will now work better on the 220 MHz band then many popular rigs work on two meters. I should mention that this receiver works very well on two meters, before the conversion, and is a very good buy for that purpose alone. ■

Double Sideband: Something New?

- - one for voice, one for SSTV

One of the modes of operation permitted by the FCC for SSTV is the operation on ISB (Independent Sideband). In this mode of operation the voice signals are transmitted on one sideband while at the same time the associated SSTV signal is transmitted on the other sideband. At the present time there are no commercial amateur radio transmitters on the market that have this mode of emission available. Several amateurs have been active on ISB using circuits they have developed for SSB transmitters that use the filter method of sideband generation as described in the SSTV Handbook.[1] My transmitter is a Hallicrafters HT-37 which generates its SSB signal by the phasing method of sideband generation. I decided to try and see if I could figure out a way to get ISB from my HT-37 for my SSTV transmissions. This article presents the results of this effort and shows how I was able to generate ISB from the HT-37 by using an external unit and a very minor modification to the HT-37 transmitter.

The phasing method of sideband generation was first used when SSB appeared in the ham bands. A well-known circuit that has been used by many builders of SSB gear was presented in the G.E. Ham News[2] back in 1950. That circuit was used to develop the SSB transmitter made from the old Command transmitters[3,4] and forms the guidelines for the ISB unit in this article. I first considered just making another exciter like the one in the HT-37, but the unavailability of the proper components led me back to the old standard phasing circuit design used many years ago.

In this ISB system the HT-37 is used to generate one of the two sidebands and an external exciter is used to generate the other sideband. The output of the external unit is fed to the same mixer as that used in the HT-37 SSB generator. Due to the method of heterodyning in the HT-37 to obtain the proper sideband for that particular frequency, it is necessary to manually select the desired complementary sideband when using the external ISB exciter. The particular SSB used for each band is identified from a chart on the front panel of the ISB exciter. The design and operation of phasing type SSB exciters are very well described in the referenced articles and will not be reviewed in this article.

Construction

The unit shown in the photographs was constructed on two separate chassis, one stacked on top of the other. The overall size of the finished exciter is 3½" wide by 7½" high by 12" deep. It is housed in a surplus aircraft equipment cabinet. The top chassis contains all the electronics, and the bottom chassis has the power supply. The power cord and the output connector are at the rear. The front panel contains

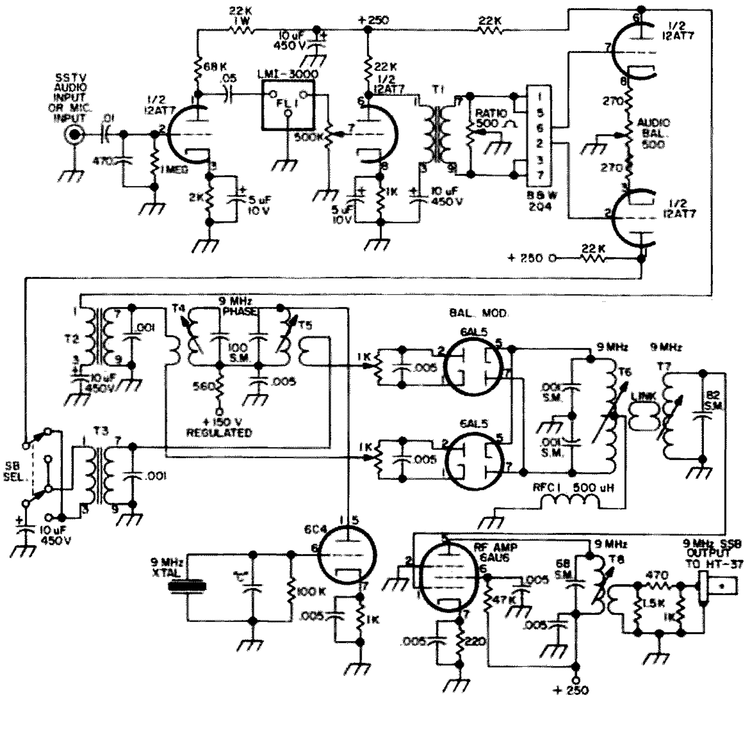

Fig. 1. ISB exciter for HT-37. T1, T2, T3 = Lionel #GH1203-2-H 22k to 600Ω. FL1 = UTC LMI-3000 low pass filter.

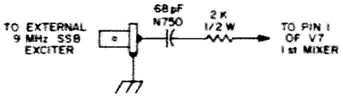

Fig. 2. HT-37 modification.

the audio input connector and gain control, the sideband selector switch, power switch and pilot light. I used a commercial low pass audio filter in the speech amplifier section to limit the upper frequency response to 3 kHz. This filter may be deleted and a filter using TV width coils substituted as shown in the referenced articles. I had an LMI-3000 unit in my junk box, so that is what I used. The other filter will work equally well in this circuit. T1-T3 are surplus Lionel audio transformers of the type used in the reference 3 article. A good substitute would be the Lafayette AR-151. T4 and T5 were made from surplus SCR-522 coil forms. They are 3/8" diameter and have 12 turns of number 20 wire with a three turn link at the cold end. They are padded with a silver mica capacitor to resonate at 9 MHz with the slug about halfway in the coil. T6 is a slug-tuned coil of 5/16" diameter with 8 turns, center-tapped. The link is two turns wound around the center of the coil. The wire on T6 is also number 20 enameled. The link wire is made from single strand plastic insulated number 20 enameled. The T7 and T8 are small ¼" diameter coil forms, slug-tuned and wound with 20 turns of number 30 enameled wire. The link is three turns on the cold end. The coil is padded with silver mica condensers to resonate at 9 MHz with the slug at midrange.

The power supply should provide 250 volts at 90 mA and a regulated 150 volt output at 10 mA. The 80 mF of filtering seems to be sufficient for this unit to provide good dc to the audio and rf circuits.

The modifications to the HT-37 were surprisingly simple. The schematic diagram of the HT-37 shows that the output of the internal 9 MHz exciter is fed to a mixer V7. I decided to feed my external exciter into that same mixer grid. A hole was drilled in the front panel midway between the driver tune knob and the band selector knob. A type BNC connector was installed in this hole. The 68 pF capacitor and the 2k resistor are then wired from this connector to pin 1 of V7. You will find that locating the connector at this position on the front panel of the HT-37 makes for very short leads from the connector to the tube socket. This is the only modification required to the HT-37.

For proper operation of the ISB system, the 9 MHz oscillator in the external exciter must be zero beat with the 9 MHz oscillator in the HT-37 exciter. I accomplished this by monitoring the output of the HT-37 9 MHz signal via the newly installed BNC connector on the transmitter front panel, on a communications receiver (Hammarlund Super Pro, 1945 vintage). The output from the external 9 MHz oscillator was also picked up by the receiver and the detected beat note observed. A padding capacitor was installed across the crystal to pull it down to zero beat with the HT-37 exciter oscillator. The external 9 MHz oscillator was initially several hundred Hz higher than the HT-37 9 MHz oscillator. These two oscillators must be zero beat to assure that the recovered sideband will contain the proper frequency information. If they are not zero beat, and the receiver is tuned so that the picture information has the correct frequency information, then the accompanying voice will not have the proper sound. The adjustment of the 9 MHz ISB exciter is just like any other phasing type SSB exciter and is fully described in detail in reference 4; therefore it will not be repeated here.

Operation

The output of the external ISB exciter is connected to the HT-37 by a 3 foot piece of RG58A/U coax. The SSB system at K7YZZ includes a second hand Heathkit Warrior linear using four 811As in grounded grid. The system must be adjusted so that you now share that power between the two sidebands. This means that you cannot run the same SSB power on ISB as when you operate in SSB. My linear normally runs 200 mA on meter peaks when on SSB. This means that I must not run over 200 mA on ISB, or I will be over-driving that linear. I then have to divide this power between the two sidebands like this: The SSTV signal is fed to the microphone input of the HT-37 and the level adjusted so that the linear is running only around 100 mA. Then the microphone is connected to the external exciter and the gain adjusted so that on speech peaks the linear power amplifier meter moves from the SSTV level of 100 mA up to 200 mA. This means that the two independent sidebands are now sharing the power, driving my amplifier in an acceptable manner. If you wish to run more SSTV power, then increase the gain on the HT-37, but you also

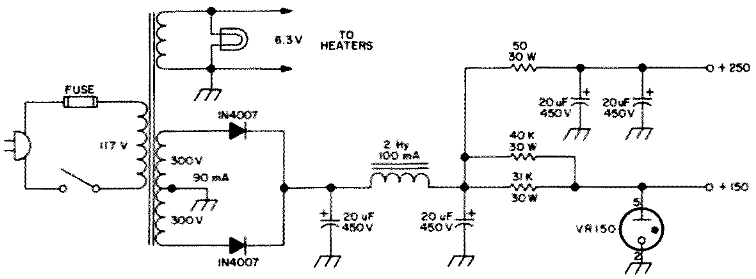

Fig. 3. Power supply.

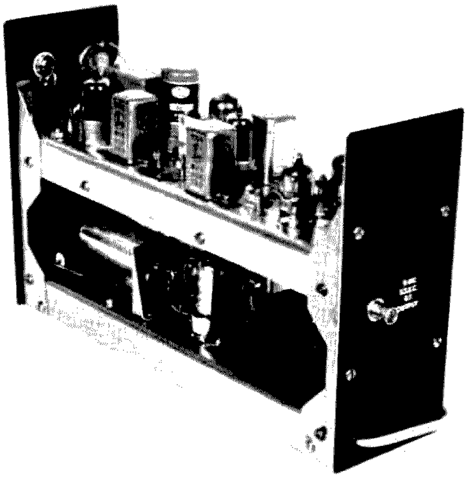

must reduce the gain on the external ISB exciter so that the voice peaks will not exceed the power amplifier ratings.

I think probably one of the strangest things you will encounter will be the sudden realization that you are being heard at the same time you are being seen. Usually SSTV is a series of pictures followed by voice transmissions. Here suddenly you are being seen and heard at the same time, and it is quite a surprise the first time you work a station that can receive ISB SSTV transmissions. I have not gotten used to that sensation yet.

The unit described in this article has been in service for about two years and seems to hold its adjustments very well. The unwanted sideband suppression is of course not as good as a filter rig, but it is entirely acceptable for a phasing type SSB exciter. I would be pleased to hear from any other builders who are working with phasing type ISB exciters for SSTV. I wish to thank "Gervie" W7FEN, who assisted me with many on-the-air ISB tests. ■

Carbonize Your Crystal

-- a return to the carbon mike

Surplus FM units are still a good investment for the ham who wants to get on the FM bands and still have good quality equipment. For less than $100 you can get a tube-type rig which can give you 25 W output and receiver sensitivity better than a microvolt. Also, these tube-type rigs are not as susceptible to intermod and desense problems as some transistor rigs.

One problem with these radios is that they require the use of a raspy sounding carbon microphone. It would be nice to use one of the mikes from around the shack, but that means buying an amplifier to get the low level output from a ceramic, crystal or dynamic mike up to the level that is put out by a carbon mike. Then there is the problem of getting power to the preamp and/or finding someplace to mount it.

A carbon microphone is basically a resistor whose resistance is varied when a signal (voice) is applied to its input. This same definition could be applied to a transistor. So we can replace the carbon mike with a transistor which will give us enough gain to use a lower output microphone. First it is necessary to bias the transistor to "look" like a carbon mike. To do this we adjust the bias to the transistor so that the key down voltage across the transistor is the same as the key down voltage across the carbon mike.

Fig. 1 shows a typical carbon mike input network from a Motorola PA-8664, 30 W transmitter. This can be converted into a Thevenin (dc) equivalent circuit as shown in Fig. 2, or the equivalent can be determined experimentally as shown in Fig. 3. To make the measurements, momentarily key the transmitter and measure the voltage across the carbon mike button as shown in Fig. 3(a). Open circuit the path through the carbon mike and again key the transmitter as in Fig. 3(b). This time you are measuring the Thevenin voltage. Now, exchange the voltmeter for a milliammeter and measure the current drawn key down. The Thevenin resistance can be calculated by dividing the voltage in volts by the current in mA to give the resistance in K Ohms. This combination, as shown in Fig. 3(c), is a dc equivalent that allows you to experiment with various surplus transistors without having to key up your transmitter continually until you strike the right combination to bias the transistor. This equivalent can be set up using a bench power supply or a combination of batteries. It only requires a few mA, so almost anything will do.

Once the equivalent is set up you must choose what kind of mike you wish to use. If it is a low impedance dynamic mike, you will want to use a low impedance input

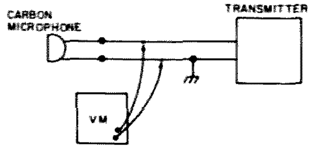

Fig. 3(a).

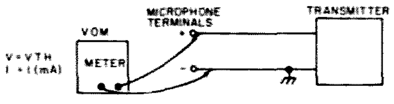

Fig. 3(b).

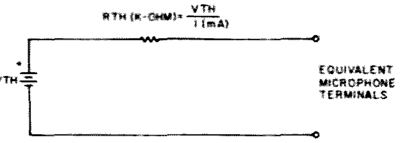

Fig. 3(c).

transistor (BJT) to get the best power transfer. For a high impedance mike, an FET will be required. I used 2N3396s for the BJTs (5/$1.00 from Poly Paks), and 2N3819s for the FETs (2/$1.00, Poly Paks). But any NPN BJT with a beta greater than 150 should work and most n-channel FETs should, too. Just be sure they can stand the open circuit voltage of the mike circuit.

The circuit for high impedance microphones is shown in Fig. 4. The FET requires a dc path from the gate to ground which is provided by the mike itself. While adjusting the bias you may want to put a resistor from gate to ground rather than a microphone. Any value from 50k to several megs should do. R_X is a 1 or 2k pot. Simply turn on the power and adjust the pot until the meter reads the same voltage as you measured across the carbon mike in Fig. 3. As an alternate method, adjust R_X until the voltage between the drain and source terminals of the FET are about one third of V_{th}. After R_X has been set, measure its value and replace it with the nearest fixed value resistor. This circuit has provided satisfactory gain, but if more should be needed it could be obtained by bypassing R_X with a small 5 uF capacitor.

The circuit for low impedance microphones is shown in Fig. 5. R_X is a high resistance pot such as one megohm. The mike does not need to be in place for the bias to be set. Simply turn on the power and adjust R_X so that the voltmeter reads the voltage in Fig. 3, or you can set it again to about one third of V_{th}. Once this is done, replace the pot with a fixed resistor of the same value and you are ready to go. You can get more gain from this circuit by dividing R_X into two resistors and bypassing the junction of these two to ground. But, again, this was not found to be necessary.

Once the mike circuits are biased, it is a simple matter to fit them into a microphone case if desired. This method is preferred but the preamp could be mounted in the control head or even on the chassis of the rig. I have used these circuits for many years and have gotten good audio reports.

Another possible use for the high impedance circuit is a quick and easy coupling circuit for a repeater which would allow taking the audio from the receiver before the audio output stage, so that you could adjust the monitor level without fear of affecting the repeat level. Also, since it has a high input impedance, you could use it for mixing several sources into one transmitter without loading effects as sources are switched on and off (see Fig. 6). ■

How Does Sideband Really Stack Up?

-- the SSB solution?

More and more, our VHF amateur frequencies are being eyed by commercial interests such as business and government, and personal communications needs continue to escalate. We should have had fair warning several years ago when thousands of surplus FM units were dumped on the market when overcrowded conditions forced splitting 50 kHz channels into 25 kHz ones.

Needless to say, CB Class E on 220 MHz is not the *only* threat to our VHF and UHF allocations. With fire, police, government, VHF marine, common carrier, mobile telephone, industrial, and military users all looking for new frequencies, VHF is overloaded in many metropolitan areas. The fact is that the FCC has opened a *new band* around 960 MHz (*practically microwaves*!), just to accommodate some of these stations![1]

Another fact is that there have been numerous attacks recently on portions of our bands. Class E CB, for instance, was originally proposed for two meters. Emergency medical services included several channels in the 432 MHz band in a shotgun request for frequencies for paramedical support requirements. Offshore drilling interests have successfully gotten a docket for temporary use of 432 MHz for HIRAN, a radiolocation system. This is similar to the "shared" use we suffer on 220 MHz (HIRAN is on a "non-interference" basis), where military radar takes the lion's share! There has even been a plan to replace the six meter band with TV channel 1.[2]

As you can see, "Use it or Lose it" is *not* a dead motto!

I've never been one for throwing up my hands and saying, "Oh well, you can't fight city hall or big business." Amateur radio has thrived because of brave souls who have challenged the status quo by engaging in "impossible" pursuits using "inadequate" resources. Oscars 6 and 7 are ample proof of this. You'll look long and hard to find a "professional" or government satellite that cost only $60,000. The first Oscars cost even LESS!

Back when mobile radio was being studied and it took six Amps just to light up the receiver, industrial engineers studied the strengths and weaknesses of AM, FM, and SSB.[3] AM came out third overall because of its interference problems (heterodynes), susceptibility to ignition noise, higher current drain due to the modulator, and difficulty in obtaining and maintaining a high level of modulation. FM was the ultimate winner because its limiting effect made it less prone to ignition interference, its capture effect reduced co-channel interference, its modulation requirements were simple, and "hands off" operation was characteristic because of positive squelch action and relative immunity to degradation due to off frequency operation (±1 kHz). General design considerations and economy were factors in the adoption of FM.

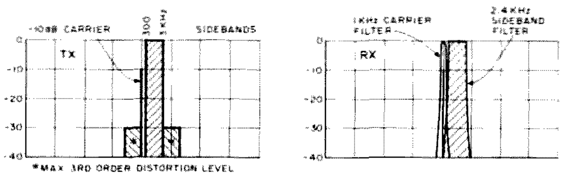

Fig. 1. Phase locked sideband. Note: Receiver sensitivity to the carrier is greater than to the sidebands, due to the 1 kHz filter. This somewhat makes up for the -10 dB level.

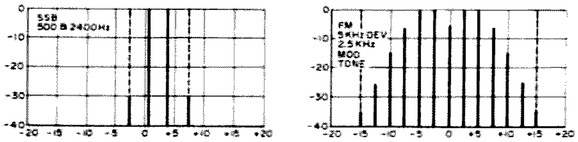

Fig. 2. Occupied bandwidth.

But technology has advanced some since this decision was made, and perhaps it is time to re-evaluate the situation in light of ever expanding needs.

TYPICAL USES

The Small Fleet

Quite a bit of VHF use by small businesses is limited to one or two base stations talking to three or more mobiles. Trucking firms, farmers, security patrols, and road services are a few of the types of users that come to mind.

Normally a 25 or 100 Watt mobile serviced by a 100 Watt base station is used. Converting to SSB would require little *operational* change other than occasional touch-up of a clarifier to net mobiles to the base station frequency. As this can be done with a simple VXO circuit adjusting a few Hz, no operational difficulty exists.

Certainly the tripling of available channels, greater range, and lower current drain far outweigh the inconvenience of touching up a clarifier a few times each day!

Repeater Uses

Many users are tied one way or another to a repeater system. There are more complications with this kind of operation with SSB than with FM, admittedly, but none that are not handleable.

While translators such as those Oscar satellites use work very well, the auto-tuning nature of a phase locked system might be preferred.

Several means of doing this can be used. Basically, an SSB signal with a partially suppressed carrier (-6 or -10 dB) is transmitted and the receiver filters it out, limits it, and phase locks the BFO to it, so that automatic frequency control is maintained. It does not affect the other characteristics of SSB. Bandwidth is still under 3 kHz. Average power drain is still less than FM. Phase distortion is still less than FM. Additionally, a carrier-operated squelch and call-up system can be used very easily.

ADVANTAGES OF SIDEBAND

Excellent Range

Since SSB uses a narrower bandwidth, it has better weak signal efficiency. Its range is about one and one half to two times that of FM.

Narrow Bandwidth

Five kilohertz channels are not out of the question with SSB. Occupied bandwidth of less than 3 kHz yields reasonable fidelity.

Reduced Multipath Distortion

Sideband is narrow and does not depend on carrier phase, so it is far less affected by reflections and phase distortion. Even phase locked systems are not affected, as the BFO, not the transmitted carrier, is used for detection.

Simplicity

While FM transmitters are relatively simple, SSB transmitters are not that much more complicated. SSB receivers are certainly simpler than the FM receiver. Sideband modulation can be set by measuring output power and looking at an oscilloscope. FM deviation requires more complicated (and expensive) equipment.

WEAKNESSES OF SIDEBAND

Critical Tuning

The main criticism of sideband is its requirement of close tolerances. Tuning must be within 30 to 50 cycles for natural sounding reception. While in the days of tubes, crystal ovens, and 10 Amps of heaters in the box, this may have been a real problem; today's rigs with a normal multiplication factor of 12 generally hold a tolerance under 300 cycles. Since SSB is normally heterodyned up to frequency, drift can be kept to 1/12th of this, or under 30 cycles. And, of course, a clarifier system can be used over a limited range, such as plus or minus 300 cycles. Phase lock techniques may also be applied.

More Difficult Noise Suppression

While it's not difficult to recognize the greater difficulty of suppressing impulse noise, etc., in SSB, the problem is not as insoluble as one might suspect. Noise blankers, even of simple design, do very well in most cases. More complicated designs do even better. Frankly, under weak signal conditions sideband is much easier on the ears than FM's "chunk ... chunk ... ker-chunk" and high pitched rushing.

More Difficult Tone Access, etc.

SSB is not compatible with the high accuracy subaudible systems used by many systems at the present time. There would be little problem for audible burst systems, as the frequency tolerances are not as tight as those at subaudible, but subaudible could only be used in a phase locked system. Of course, in a phase locked system the generation of subaudible would be simpler than the present system of requiring only a crystal oscillator of the appropriate frequency near the transceiver i-f. In other words, with a 10.700 i-f a 10.700.100 crystal oscillator would generate the subaudible quite easily. Cost would be about the same, of course.

Range — Putting Numbers to the Theory

Since SSB requires a receiver bandwidth less than 3 kHz for fairly good fidelity (250-3250 Hz), while FM requires about 12 kHz, sideband shows a 6 dB advantage in sensitivity (based on dB = 10 log BW_1/BW_2).[4]

As only one sideband and no carrier is transmitted, there is a theoretical advantage of an additional 3 dB in the transmission of SSB. Sideband doesn't have to split its loyalties between two (or more) sidebands, as does FM.

Assuming this 9 dB advantage, one can easily see that a signal that is 9 dB out of the noise in a sideband system will not even be detectable in an equivalent FM system! While 9 dB S+N/N ratio is by no means a spectacular signal, it *is* readable, especially in an emergency situation.

Looking at it from a different viewpoint, if we assume that 1 uV is a reasonable signal level and that SSB has a 9 dB advantage in system gain, the following calculations give us some idea of sideband's range extending characteristic.[5]

$$e = \frac{3.2\, a\, h \sqrt{ERP}}{d^2\ \text{Lambda}}$$

e = 1 uV
a = 30 feet (base antenna)
h = 6 feet (mobile antenna)
ERP = 25 W x 2 (base power x ant. gain)
d = unknown
Lambda = 2 meters

Shifting the formula around yields:

$$d^2 = \frac{3.2 \times 30 \times 6 \times \sqrt{25 \times 2 \times 1^*}}{1\ \text{uV} \times 2\text{m}} = 2036$$

d = 45 miles

Adding the 9 dB effective gain of the SSB system, we have:

$$\text{Power gain} = \frac{9\ \text{dB}}{10}\ \text{antilog} = 7.9\ \textit{times}$$

$$d^2 = \frac{3.2 \times 30 \times 6 \times \sqrt{25 \times 2 \times 1 \times 7.9}}{1\ \text{uV} \times 2\text{m}} = 5724$$

d = 75 miles

As one can see, the advantage is about 1.7:1 (75/45) for SSB over FM.

continued

*25 W x 2(tx ant gain) x 1(rx ant gain)

Practical Experience

With the introduction of the Echo II by KLM a short while ago, many hours of experience with VHF sideband have been logged. Since the rig is solid state, it is a natural for mobile, and many have put the rig into mobile service.

I've been involved with this mode for some time, and have noted the superiority of sideband over FM for simplex work in the rolling hills along the California coast. Between my home in Santa Cruz and my job in Watsonville (some 25 miles away), I have had only fair results with most FM stations. With SSB I am able to get very good signals from even a 3 W PEP station over the same distance, and I work several San Jose area stations with good signals (about 40 miles, through 3000 foot mountains).[6]

San Francisco Bay area stations have little trouble working simplex from mobile to base from almost anywhere in the area (about 65 miles long by 30 miles wide) and frequent contacts outside the area are logged. In fact, higher powered stations (70-140 W) are consistently working out to 125-150 miles from their mobiles, with occasional contacts out to 320 miles.

Cost Effectiveness

The introduction of the ICOM IC-202 two meter SSB walkie-talkie demonstrates clearly that the cost factor of SSB need not be higher than that for FM. This unit lists for about $270 in the U.S. Considering that the 202 has bandswitching (4 bands), VXO (200 kHz), CW, S-meter/RFO meter, noise blanker, and several features not required for normal commercial service, its price is comparable to current FM rigs. It is also well designed in technical areas. Measurements at SBE on two separate units showed transmit distortion products to be -30 dB below each tone of a two tone test (-36 dB by ARRL methods). Receiver intermodulation was 70 dB (+10 kHz and +20 kHz). Receiver sensitivity was 0.125 uV @ 10 dB S+N/N ratio. The noise blanker is quite effective, and AGC holds the audio to less than 15 dB change from 0.3 uV to over 1,000 uV.

A Chance to Participate

This is where amateur radio can do something that is in keeping with the highest tradition of its service. We can experiment with something that the commercial boys have written off (much like they wrote off those "useless" frequencies above 2 MHz years ago). Some of us on the West Coast have taken a tip from the Oscars and kicked around the idea of a sideband translator in the middle of California. Considering the direct distances common to SSB, much of the state could be covered by such a machine. Anyone interested should contact me. Others should take up the task in other areas and with other ideas (such as phase lock techniques, tone squelch, etc.).

We've already seen the potential of the mode, but more data and more active stations are needed. It's lots of fun, too, by the way! See you on two sideband? ■

Son of the Overload Relay

- - if you can't buy 'em, build 'em!

In theory, an overload relay should be part of every amateur installation, especially those running high power. When placed in the negative high voltage lead, these protective devices can prevent many an expensive headache. These relays used to be listed in all the ham radio catalogs, but they are often difficult if not impossible to locate in the modern electronics emporium. However, it is relatively easy to utilize an inexpensive surplus item and to come up with a suitable overload relay. This should prove to be a worthwhile addition to any ham rig.

A surplus 24 V dc relay from the Command Set Unit is used in this circuit. This item is number 7735 and is found in the small tune-up unit, BC442, found in every complete aircraft installation. Hundreds of these units are gathering dust in ham shacks across the land, and in case you may not have a spare BC442 on hand, they are still available on the surplus market at prices as low as $5.00. For this price you will not only obtain the necessary relay, but also a very accurate and rugged rf meter with expanded scale. If your luck holds out, you might even find a surplus 50 uF vacuum condenser hooked into the back of the unit.

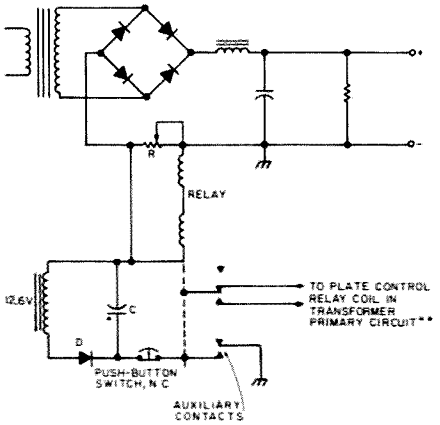

*Fig. 1. C — Electrolytic filter condenser, 100 uF (minimum value, preferably 250 uF), 25 V; D — Diode, ½ Ampere, 100 piv or more; Ry — Relay, part no. 7735 from Command Set Unit, BC442, resistance approx. 170 Ohms; R — Suitable for current drain, suggested starting point is 3 Watt, TV type 100 Ohm potentiometer; SW — Normally closed, push-button switch. **Note 1: Relay contacts may be used to control transformer primary directly if primary current is 5 Amperes or less. Note 2: If power transformer also furnishes filament supply, the main set of contacts may be used to open the high voltage, either in positive or negative lead, since the relay is insulated for high voltage on these contacts.*

Referring to Fig. 1, we note that when a pull-in current of some 90 mA is applied to the relay coils, the normally closed set of contacts at the end of the relay arm will now open. However, unless we employ some sort of "latching," the relay will continue to oscillate back and forth as long as the overload exists. To prevent this, the auxiliary set of contacts (normally open) are used to connect a small dc voltage to the relay coils, thus keeping the relay energized once it has been actuated by an overload.

This auxiliary voltage can be easily obtained from a small 12.6 V transformer, since only 100 mils are required at most, and even this small load is of an intermittent nature. The 12.6 V ac is rectified with a small silicon diode and filtered with a low voltage electrolytic condenser. This will give approximately 17.5 V dc, more than adequate for holding the relay in the "overload" position once it has been actuated. Or you might use a 6.3 V ac transformer with a voltage doubling circuit.

If and when the overload is removed, a quick push upon the release button will interrupt the holding current, thus restoring the relay to its normal position. Should the overload persist, the relay will be triggered again, thus protecting your valuable equipment. The purpose of the resistor R, wired in parallel with the relay coils, is to allow individual adjustment so that the relay will not kick out at normal operating currents.

The setting of the variable resistor is determined by the dc resistance of the relay coils, roughly 170 Ohms, and the amount of current that the operator desires to bypass around the relay coils. For example, assuming you want the relay circuit to kick out at 300 mA, it would be necessary to shunt a resistor of approximately 65 Ohms across the relay coils.

Some experimenters may object to the drop of 10 to 15 V when the relay is in its normal position. This is a very small loss when it is compared with an operating potential of some 2000 to 3000 V. However, for the ham running low power, the relay coils may be rewired in parallel in order to operate on half the dc voltage first mentioned for hold-in. In this case, this would be approximately 9 V dc. This can be obtained from a 6.3 V filament transformer, plus the necessary silicon diode and low voltage electrolytic filter capacitor.

In this lower voltage application, the current is roughly doubled, so it would be advisable to increase the

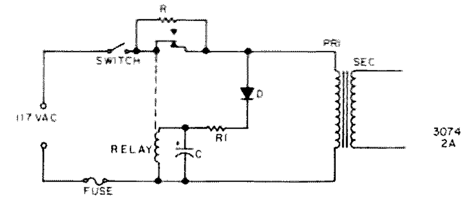

Fig. 2(a). Surge suppressor circuit, primary. For 1 kW (ICAS) power supply. Per Radio Handbook, *17th Edition, page 727. C — 800 uF, 50 V; R — 5 Ohms, 50 Watts; R1 — 600 Ohms, 10 Watts; Ry — 24 V dc, 280 Ohms (typical); D — ½ Amp, 400 piv.*

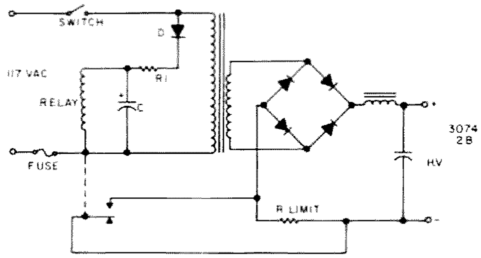

Fig. 2(b). Surge suppressor, secondary. D — ½ Amp, 400 piv; R1 — 500Ω 10 W, W.W.; C — 500 uF, 25 V; Ry — part No. 7735 from BC442; R limit — according to power, suggest 25Ω per 100 volts.

size of the filter condenser. Such a setup would be very suitable for a small linear amplifier using several TV "sweep" tubes in parallel. Some hams may find it inconvenient to ground the circuit at the two points shown on the schematic. This is overcome quite easily by mounting the relay on a small piece of bakelite. In this case, the two points in the circuit with ground connections must be "lifted" from ground and connected together.

Knowledgeable hams will spot a further function for this relay. It makes a fine shorting relay for surge suppressor use in power supplies. Most ham rigs, with condenser input, use this protective circuitry, but locate it in the primary lead to the HV transformer. This is done since suitable relays with good high voltage insulation are not usually available to the home constructor.

Commercial rigs, on the other hand, generally place the surge suppressor in the secondary of the plate supply. The current limiting resistor then becomes considerably higher in value than it would be when put in the primary circuit, roughly in proportion to the ratio of voltages. If a 120 V circuit were using a 20 Ohm resistor to limit current inrush, then a similar wattage resistor would be placed in the secondary circuit; but if the supply delivered 1200 V, the resistor ought to be roughly 200 Ohms. This would limit the inrush of current to a maximum of 6 Amps.

It is best to be on the safe side and to go to a slightly high value of resistance, rather than too low. As an example of commercial practice, the surge suppressor circuit in a 25 kW commercial television transmitter uses a 2500 Ohm, 200 W resistor, to limit current inrush to a 36 uF bank of filter condensers operating at 6500 V dc.

The values listed under Fig. 2(b) represent a compromise. Other R-C values may be used, but they will alter the time constant. ■

No-Wire Antenna Switch

- - a clever remote system

It seems we are living in a period of shortages and, in case you hadn't noticed, we hams seem to be facing another shortage, that of coaxial cable. I don't know exactly what has caused this shortage but I do know that coax is getting tougher to get. This article describes a remote switch that can result in a substantial savings in coax and may simplify multiple antenna systems.

Originally I came up with this idea to feed a tri-band quad. Now, the quad is a fine antenna and the fact that it can easily handle three bands makes it even better. However, there is a little problem in feeding three driven elements on one antenna. Neither three feedlines nor a matching system appealed to me, and neither did using three hundred feet of RG/8U. The result was a remote switch mounted on the boom of the quad with one feedline to the shack and separate lines from the boom to each element. This saved quite a bit of coax but added a control line for the remote switch. There had to be a better way.

After some experimentation, a remote switch was perfected that did not need a separate control line, used inexpensive relays for switching, was small enough to mount on the boom of the antenna, and did not cause a noticeable increase in swr. In order to eliminate the control line, the antenna coax was used to carry dc to the relays while also carrying rf to the antenna. This dual use of a feedline is a very common practice in TV antenna preamps where the preamp is mounted on the antenna. The feedline carries power to the preamp and signal back to the set.

To accomplish the necessary switching, two relays are required. With both relaxed, the 20 meter element is connected to the main feedline. With one relay energized, 15 meters is connected, and when the other relay energizes, 10 meters is connected. To make independent selection of the relays possible, steering diodes are used in series with each relay. Then by simply reversing the polarity of the control voltage, either relay may be energized.

Remote control is handled at the operating position by the control unit, which houses a simple power supply. Referring to Fig. 1, rf is fed into the control unit at J1, passes through C1, and comes out at J2. RFC1 is used to prevent rf from entering the power supply while allowing the dc voltage to be applied to the rf line. Capacitor C1 blocks the dc from getting back into the transceiver or linear. Switch S1 is a center-off slide switch and is used to provide either a positive or negative voltage to the rf line.

At the remote switch end of the system, the rf passes through C2, through the contacts of relays K1 and K2, and out to the appropriate antenna. If no control voltage is applied to the line, rf will be fed out to J4. If a positive voltage is applied at the control unit, relay K1 will energize and rf energy will be fed out to J6. If a negative voltage is applied, relay K2 will energize and the rf will be switched to J5.

In constructing this project, it is necessary to use high quality relays for K1 and K2. Since they will probably be mounted up on the tower or even on the boom of an antenna, they must be reliable. The relays used here were surplus types of the hermetically sealed variety and had 24 volt coils. Keep in mind that, if you are using long runs of coax, there will be some loss of voltage at the relays due to the dc resis-

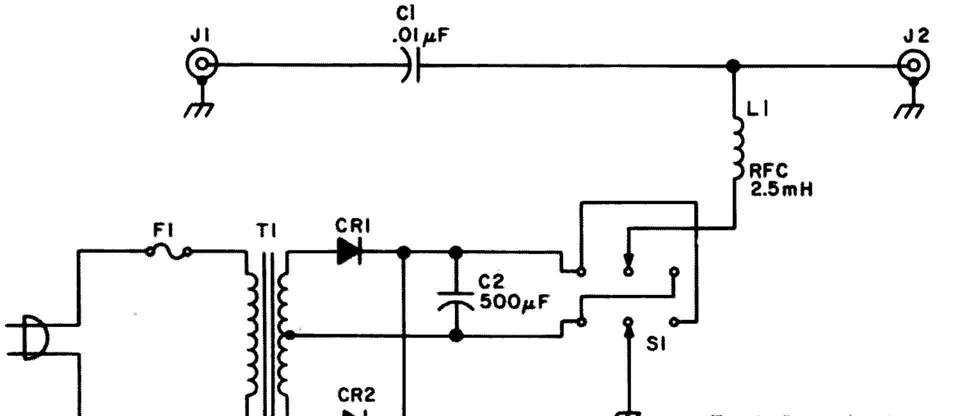

Fig. 1. Control unit.

tance of the cable and connectors. For this reason I do not recommend using relays with less than 12 volt coils. For example, the 24 volt units I used draw very little current and thus cause very little voltage drop to occur in the line. Also, the capacitors used at C1 and C2 should be capable of handling the rf power you plan to use. At the 200 Watt PEP level, I have found high quality disc ceramics satisfactory, but at higher power levels I recommend using transmitting type capacitors.

The power supply components are not specified because they will depend upon the relays used. Typically, a filament transformer and 1 A diodes should be satisfactory. Use enough capacitance in the power supply to keep the relays from chattering.

The remote end of the system should be built into a watertight container having appropriate mounting hardware to attach it to your tower or wherever you plan to locate the unit. Use coaxial cable to connect between the jacks and the relays, and anywhere the rf path is more than 1½ inches. This should result in a system with almost no reactance to cause high swr. Although I could not measure insertion loss on my unit, it appears to be very low. Below 30 MHz, I cannot tell any difference on my swr indicator when using the switch or connecting directly to my dummy load. At 2 meters it results in about 1.5:1 indicated swr. Since I only use it on HF, the swr is no problem.

This system of remote control has many possibilities other than those mentioned here. For example, if you only need it for two antennas, use only one relay. Perhaps with a little work this system could be used to switch the pattern on a set of phased verticals or wire antennas. All you have to remember in expanding upon this system is that the capacitors block dc and look like a short to rf, while the rf chokes pass dc and block rf. I have used this method in conjunction with a standard rf switch to work up a five-band antenna switch using three feedlines. Separate lines were used for 80 and 40 meters since these antennas were not located near each other, while 20, 15 and 10 meters used a single line. The saving in coax has been more than enough to offset the cost of building the switch, and not having the extra coax lines running into the shack has helped to clean up my operating area. I think you too will find this a useful and money-saving addition to your shack. ■

The Beeper

-- NASA-type beeping

For some time now, we have considered using the "begin/end" beep which NASA traditionally uses for all voice space communications. Its potential use in amateur radio, whether on the low bands, the two meter repeater band, or, for that matter, any phone band, seemed obvious. Perhaps the main concern with high noise QSOs, be it QRM, QRN, or simple wind noise when mobile, is trying to identify when the mike on the other end has been keyed or dropped. A device similar to this one has been incorporated into some repeaters, but usually only as an "out" indicator.

The specifications we desired for such a device were clear. It would:

1. Automatically initiate a beep when the mike is keyed either on or off.
2. Produce a different frequency beep for each status. We preferred to use a high tone going in and a low tone coming out.
3. Produce the tone for only about one half of a second and hold the transmitter in while it was being produced in the "out" state.
4. Be totally solid state with no use of relays or electromechanical devices.
5. Be inexpensive and easy to build, with readily available parts.

The final version was designed specifically for the Kenwood TS-520 transceiver, but a relay option was added to allow use with any transceiver or transmitter. The unit operates conveniently from a 6 V dc power cord used for calculators, tape recorders, etc. In this sense, no power supply was needed. The power cord we used was bought from a clearance supply of calculator power cords, for which there was no longer a calculator made. They are available new for about $4.99, but most surplus houses have them for half that. We found that a few power cords we tried would not work properly, causing the unit to switch back and forth between tones. This was traced to a poorly regulated supply, which caused the unit to

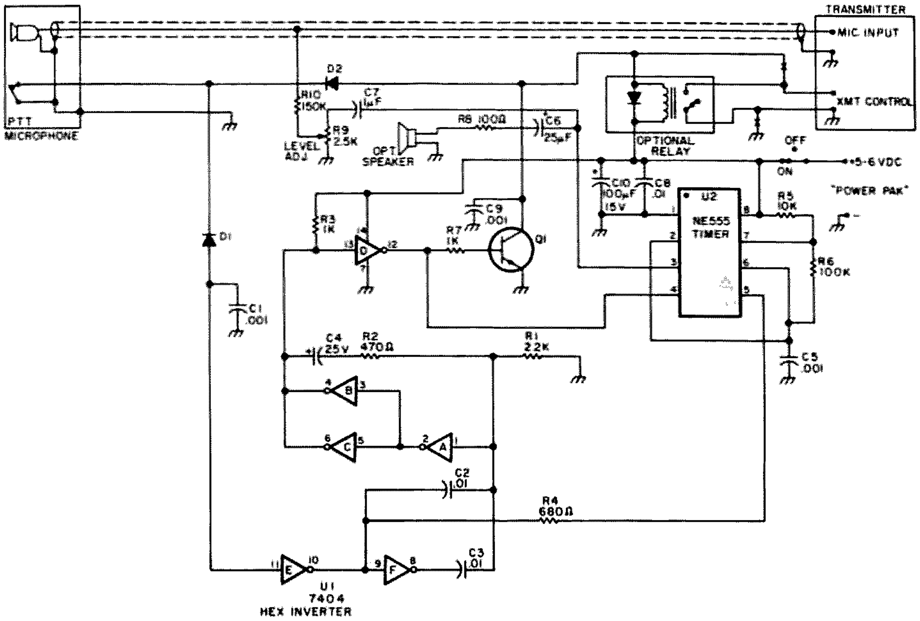

Fig. 1.

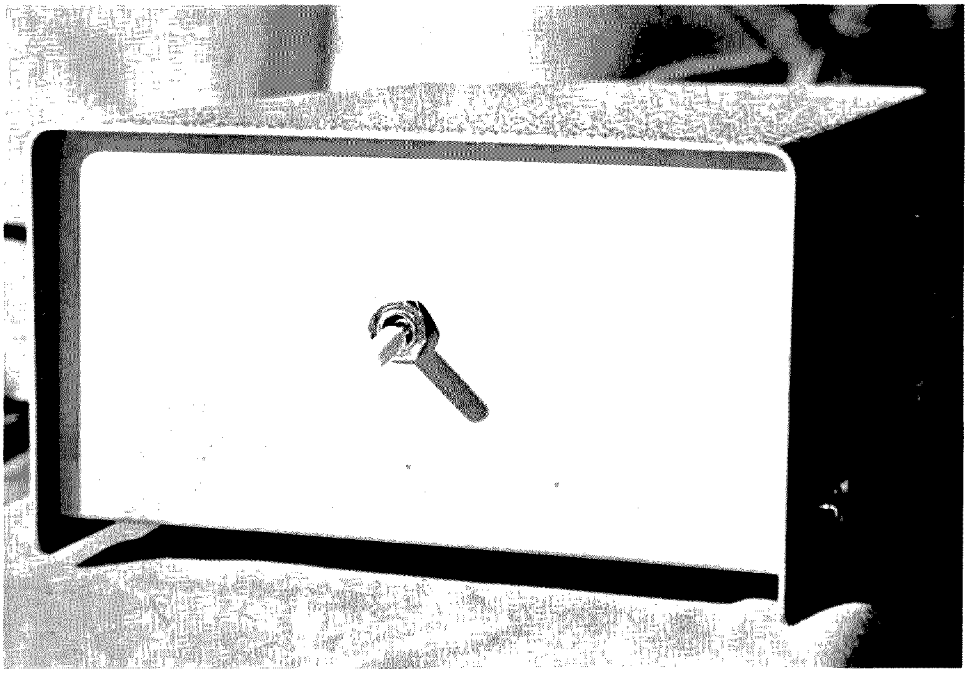
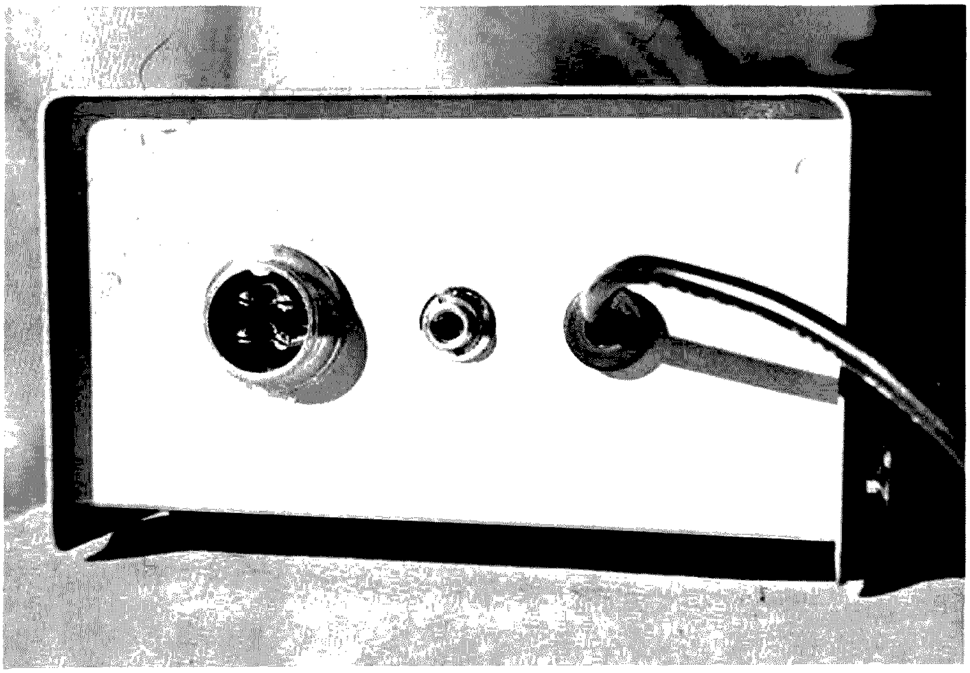
switch on and off. The unit, of course, works fine on batteries, so this method can be considered for portable operation. Also, our final version incorporated a speaker so that the operator could be assured that the unit was functioning properly. This audio feedback adds less than $1.00 to the cost, and can be disregarded if not desired. (However, this option is an attention-getter.) Finally, the beeper does not interfere with normal transceiver operation when turned off. No disconnection need be made at any time.

Basically, the "NASA Type Beeper" uses a 555 IC as a tone generator because of its ability to directly drive a speaker, be turned on and off by a TTL control signal, and vary the frequency of the tone by using the "modulator input" pin. A 7404 hex inverter provides buffering functions and a monostable multivibrator with a one half second time duration. Inverter sections A, B, and C form the monostable multivibrator. When depressed, the PTT microphone switch supplies a ground through isolation diode D1 to inverter section E. Its output goes high, sending a positive pulse through capacitor C2 and causing inverter F's output to go low. This sends a negative pulse through capacitor C3. Capacitors C2 and C3 are connected together and drive inverter A, the first stage of the monostable timer. It would appear that the opposing pulses through C2 and C3 would cancel, but the output stage of each inverter section is far better able to produce negative pulses than positive ones. A good scope shows a healthy negative pulse at the input to inverter A whenever the mike button is closed or opened. Thus the one half second time period is initiated at the beginning and end of each transmission. During this time period, the output of inverter D goes high, enabling the 555 timer and turning on transistor Q1, which is used to hold the transmitter on during the "out" status. The transmitter thereby "waits" for the "out" beep, even though the PTT switch has been turned off. The "modulation" pin of the 555 is connected through resistor R4 to the output of inverter E, so that, depending on whether the PTT switch is open or closed, a different frequency tone is produced. The tone is fed into the high impedance mike line through trimmer R9 and resistor R10. R10 should be a 10k for a low impedance microphone. The trimmer allows the tones' level to be controlled.

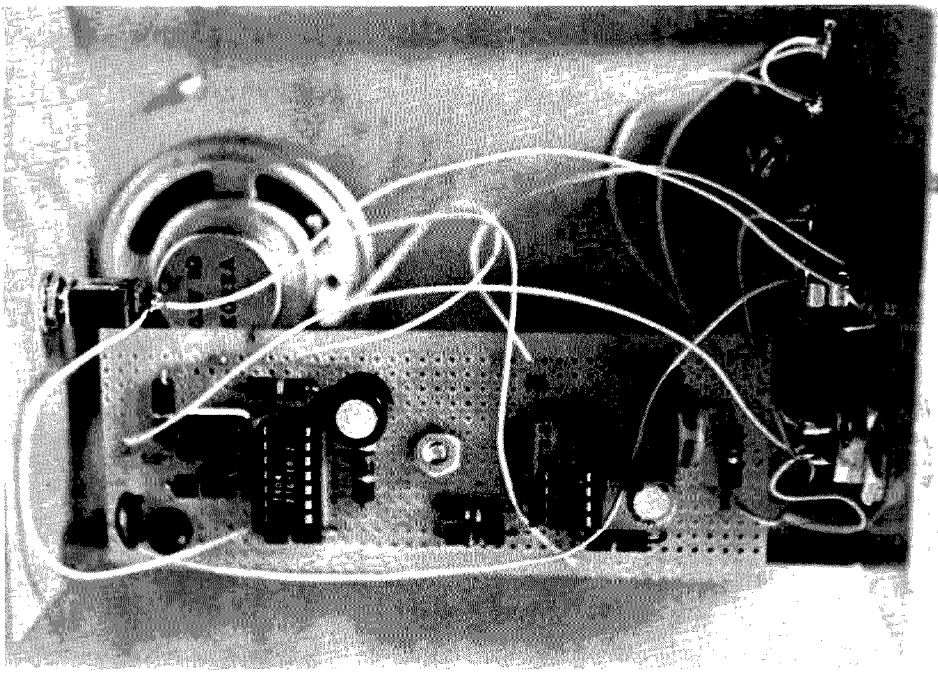
If the transmitter you construct this unit for requires the completion of a voltage higher than 30 volts, a negative voltage, or a system other than the grounding of 12 V dc as in the Kenwood TS-520, then the relay option should be used. The relay should operate on 6 volts at low current to reduce power consumption. Radio Shack offers an SPST 6 volt low current relay that is ideal (see Parts List).

Construction hints: The unit fits most conveniently in a 6" by 4" by 2" minibox, which allows extra room should you want to incorporate the relay. Point-to-point wiring was used on our





Photos by John Farquhar



unit, as it seemed less bother than making a printed circuit board. The ICs were mounted in sockets to allow quicker servicing or troubleshooting, but this is an "extra" and the ICs could be soldered into the circuit. One single stand-off was positioned in the center of the board, using a single screw and a few nuts. All interfacing connections were placed at the rear for cosmetic reasons and only the power switch was placed on the front panel. A few holes were drilled in the bottom of the case and a small 8 Ohm speaker was epoxied to the case. One note of caution: Shielded cable should be used between the transceiver and the beeper to prevent rf pickup.

After continual use of the unit for a month or so, we found the beeper to be a novel and useful addition to the station. We have experienced no confusion in QRM situations as to when we have switched back to the other station. In fact, operating the transceiver without the beeper on leaves quite a void now and something just seems missing. Happy beeping! ■

Ham Phone Answering Service

-- leave messages

The advantage of crystal-controlled transceiver systems for dependable short range communications is known to many amateur radio operators. This is especially true on two meter FM where many amateurs use

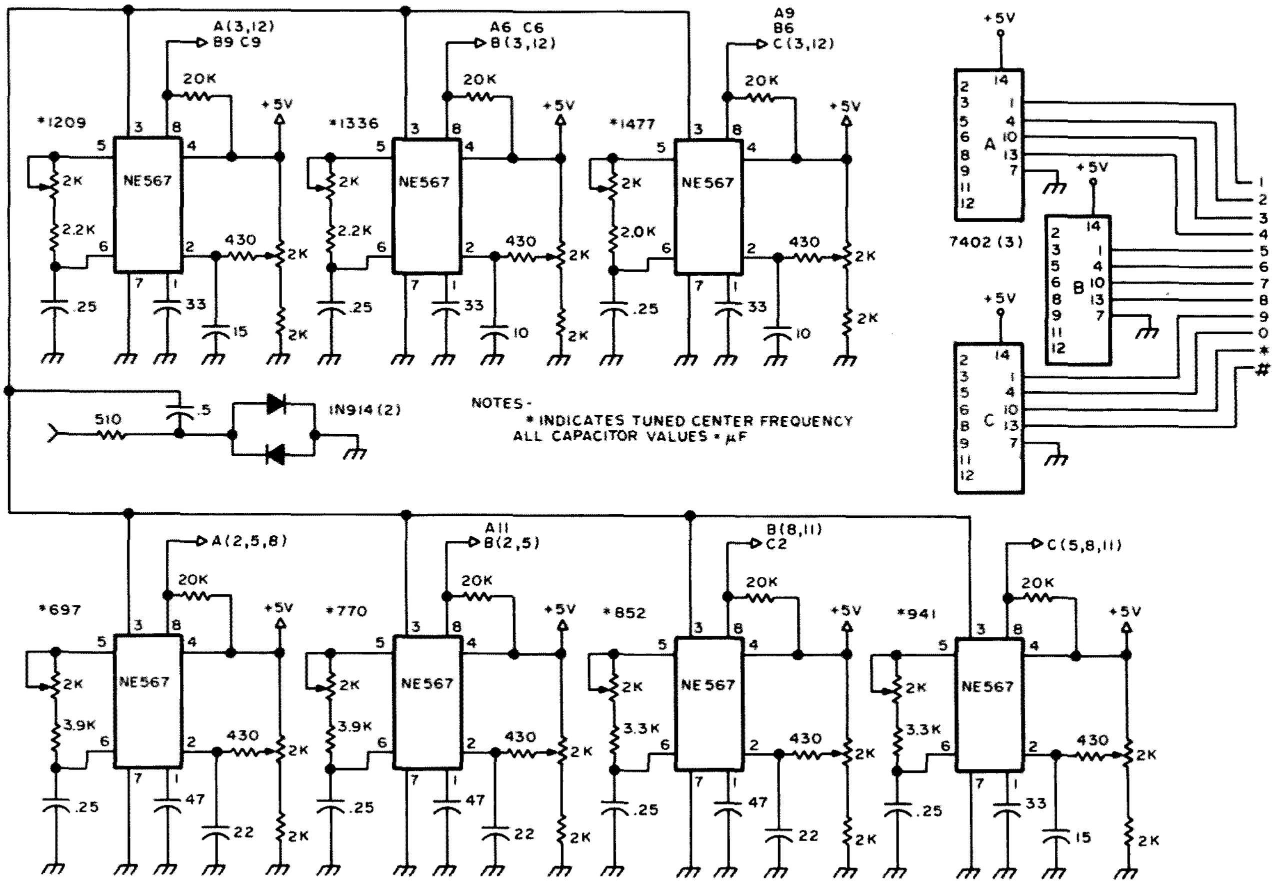

Fig. 1. Tone decoder. It is good practice to bypass all Vcc pins on all chips with a .1 uF capacitor. The 5 volt power supply should be regulated to ±5 mV ripple.

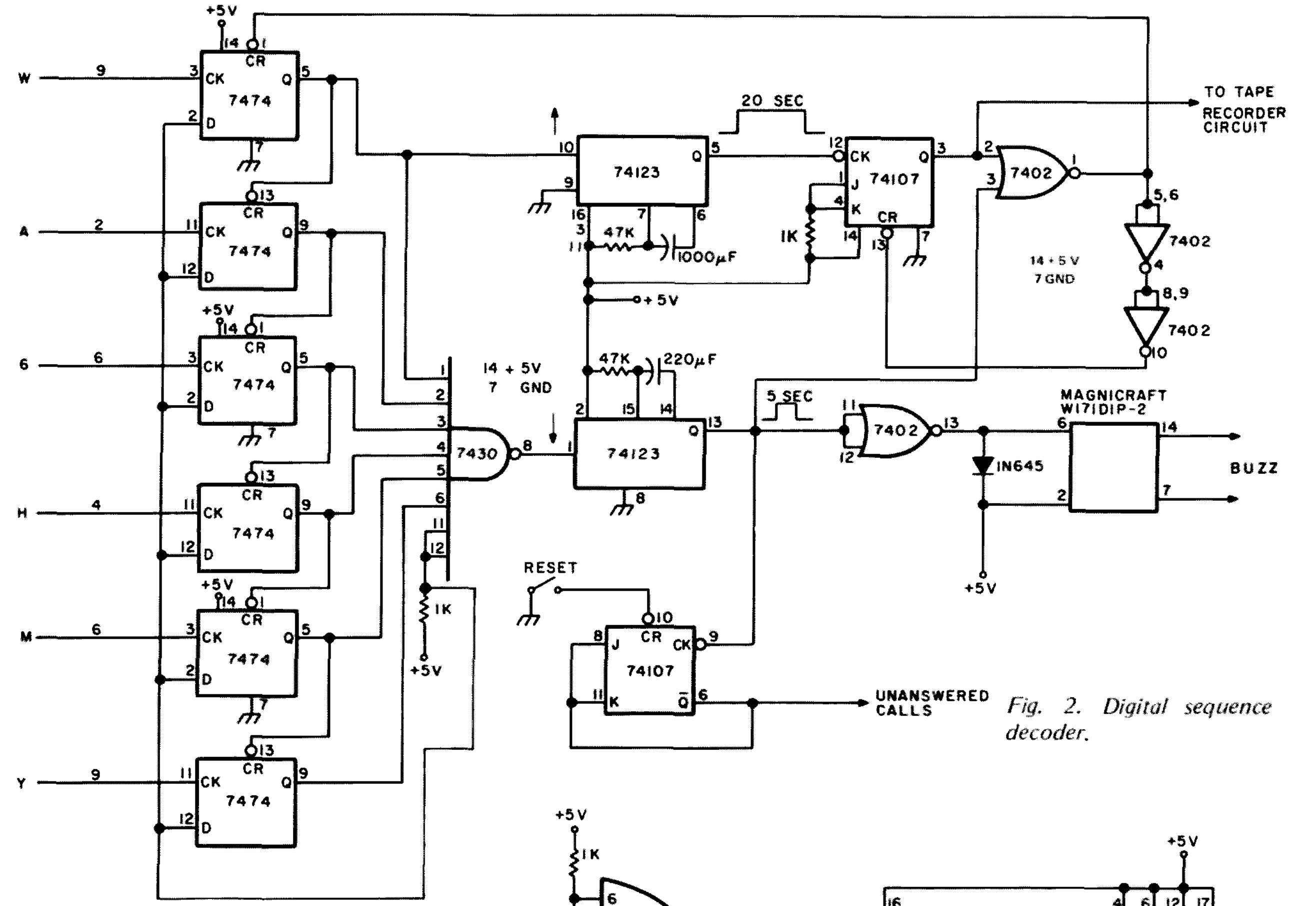

Fig. 2. Digital sequence decoder.

this capability to communicate from car to house. Many of us OMs have pursuaded our XYLs to get their amateur radio licenses so we can talk to them from car to house. But with all the brilliant technology of our beautifully human-engineered turnkey transceivers, there has been one big problem. The XYL won't turn on the receiver because of all "that horrible clicking and chatter from other stations."

The amateur radio telephone answering service and a touchtone pad solve this problem. It works like this: You're in the car and press up the XYL's call letters, a buzzer goes off in the house and she then turns on the speaker of the trans-

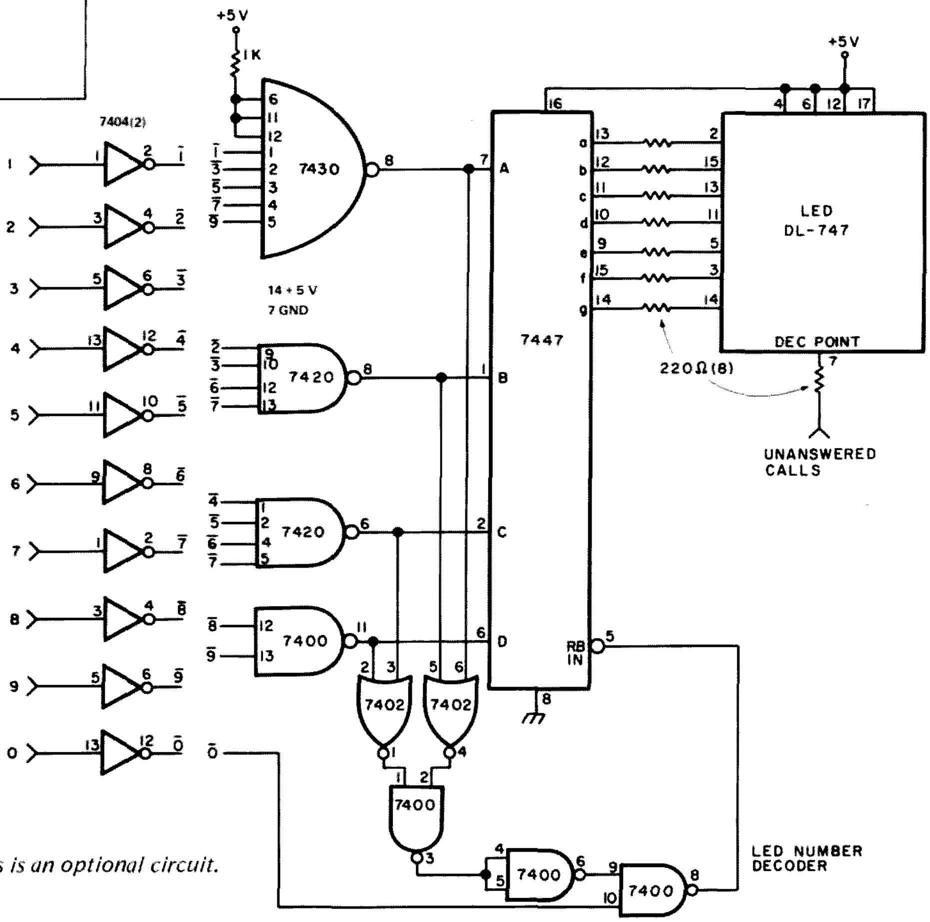

Fig. 3. LED number decoder. This is an optional circuit.

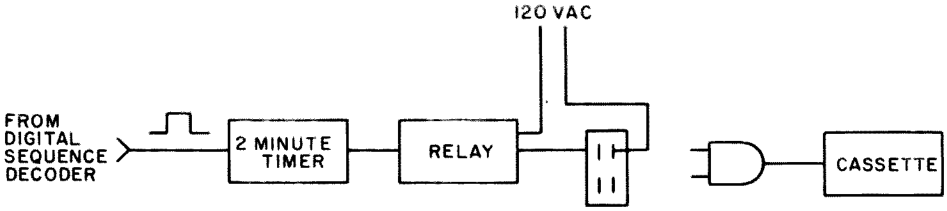

Fig. 4. Tape recorder circuit. Note: Depress record button on the cassette player.

ceiver and the QSO begins. If she missed the call she will see a light indicating a missed call and she can then play back a cassette recording of what was said on the channel.

Functional Description

Fig. 1 shows the tones coming off the transceiver speaker where they are converted to 12 digital logic outputs. For example, if the #2 touchtone pad button is depressed, the #2 line out of the tone decoder outputs 2.5 volts (a TTL logic one). All of the remaining 11 lines are .4 volts (a TTL logic zero). As the tones are decoded in a precise order, in this case WA6HMY, which is 926469, the digital sequence decoder outputs a relay closure which activates the buzzer for five seconds. When the buzzer stops, the missed call light comes on, which can be turned off with the reset switch in case other calls come in. If the reset switch is not pushed, then 15 seconds after the buzzer stops the tape recorder records what is being said on the channel for two minutes.

As the tones come in, the LED indicator will display what numbers are being sent. This is handy for checking out touchtone pads.

Circuit Description

The tone decoder circuit is taken from the Signetics application notes on phase locked loops. The values of the resistors and capacitors were calculated with my junk box in mind. The only critical component is the .25 uF capacitor used. It should be made with mica or polystyrene or of equally temperature-stable material. This circuit should be tuned up using an audio generator and a frequency counter. Put the counter on pin 5 and tune the left pot so that pin 8 pulls down to .4 volts when the counter reads the correct frequency as you adjust the audio generator. Tune the right pot to get a 4% bandwidth. There is interaction between pots, so it requires some tuning back and forth. Each of the seven phase locked loop integrated circuits are tuned to the proper frequency in this manner.

The digital sequence decoder, LED number decoder and the tape recorder circuit require no special care and feeding. One can program the sequence decoder for any callsign or name or number sequence up to six digits.

I and several other hams in this area have built and used this amateur telephone answering system. It has made more efficient use of the populated channels and allowed annoyance-free 24 hour monitoring. ■

Recently there has been a lot of loose talk about making a greater effort to recruit a new wave of radio amateurs from the CB ranks. Fraternal welcome is a nice idea, and if there are other motives, self-interest needs no defense. But candor is important too, and has anyone mentioned the hazards of hamming? Let's be decent about this; we are dealing with innocents.

Ken Cole W7IDF
P.O. Box 3

Dear Good Buddy

- - the perils of radio

When you think of all the eleven meter groundplanes sprouted among the thickets of TV Yagis and visualize a CB migration to the ham bands, TVI comes first to mind, but in fact it is a routinely soluble problem already competently dealt with in countless articles. There are subtler perils, seldom referred to, lying in wait for the artless neophyte.

One type of trouble is invited simply by the switching of roles, the assumption of a new identity in the public mind. It is commonly thought that the CB operator is a social activist seeking conviviality and opportunities to lend a stranger a helping hand, but the radio amateur is seen as less comfortably explicable – a kind of enigmatic technician who takes mysterious pleasure in messing with electrons and communicates only with others of his arcane persuasion. The operative word here is technician, and as used it means that, unlike Citizens Banders, he understands, designs, constructs and fixes electrical things. Many people really do think this, and sometimes it seems that they all live next door.

To illustrate: Your neighbor knows you have a CB set, but when the automatic ice cube gadget in his refrigerator fails, it doesn't occur to him that because you talk to people on a radio you should have the privilege of dealing with his ice cube crisis. However, if he knows you are a ham, the situation is very different. Inexplicably you are transformed into Mr. Fixit, Savant of Electricity and, needless to say, Public Servant. With the speed of light the ice cube machine magically lands in your lap. If you fix it, your fate is sealed. The word is passed from cell to cell, the failed and feeble toys gathered up, and one by one your neighbors knock on your door, burdened with electrical detritus. Some are humble and others are astonishingly peremptory, but there is a depressing uniformity about the junk culture treasures they entrust to your care – they are out of warranty, grimy with dust, sticky with the residual miasma of short-order cookery, long-parted from their proud instruction manuals and the plastic cases are cracked. Most bear unfamiliar brand names, anonymous bargains from discount stores, and have the sad appearance that means abused and unwanted.

Almost every other repair job will be a certain type of TV set, heavy and inclined to tip over slyly with the nearly imperceptible acceleration of a sleepy drunk. These are called "portables" no matter how much they weigh, presumably because they aren't in a castered cabinet fitted with a turntable, a "control center" and two boomy woofers. All are series string and after removing the cracked plastic back, shard by shard, you will find that the last tube you check will have the open filament. Reassembly will require your wife's help and the temporary application to the plastic fragments of bits of Scotch tape, Duco cement and profanity. If putting things right isn't all that simple, you can try to explain to the owner that you need and don't have the proper scope, sweep generator and other shop gear. The look you get in response will tell you instantly that he is certain you are lying, indifferent to his misfortune and too lazy to help. This is the time to tell him what you should have said in the first place: that there are many good citizens in the business community trying to make a living for their families by fixing just such beat-up old idiot boxes. Say this politely and firmly. You'll feel good, and in the silence that follows you may hear your wife snicker in the kitchen.

Children are a smaller problem, even when they are six foot teenagers, but sooner or later every kid on the block will show up with a lifeless ten dollar transistor squawk box. They all have several and when one quits it is simply stuffed in a drawer and forgotten until word about Mr. Fixit gets around. The battery holder is thoroughly corroded, the dial cord broken and an invisible crack in the circuit board testifies to the last and fatal tumble from a skidding bicycle. Fix it and the kid's dad will appear at your door with a grateful smile and an armload of sick stereo. "How come not having the speakers connected would blow the output transistors? It didn't make a sound." In return for his grateful smile, you have handed him a mystery and he regards you with suspicion. Do you explain the theory and practical application of transistors in two minutes, or do you say, "Please, sir, you must just trust me, for I am Mr. Fixit?" He has the advantage, for no good deed goes unpunished, as the philosophers point out, and by doing a favor for his son you obligated yourself – another lesson learned? But you can't turn a kid down, can you? Well, you could refuse your technical help except to runaways and orphans. The message is on the medicine

label: "Keep out of reach of children."

But not to worry. Think about the bonus fringe benefits of having a ham ticket: Finally you have met all those fine neighbors you managed to avoid for years; your troubleshooting expertise has been honed and polished; you've learned so much about human nature that the rising tide of violent crime no longer perplexes you — now you think of a screwdriver as a weapon instead of a tool. No more fretting that the country is flooded with crummy unfused ac-dc junk, that behind every loose plastic knob is a metal shaft connected to the nation's power grid. You no longer wonder how much assurance is implied, and how much genuine concern expressed, when a factory affixes that "U.L." stamp or label. Newly toughened by exposure, you understand that it's a jungle out there, and one for which you were ill-prepared by the cheery ambience of CB, that Disneyland of the air waves. In return for wisdom and privilege you have forfeited your innocence, but what good was it anyway?

Once you have the free servicework panhandlers sorted out, it's a downhill feeling, and finally there is time to work some of that DX that tempted you away from the comfy slot on eleven meters where nobody bothered you. Then one evening as your wife answers the phone, there's a knock on the door and it's a whole new game. "Harry's the name, live down the street. The boy said you was a radio ham and go all over the world, right? Thought I'd say howdy to my cousin's daughter-in-law in the Peace Corps in South America. Think it's New Guinea." Take the phone, listen to a thought-gathering silence, a few hiccups and a fuzzy baritone: "Say, friend, you talk to foreigners on your little radio, huh? You admit that? Humph. Well, how about those people in Cuba and Russia? Yeah? Gummint let you do that? How ya know they're not spies? So what do ya talk to them for?" Smile and hang up.

Forget the nuts in the bleachers; what about home plate? The CB rig took up a cubic foot and cost two nights on the town, but ham gear is something else. The amateur license is in a sense a collector's item — an occult centripetal force is focused by your call letters and you will find yourself accumulating endlessly, if virtuously, in pursuit of diversity and improved performance. It's also a license to experiment — so test gear is attached, stacked and lined up neatly; surplus circuit boards and components overflow desk drawers and cartons. Discreet storage under beds and behind davenports is soon exhausted. I hate to mention money, but it is a fact that a beam can bite a budget cruelly, and a transceiver can swallow a family vacation whole. It was simpler for the old-timers, but today state of the art acceleration is phenomenal and, to the devout ham, intoxicating. Thus, "But you've only had this one a year, dear, and it looks just like new. And you were so pleased with it." The traditional reply ("Shut up and get dinner on the table") will not do. The CB rig is still in the kitchen, with sympathy on every channel. Times have changed.

Finally, it is only fair to mention that there are further risks attached to switching to hamming which, curiously enough, are concerned with the probability of making more friends. In exchange for giving up the doubtful option of anonymity ("Hey, Polish Princess, this is the Purple Cow."), hamming lets you know exactly who is on the other end of the horn. Calls, names, addresses and license class are in the callbook, so every QSO is that much more a personal and informative contact. And the diversification within the hobby (traffic nets, rag chewing, public service activities and DX riots) encourages closer contact based on shared interests. It is only fair to warn you that you may find that some of your new friends, helplessly adrift in a love affair with the electron, are inclined to take a rather light-hearted view of the more burdensome realities of life. Not to put too fine a point on it, aberration and eccentricity are not unknown in the ham community when imagination and ingenuity get out of hand.

An illustration: Not so long ago, when 21 MHz i-fs were standard in television sets, W7ATK (who shall remain nameless here), lived high in a TV-infested apartment building and an identifiable antenna would have violated a maxim of the TVI game — never blow your cover. The situation recalled an earlier and unpleasant experience with an adamantly unforgiving landlord informed by an aggrieved tenant that a trap vertical was not a "lightning rod." But the technical challenge was irresistible to a veteran of the FCC, and soon ten feet of base-loaded aluminum tubing was mounted on a bracket outside the bathroom window. Forty meters, with leakage on fifteen a calculated risk, and coil taps for moving the narrow bandwidth left and right. Atop it a plastic imitation anemometer spun merrily in the lightest breeze. Rational enough so far, but then instead of a simple ground to the plumbing, thirty-three feet of insulated wire (he refused to reveal what was on the end) was flushed down the toilet. On a table under the window the rig was disguised with a beach towel and assorted shaving gear. Bemused and too fond of inventing descriptive names for his ground system to listen to skeptical friends, ATK finally tired of wind-and-weather questions from curious neighbors and moved out of the city to a job with a broadcasting company. Long years of bossing me there encouraged early retirement, and presently he is writing a book, "It Only Hurts When It's Painful," about falling out of powered golf carts.

One more example, more illustrative of imagination then ingenuity: KL7AZH, now WA7LBX and once upon a time W7FQL, was inclined to view hamming as an avenue to unique accomplishments and "firsts" were his delight. To spare him any embarrassment from this account of one of his less successful efforts, his name won't be mentioned. He was living in a Bering Sea coastal village some years ago when suddenly he was severely afflicted with an urge to pull off an aeronautical mobile first, and since there was no way for wiser heads to prevail against a plan kept secret, he was soon airborne in an old Stinson with a pilot who had agreed to fly him from Wales over the Soviet island of Big Diomede. Visions of sugar plums danced in his head, spelling out "KL7AZH/AM/UAØ" or something like that. Now, looking back, he attributes his foolishness to his youth (he was only fifty), an unusually long winter and arctic fever. As it happened, circumstances intervened, infuriating him but preserving his spotless record with the FCC. The plane's Lear T-30 had been twiddled to eighty meters and tested with a dummy load on the ground, but over the ice floes and near the International Dateline it refused to function. Then the Lycoming radial threw enough oil to obscure the windshield, turbulence rocked the plane without mercy, and the fumes from the oil combined with fragrance from an earlier load of reindeer meat to produce pure nausea. Landing on return to Wales with vision restricted to the side windows was no problem, but someone

forgot to reel in the trailing antenna with its customary beer can fluttering at the end of the wire, and this took down a salmon-drying rack before parting. As the DXpedition stepped shakily to the ground, I asked him what he had been up to. "Get out of my way before I throw up on your mukluks," he growled, and then confessed. On his desk today is a battered beer can, and he likes people to ask him what it's doing there and why a burnt-out fuse is taped to it. Dreams die hard.

Currently WA7LBX is driving himself relentlessly to bring off another first: a QSL from every licensed blonde YL in Spain. A magnificent concept. But there is reason to believe the project isn't going too well. His wife, Martha, is only grudgingly supportive and complains that his normal cheeriness has so deteriorated under stress that waking him every morning is sufficiently risky that she pokes him with a long stick, standing well clear, and at the first sign of returning consciousness expediently trots off to visit a sister nearby. Hours pass before he is safely approachable. Alas, scaling the heights is a lonely business.

But most hams are just ordinary folks, good buddy, and it would be less than honest to leave you with the impression that the two gentlemen mentioned are representative. On the other hand, it's interesting that they're not regarded as all that odd. Some do say that spending years in the comparatively more potent rf radiation field of amateur radio does make a difference, and that the five Watt CB limitation was a lucky break for you people.

Well, so much for telling it like it is, more or less. Now gather up your courage and get that ticket. You'll never regret it, and welcome to the club. ■

LETTERS

from page 9

DOC to arrive at a final policy to be presented at the ITU Conference to be held in Geneva in 1970. From the outcome of the September 29th meeting, we have learned that the lower part of our UHF band, 420-430 MHz, might still be used by Canadian amateurs on a sharing basis with other services like beacons and radio direction finding, etc. The top part, from 440-450 MHz, will be taken away from us, to be used by satellite services. This leaves us with 10 MHz (430-440) which we can call our own. Keep in mind that these changes can come about at any time. There are 5 UHF repeaters in operation in the Toronto-Hamilton area at the present, and 37 UHF links at confidential frequencies to control various 2m repeaters. All of these are in the lower and higher parts of this band, i.e., 420-430 and 440-450 MHz. Also, amateur fast scan television is quite active in this area on 439.25 MHz (international simplex freq), and with 4 MHz bandwidth. The first amateur television repeater VE3TVR in Canada is being built here as well, and already cleared by DOC one year ago. More TV repeaters are being planned for Toronto and other areas in the country. There are 5 TV repeaters in full operation in the US; the Washington repeater has been going for more than 2 years, and many more are being planned. An amateur TV repeater takes up 12 MHz of the UHF spectrum. In western Europe, TV activity is very high. In Germany, a fast scan association was founded in 1969, in the same year England founded its association; their total membership at the present is well over 4000 hams. Fast scan in Canada is rapidly increasing. Readily available surplus UHF gear and cheap surplus CCTV cameras, and the simplicity and economy of readily available solid state devices and kits, make this all possible.

To my way of thinking, we are just beginning to make use of a "giant sleeper," the 70 cm band. Too bad that we might lose it, before we have a chance to use it. I suggest we all rally together and try to save this band, because once it's gone, we will never get it back. Discuss it on the air, at your next club meeting, ask your club executive to write letters to DOC stating our position. Support your amateur organizations and persuade them to fight this, or go all the way and write letters yourself.

"United we stand, divided we fall."

John Vanderryd VE3CYC
Hamilton, Ontario, Canada

PARASITE uP?

I am writing this letter in earnest support of Mr. Donald Peasley's letter to the computer section "I/O" editorial. I originally subscribed to *73 Magazine* because I was just a neophyte to ham radio and after the mail hype that *73* sent me — "more ads, more ham-related articles" — I took the bait. The mag has gone downhill ever since. It seems that the mag has developed a predilection-turned-penchant for microprocessors and computers and the like. I can see no need for one in my shack, as my Yaesu functions superlatively as ham radio and does the job for working the world (23 countries so far). This proliferation of computer-related articles has soured my one-time favor for the magazine. How about some more articles about gadgetry for the more abundant HF gear — Heath, Yaesu, Drake, etc? If I am not mistaken, these radios all perform well without a parasite microprocessor on their backs. The references to such strange and arcane terms like byte, ROM, RAM, software, interface leave me in the dust, and frankly I have no desire to understand them. The old saying goes, "If you want something done right, then do it yourself." It is particularly apropos here, as I would like to volunteer my services as a journalist and write some articles for the more conventional hams. Shortcuts for learning the code, building up your speed, observations on the ham bands, stories, and really relevant rhetoric on the affectation that we all labor, the attraction and excitement of the distant station.

Peter G. Kendall WN3ZRG
Newtown PA

Talk is cheap, Peter — let's see some of the articles you're promising. — Wayne.

POT SHOTS

Stop the presses! A few weeks ago I wrote you a letter concerning Trigger Electronics in Illinois. In the letter I stated that I had turned to Group W Broadcasting for help through their Call for Action program and that they had agreed to assist me in getting my money back.

Well . . . last week I received a phone call from the Chicago affiliate and we talked at great length. It seems that Trigger has quite a reputation out there. They had a "considerable" case file against them. Fortunately, my order was for only a few crystals and a filter (about $35.00). A few of our brother "hams" had ordered (but never received) entire station setups ($600.00-700.00).

The only lesson here is that anyone (especially the newcomer as I was) should be most careful when making a mail order purchase, even if it *is* very difficult to locate suppliers in some parts of the country (as is the case here near Cape Cod). Although it is most frustrating to wait for gear when you are all ready to go, 'tis far better to wait and search than to pay and never receive.

It may interest you to know how I first learned about Trigger's existence (but, unfortunately, not about their reputation). When I was first licensed last year, one of my first acquisitions was the ARRL's *Radio Handbook*. In there, there is a list of suppliers. I wrote to Trigger for a catalog, assuming that anyone who is listed in the League's handbook must have their endorsement. It was not until I had trouble with Mr. Treger that I wrote and told *QST* of my problem. A return letter stated that they had not let Trigger advertise for a few years, because of his "operation." It's a case of the left hand not knowing what the right hand is doing, I guess. The handbook, by the way is a '76 edition, the latest! Must have been too costly to have the page with the suppliers list reset for the '76 printing. Otherwise, they would have stricken Trigger's name.

I wish that I had subscribed to *73 Magazine* a few months earlier than I did. I would have known about Trigger then. Oh, well, Wayne, can't cry over that. Just renew my subscription for another three years and bill me directly. Better protect myself for future purchases.

No one told me that there is more to learn than the code and some theory.

When I upgraded to a General in June, I wanted to upgrade my station as well. I turned to *73* (again) and found Tufts Radio in Medford. Let me tell you, I found them friendly, prompt and fair. A few months later I ordered (by mail) a meter from them and got it within the same week (my check didn't even have time to clear before they shipped). They'll get all my business in the future!

Hope that this letter will save another newcomer from the hassle and frustration that I went through. Although we won't have Trigger around any longer, I suppose that there may be one or two more companies that operate with similar abandon. You keep up the good work that you are doing in your magazine. As for me, well, Wayne, if I find out about another one, I'm gonna take a few pot shots at them myself. I wrote about two dozen letters, all told, with this Trigger deal. I'll write a few dozen

SWR Myth Exploded Again

- - how does swr really affect signal strength?

Wallace H. Provost Jr. WA1JFU
15 Park Drive
Bedford NH 03102

Back a few years ago, when I lived in Vermont, I was discussing standing waves with a well-known amateur in Altamont, New York.

"Well, Wally," he said, "I had a standing Wave in my shack but I found she looked a lot nicer sitting down when she crossed her legs—love those mini-skirts."

Obviously that topic of standing waves is fine over a glass of beer in the local pub, but it is not the subject of this article.

I assume that the reader has already read the various handbooks and back issues of this magazine, and I will not bore you with dreary theory on transmission line design but rather get right into the meat of the problem.

Fig. 1 shows a simple station arrangement. The transmitter output matching network matches the impedance of the final tubes to the impedance of the transmission line. The matching section of the antenna matches the input impedance of the antenna to the line. In this unusual but perfect condition there are no standing waves.

Under this condition the losses in the line are caused by the resistance of the conductors of the transmission line and the rf leakage across the dielectric. These figures are easily obtainable.

In Fig. 2 we have a situation that is much more common. The antenna is not matched to the line. The line is terminated in a value of impedance other than its characteristic impedance. This could be caused by improper adjustment of the matching network. It could also be from operating at a frequency other than that for which the antenna was tuned, or, as in a great many cases, the matching network may not have sufficient range to match the antenna at the frequency at which it is being used.

If the antenna impedance was different than the characteristic impedance of the line but still resistive (a very unlikely case), the standing waves on the line would look something like Fig. 3. The solid line indicates voltage variations and the dotted line indicates current variations. You will note that the phase relationship between the voltage and current nodes is always 90°. The direction, as shown in Fig. 3, is determined by the value of load resistance. This is not a normal case. Normally the phase relationship would be some figure other than 90°, and if the termination were not resistive, this departure would be greater.

Let's look at these figures for a moment and see what they tell us.

Losses: At a current loop (the points of maximum current) the increase in current flowing in the conductors causes a loss due to dc resistance. At a voltage loop, the increase in voltage causes increases in loss through additional dielectric heating.

Impedance: The effective impedance changes as you progress, being maximum at a voltage loop and minimum at a current loop.

Breakdown: Thin conductors will burn out at a current loop. Closely spaced conductors will arc over at a voltage loop.

The losses due to swr are relatively unimportant other than at high VHF or UHF frequencies. In the high frequency bands the cause of a high swr will usually affect

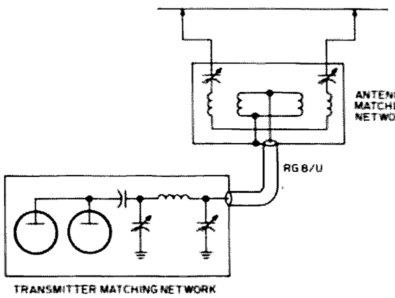

Fig. 1.

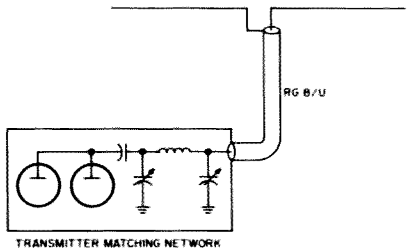

Fig. 2.

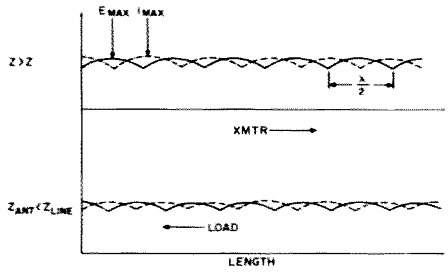

Fig. 3.

the system more than the losses in the line.

The impedance at the output connection of the transmitter, however, is extremely important. Most modern linear amplifiers do not have the ability to match a load different than their design impedance. The impedance presented to the transmitter is not the impedance of the antenna or that of the transmission line, but some other value depending on the degree of mismatch and the line length. You can see from this that in the case of moderate mismatch conditions it is possible to use the transmission line as a matching transformer, adjusting its length until the transmitter output circuit will properly match it. This, however, is a very limited and dangerous method. A number of current and voltage ratios combined with reactive elements can look good on the plate meter but cause excessive voltages across the loading capacitors of the transmitter. If you are having trouble with arcing in your amplifier, this could be the reason.

The insertion of an antenna tuner at this point will eliminate amplifier problems, but don't forget those high rf voltage problems – you have merely transferred them to the tuner. One other point: An antenna tuner will help the transmitter by providing it with a load it can match, but it does not help a poorly matched antenna and will not change the losses in the feedline.

Here are a few considerations:

1.If you were using a dipole antenna in outer space and feeding it with 50 Ohm cable, your swr would be 1.4:1. If, like mine, it is near the ground, it will be something else depending on the height and characteristics of the ground and surrounding objects.

2.The electrical length of the antenna will vary depending on the existence of nearby objects and its height above ground. This is particularly true of inverted vee type antennas.

3.If you cannot get an swr less than 1.5 on low frequency antennas, there is something wrong with the antenna.

4.On a wire antenna or a close spaced yagi antenna, do not expect a reasonable swr more than 25 kHz from the resonant frequency of the antenna.

5.Poor connections at the antenna are more common reasons for arcing than high swr. Solder all connections and wrap with plastic tape to protect from the weather. A sealant such as General Electric RTV is excellent.

6.Do not use your match box to cover up a poor antenna design; you are only kidding yourself. ■

more, if I have to.

In fact, as I sit here and think of it, I wouldn't be opposed to acting as a complaint department for other hams. Tell 'em to write to me, Wayne, and I'll start case files. I have learned a lot by dealing with Trigger.

Steve Rossi WA1WGS
East Wareham MA

UPGRADE

You've tricked me into it again! I've got to write and try to answer something in the November issue.

You've asked about Technicians and 10 meters, and you've left-handedly implied that Techs should upgrade if they want to use 10. What prompts me to write is that your sentiments seem to parallel very closely those of many long-time hams of my acquaintance, namely that the name of the game is upgrade, and the name of that game is code speed. I want to try to point out an alternative to this circle.

Out there among my fellow amateurs, I'm sure there are those who feel exactly the way I do about it. I have no quarrel with upgrading except that to upgrade I must increase my code speed. Before I became a ham, I argued against code altogether, and I realize that I was wrong. Code serves a useful purpose for all hams and prospective hams. Where we differ is: "How much?" The proposals in the restructuring docket did contain one premise which I consider quite valuable, namely, advancement from Technician *without increased code speed.* I am proposing a new class of license, featuring Advanced class theory and 5 wpm code.

I personally have no interest in DXing the world on the low bands, or for DXing the states, counties or whatever. I work VHF for two primary reasons, both of which are because of its restricted range under usual conditions. First, there is the opportunity to meet most of the people I talk to, and second, DXing to any distance is a real challenge.

For some 15+ years, I have done my DXing *only* on the broadcast band (.54-1.6 MHz) and have heard 47 states and over 100 BCB countries (not to be confused with ham countries, by which count I'd have at least 20 more, or geo-political countries, of which I'd have about the same amount less). For these years, my SWL friends have badgered me almost constantly about how it was easier on SW and how I should do it that way. I don't want it that way, because of the challenge of overcoming the real obstacles presented by stations which are not designed or intended to reach across the globe. I have been actively a member and officer of the National Radio Club toward this end. (Info, write NRC Membership Ctr., Box 118, Poquonock CT 06064, if I may put in a plug.)

I am interested in antennas, and in propagation both on BCB and VHF, and would like to upgrade, but since I'll likely never use low bands or CW, I don't want to spend my hobby time beating out the code. I don't expect everyone to agree, and I might even change my mind, but let's let ham radio diversify itself even more, and cater to a wider variety of interests. In the light of your continued emphasis on CB and computers which I simply don't find interesting, this shouldn't be too outlandish a suggestion.

By the way, let's also have some more Repeater Directory updates in the magazine!

Russell J. Edmunds WB2BJH
Kinnelon NJ

EBULLIENT?

First I must let you know that whoever spoke to me one Monday at about five thirty pm was, far above the call of duty, more helpful, intelligent, receptive, vivacious and just plain ebullient than just about anyone I have ever talked to in my 30 years of business. If she is anywhere comparable to the rest of your staff, I can see why you put out such a great magazine.

I have worked hard all my life as a hardware sort of person (bulldozer hardware), but have also built all sorts of things with varying success for my business, including an unfinished submarine!??!

About 2½ years ago when the economy began to fall apart, I said to myself, "Hey, what's happening?" Since then I have become, in my opinion, a budding financial hobbyist – which quite naturally led to commodity trading. However, it didn't take me long to find out that an up to the minute running account of prices was a necessity to help prevent disas-

Dirt Cheap Regulation

- - virtually freebee

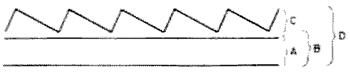

Fig. 1. (a) Reference voltage and regulator output voltage. (b) Minimum ripple voltage. (c) Ripple voltage. (d) Regulator input voltage.

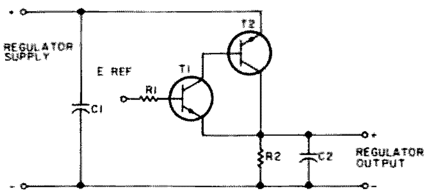

Fig. 2.

Entering the scene are transceivers, recorders and high fidelity radios, all operating on the approximately 13 volts of a car. On checking the catalog, you'll find you can expect to pay an additional thirty to fifty dollars so that you can use the same device in your home.

Although a number of regulated power supply circuits have recently been published, all have required specialized components, some of which may be available only through mail order. Here is a circuit which any ham or electronics enthusiast, who has accumulated the usual collection of unidentified transistors, diodes, resistors, and capacitors (who, in short, has the average junk box) can build a good quality regulated power supply cheaply and in a short amount of time. This regulator can provide either fixed or variable voltage as desired from either a transformer-rectifier dc source or an ordinary car battery charger.

This regulator consists of an NPN transistor in common base configuration and a PNP power transistor in common emitter configuration. The current gain of the transistor pair is the product of the gain of each of the transistors but the feedback is such that the voltage gain is unity. As a result, the output voltage of the regulator is almost exactly equal to the reference voltage. If the reference voltage is pure dc, the output voltage will also be dc and independent of the regulator supply voltage so long as the reference voltage is less than the minimal ripple voltage (Fig. 1).

The basic circuit of the regulator is as shown in Fig. 2.

T1 can be practically any NPN transistor and can be identified with an ohmmeter because the base collector and base emitter resistances of an NPN transistor will be low when the positive lead of the meter is connected to the base. Conversely, the resistances will be high when the negative lead is connected to the base. T2 should be a PNP power transistor mounted on an adequate heat sink. Most can handle a collector current of two to three Amperes. It can be identified, as it will have a low resistance between the base and either the collector or emitter with the negative terminal of the ohmmeter connected to the base.

The only moderately critical part in this circuit is C1. This capacitor should be large enough that the ripple voltage minimum is greater than the reference voltage by two or three volts. See Fig. 1(b).

Maximum ripple = rms input x 1.5 - 2.5 - regulator output voltage
or
= peak input voltage - 2.5 - regulator output

Thomas A. Reilly, M.D. W3GAT/2
32-25 88th St., Apt. 608
Jackson Heights NY 11369

C1 must have a value greater than:

$$\frac{\text{load current}}{120 \times \text{ripple voltage}}$$

where C is in farads.

C2 is optional but it can improve the transient current regulation if the load current varies widely, as occurs in class B power amplifiers. It can have a value anywhere in the range of 50 to 500 uF.

R1 should have a value between 10k and 20k and it simply limits the emitter base current of T1 should the reference voltage be present and the regulator supply voltage be off. R2 should be used either if C2 is used or if there will be times when the regulator will not be loaded. Select a value so that the current is between 1/10 and 1/20 the maximum current output of the regulator.

There are a number of methods to provide a reference voltage, and all are adequate. Remember that the quality of the reference is directly reflected in the output of the regulator.

Fig. 3 shows three methods to supply a reference voltage. Fig. 3(a) shows a zener diode reference supply. R3 should limit the zener current to about 5 mA. If C3 is larger than 500 uF the reference voltage ripple will be less than 10 millivolts. (This can be calculated with the formula used above.) Fig. 3(b) is a poor man's voltage reference. Each forward biased silicon diode will drop about 0.7 volts. So use as many as you need. Fig. 3(c) indicates a simple method to provide a variable output voltage from the regulator.

After the regulator is constructed, check the output voltage with the reference. They should be the same. If the output voltage is higher, open the base circuit of T2. The output voltage should then drop below the reference. If it does not, try another PNP transistor. If, on the other hand, the output voltage is low, there is a possibility that T1 should be replaced.

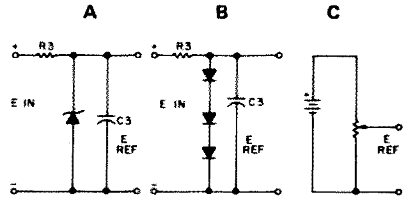

Fig. 3. (a) Zener, fixed voltage. (b) Diode, fixed voltage. (c) Variable voltage.

The voltage supply to this regulator is unfiltered dc and can most easily be obtained from an automotive battery charger, but a transformer with a full wave bridge or a full wave rectifier with sufficient voltage and current capability is fine.

I used a battery charger for a rectified ac supply which had an rms voltage of 13. The values of the components I used were: C1 – 2000 uF; C2 – not used; C3 – 500 uF; R1 – 10k, R2 – not used; R3 – 570 Ohms. With these values the regulator supplied 12.2 volts at 1.2 Amps, with a ripple of 30 millivolts. The heat sink is a piece of scrap aluminum 0.25 x 3 x 8 cm.

With a little imagination any voltage and current can be provided. There is no short circuit protection, but replacement transistors should be readily available in the junk box. So dig into your pile of unused and unidentified goodies, heat up your soldering iron, and spend a quiet hour building your brand new freebee voltage regulator. ■

LETTERS

from page 157

trous losses. A letter to the Chicago board of trade revealed that they sent out their price information using a strange 6 level Baudot code over the telegraph. To quote Ayn Rand – *"Somehow"* this has to be displayed on a TV screen. For several months now I have been building a computer somewhat based on an Altair-type bus, and after reading your editorial about Morrow the Genius, it clinched my thoughts about buying his CPU and front panel (Altair) combined.

I've read the *Bug Books*, *Martin's Computer Design*, the Osborn books and a lot of other stuff (magazines, etc.), but still do not know how I'll make that 20 mA loop signal appear on a screen or a printer or – hold your hat – appear in the form of charts on a plotter or graphics screen. Do people really do these things with computers?

I've *got to* do this, so maybe your magazine, with the right software stuff, may help. I'm not smart enough to take one of your *73* articles about Morse to ASCII and make a 6 level Baudot to ASCII converter or even figure out how the computer can tell the end of one code letter or number and the beginning of the next.

I could have bought a microprocessor all built for what I've spent on mine, but I do have a pretty good idea of how it works, anyway.

I may as well mention a few suppliers who were less than perfect:

Mini Micro Mart – After many phone calls, sent me a Univac printer (3 months), which I am not sure I'll be able to use (my own incompetence) $450.00 (Model 0769).

Processor Technology – Sol terminal board not received yet; ordered in July ($40.00) after I sent practically all over the world to obtain most of the parts. They wrote and said it would be redesigned, but they forgot me, I guess.

ARB Limited, Arizona – Sent them about $50.00 for parts, not yet received (even though he called me up on the phone – seemed like a nice guy, too).

Pet Peeve – suppliers who do not refund excess money but send a credit slip which I usually lose.

Arthur E. Bradford
Weymouth MA

LIMARC PR

"Welcome to the Wide World of Amateur Radio." With these words, narrated by the well-known CBS newsman Douglas Edwards, each Friday evening the listeners of WBAU (Garden City NY) are treated to a glimpse of what amateur radio is all about. In a pioneering effort, LIMARC (the Long Island Mobile Amateur Radio Club) has taken to the commercial FM bands to sell amateur radio to the general public. Produced and directed by Harvey Hurwitz WA2HYS and Steve Mendelsohn WA2DHF, the broadcasts attempt to provide some incentive for CB users to take that extra little step upward, and to alert the general public to the fact that there is a difference between the two services. Utilizing the studios of WBAU, located at Adelphi University in Garden City, these fifteen minute programs consist of group discussions about amateur radio versus CB, technical aspects of being an amateur, and how to find a course or the study materials required to upgrade from CB to ham. Most importantly, it highlights the differences between the two services in capabilities, scope, cost and basic requirements. No attempt is being made to downgrade the citizens band or hold it up to ridicule. We do, however, indicate by actual on-the-air recordings how different these worlds can be; for example, channel 19 compared to the local FM repeater on two meters. Short informative lectures on AMSAT, slow scan, ATV and similar subjects are given from a very light technical point of view in order to point up the vast differences between the two services. A debate was aired between an avid CB enthusiast and a group of hams with excellent results in the final on-the-air version.

One of the glaring omissions in the world of amateur radio is the critical lack of publicity. Unfortunately, this has led to many erroneous identifications in the news media where anyone with a radio was automatically called a ham. Listening to the various bands, one may often hear a tirade about the use of CB radio and its users. We must, however, face the unalterable fact that CB users outnumber hams by a staggering percentage. These numbers do constitute a vast reservoir of potential amateurs and, if the truth be known, many of our CB haters were in fact CB operators years ago. The use of the big stick technique is obviously useless, so we at LIMARC have taken this opportunity to use the soft sell. If it works for toothpaste, it should work for amateur radio. One of the local cable TV

A Vest Pocket QRP Rig

-- if you have a big one

"Simplify, simplify" was Henry David Thoreau's formula for a better life.

His philosophy came to mind recently while I was fumbling with some wires, cables, antenna switches, transceivers, antenna tuners, swr bridges and assorted other trappings of the ham radio hobby. Complexities are challenging sometimes, and often great fun. But they can be frustrating bores, too.

Proof is everywhere that ham radio is both progressing and becoming considerably more complex: digital readout transceivers, computerized CW keying machines, autopatches, slow scan television consoles, el-az mountings for OSCAR and EME antennas . . . sophisticated stuff when you consider where it all got started.

Can you imagine people actually communicating with *sparks*? And cat's whiskers and hunks of galena?

As I type this, I am flush with a victory for simplicity. I have just wired a tiny transistor to a crystal, three resistors and a few capacitors, made the little rig oscillate, and carried on a three-way QSO for over an hour through heavy QRM. I have just worked 400 miles with one-half Watt and a dipole that's only 15 feet high. I feel a bit like Marconi must have felt when he spanned the Atlantic for the first time. I called CQ with a piece of silicon and a hunk of quartz and two stations answered.

Simplify. I pulled out my junk box last night with the urge to build the simplest transmitter I could put on the air. It is not a marvel of engineering; it is not even a technological breakthrough. It's basic radio, and if I had my way, there would be a special ham band for basic radios and QRP wonders. As I type this, I have just tried to answer a CQ and been stomped flat by a kilowatt.

There is nothing complicated about this project. A 2N2222, available for as little as a dime, is used in a conventional crystal oscillator circuit. The oscillator is link-coupled to a low pass filter and a well-matched dipole, and that's it. The usual rules apply: Keep leads reasonably short, don't use a big soldering iron on the 2N2222, and listen to your signal to be sure you aren't chirping. Output tuning is a bit broad, so adjust C1 for best keying, even if it means giving up a few milliwatts.

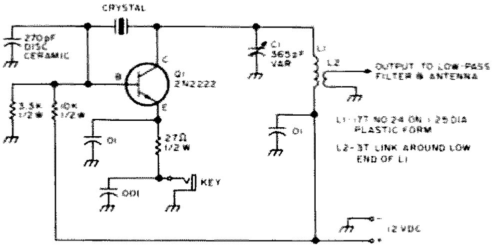

Fig. 1. Schematic. L1 — 17 turns #24 on 1¼" dia. plastic form. L2 — 3 turn link around low end of L1. C1 — 365 pF variable capacitor.

Early mornings and daytime seem best for QRP work on 40 meters. Add two or three turns to the coil if you want to work both 80 and 40. Or add a switch and a 75 pF capacitor across C1. At 12 volts, my version draws about 45 milliamperes. The 2N2222 will get warm if the key is held down for extended periods. Warm is okay, but hot is not. Got it?

As I type this, I have just worked Tennessee — 500 miles with a 569 signal report — at high noon. Nobody believes I'm running just one transistor . . . ■

Where You Can't Solder or Weld

- - joining dissimilar metals

About eleven years ago a close neighbor in Washington, D.C., complained of TVI several months after she purchased a new TV set. The trouble was completely cured for the time being when her husband and son-in-law took down the old antenna and cleaned all contacts on it as well as both ends of the lead-in.

On another occasion, my all-metal 20 meter quad with aluminum tube inserts (see May, 1969, *73 Magazine*) started acting up after a few months. A resistance reading through 100 feet RG8-U feeder and the quad's driven element showed a variation from pure or normal resistance for that length, at one moment, to all the way to infinity over a brief period while a normal breeze was blowing.

How often have you read or heard of adjusting the element length of a home brew beam by shoving the shorter aluminum tubing further into the end of the main tubing until the desired overall length was obtained, with nothing more than a clamp or self-seating screw to hold it in place?

Then, too, have you not at one time or another been plagued with rectification in one of your antenna systems, particularly where aluminum and copper are used?

Scraping the enamel or other factory-applied coating off copper wire used for quads beyond the point where soldering is necessary causes oxidation or corrosion on the scraped surface, particularly down here in coastal Florida where the air contains salt spray. This is said to interfere with rf, which travels on the surface of the wire. Even power line insulators during a prolonged drought as we had in 1967 can keep you guessing temporarily as to the cause of poor reception until a good shower cleans the insulators not otherwise defective.

This article is intended to help you correct at least one source of trouble – one which involves the use of *incompatible metals* such as copper and aluminum.

Some years ago, while "reading the mail," a fellow was heard to say that his backyard was full of TV antennas which he had removed on service calls and found it necessary to replace with new material. On this point, it is a fact that there is a vast difference between the 12 foot lengths of aluminum tubing of different diameters and wall thickness purchased from a well-known supplier in Washington, D.C., and the comparatively poor material in use on many antennas, whether for amateur use or TV. Down here, TV antennas are mostly anodized on the outside at least, to prevent or hinder oxidation and/or corrosion in the salt air, but amateur beam antennas are not.

In 1953 Mike A. Miller, Assistant Chief of the Process Metallurgy Division of the Aluminum Research Laboratories, New Kensington, Pa., delivered a paper at the National Spring Meeting, AWS, Houston, Texas, entitled "Joining Aluminum to Other Metals." He discussed methods of joining aluminum to other metals by fusion welding, pressure welding, brazing, soldering, diffusion welding and resin bonding. The article's abstract states in part that aluminum can be joined to a large number of other metals by various methods. The joining method chosen will depend on the metal to be joined to aluminum, the design of the parts, the permissible temperatures of joining and on the service requirements of the completed assembly.

A lot of the foregoing may be of little interest to the average ham. Although Miller said aluminum and copper may be joined for electrical applications by employing a special arc-welding technique, several telephone calls to the Baltimore firm from whom the above-mentioned paper was obtained elicited a far more simple method for use by us hams (see Fig. 1).

Fig. 1 illustrates graphically the method of joining an aluminum tuning element that is telescoped or slid into the main tube. It is suggested that you first insert E, a wood dowel, into the end of the inner section to prevent a concave surface under pressure. Then slide the tuning element F into the main tube G to arrive at the resonant frequency desired. Drill holes at A through E, F and G to permit insertion of 6/32 nickel-plated steel bolts as indicated. A copper strip, with a similar hole at each end, is then tinned at its ends, including the inside edges of the holes, and placed in position as shown at D. B, nickel-plated steel washers, are then placed above and below the holes in the plated or tinned copper strip, and the assembly fastened securely with the nickel-plated steel bolts, A, and similar nuts, C. Of course, the "contact surfaces" of the aluminum tubing must previously have been burnished or cleaned. All that remains now is to cover the joint with Amphenol silicone compound or other suitable

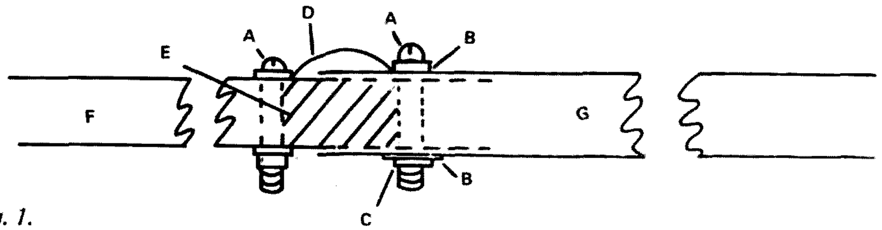

Fig. 1.

"goo" to exclude oxygen, whether from air, dew or rain.

Coax terminals at the feedpoint of a beam (see Fig. 2) are joined similarly except that the copper center conductor and the shield are substituted for the copper strip. Remember that, in Fig. 1 and Fig. 2, *no part* of the untinned copper must come in contact with the joint as illustrated, and nickel-plated steel washers are used on *both sides* of the tinned copper.

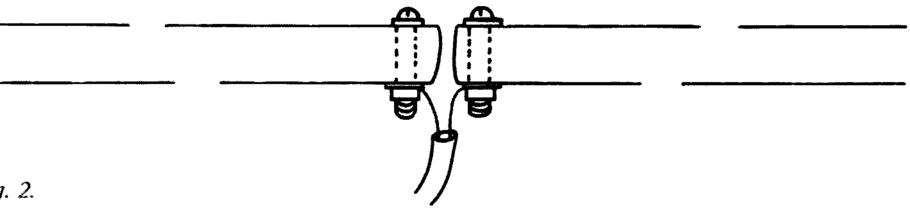

Fig. 2.

If your quad antenna uses beryllium copper wire, a better job is accomplished if the copper is silver-soldered instead of being tinned.

Aluminum or "clothesline wire" used for dipoles, fed with copper leads, are joined as in Fig. 2. Mash the ends of the aluminum wire flat; insert ends in a good vise. First drill a hole with a smaller size drill, and then enlarge the hole with a drill to take the 6/32 bolts referred to above. And don't forget the "coating."

If you are a DX hound, your antenna connections play a most important role in the power you "put out" as well as in the signals you hope to capture. ■

LETTERS

from page 159

channels has started to run these tapes on Wednesday evenings at 6:30 pm. Unlike many public service programs supplied to these stations by various sources, they have chosen to give the "Wide World of Amateur Radio" prime time, as they feel that with the high potential interest in radio communications, many CB operators will be listening at these hours. All participating stations have been warned that these tapes can only be used as a non-sponsored public service broadcast and the local amateurs have been warned that replay of these tapes or recordings made on the air can not be done on the ham bands.

Production of these shows requires the services of the WBAU studios with Bruce Barlow manning the board. A typical session will produce thirty to forty-five minutes of tape. This tape is then edited down to one or two fifteen minute shows. Our thanks go to Doug Edwards, who so kindly offered to record the open and close of each show. Editing is done at the studios of CBS New York, and we thank them for their assistance in making these shows possible. Logistically, the major difficulties involved are those of having a studio available, transporting the necessary participants to and from the studios, editing the tapes and making the necessary duplicates and getting the tape to the station on time. Being committed to a minimum of sixteen weekly shows, we have at this writing completed and aired seven shows and three are ready to go. It has been a difficult and sometimes trying experience, but we at LIMARC feel that proper exposure and adequate publicity can do nothing but help amateur radio.

Harvey Hurwitz WA2HYS
Oceanside NY

MORE JAMMING

I'm a Novice, and I've got a message for all you others who operate in the Novice bands: QUIT JAMMING!!!! Whenever I hear someone CQing, about the time I hear the guy identifying, I hear someone CQing almost right on top of him. That's not only bad procedure, that's stupidity! Some of you guys who don't venture into the Novice bands very much – go there sometime and you'll find out what I mean. You'll hear some guys CQing right on top of him and you'll never know who he was.

When I was studying for my Novice license, I knew about antennas, what frequencies I could use, and all that stuff except one thing: procedure. I didn't know how to use SK, AR, or what to say after the other guy handed it over to you. And then there are these guys who CQ anywhere without listening, usually jamming a DX QSO or trying to get the DX at somebody else's expense. And many of the League publications have been very vague about this. So, you guys, whoever's doing this, please give us guys who don't do this jamming a chance to get a decent QSO. *It ain't every man for himself, you know.*

ONE VOTE

Keep meaning to write, but it seems like I am always too busy.

Re your I/O Editorial in October *73:* one vote for the I/O section. I do not now own a computer; however, I do hope to as soon as I find the time to get more involved. The I/O section makes me feel like I am keeping in touch; I do learn from it, and I certainly do feel that computers are a part of hamming. There will always be newcomers to hamming, hopefully, so one more big vote for the basics, i.e., what size resistor do I want to use here or why, and how do I compute what size capacitor to use there and, hopefully, just as basic material about computing. I do also enjoy the advanced articles.

I am a WW II pilot who still earns his living flying, and would like to take this opportunity to tell you how much I have enjoyed Mr. W. Sanger Green's articles, the "Autobiography of an Ancient Aviator."

Keep up the fine work; we're out here even if we don't write too often.

John G. Bilotta WA1PMK
Naugatuck CT

CRUDE, BUT NICE

I enjoyed very much your article on Tesla in the November issue. I have been trying to find some information on him, so the bibliography alone was worth the price of the magazine.

I would also like to pass on a rather crude indirect comment relative to your *Advanced Class Study Guide* made by an FCC engineer. I read the *Guide* over twice before taking my exam, and when the examiner told me that I had passed, he said "Man, you must have studied your ass off." Quite a compliment to me and *73.*

David M. Gray, Jr. WB5NZF
Moreauville LA

NOVICE HELP

I usually don't make an issue of subscribing to a mag by writing a letter, but I would like you to know I learned 5 wpm from one of your tapes I purchased in Medford, Mass. at Tufts Radio store a year ago July while on vacation in the east. It made it possible for me to get my Novice ticket, and I was wondering just the other day where I could get another one of your tapes. Hope I can do as well with it as the 5 wpm tape I learned from.

Paul E. Taylor WB9VCI
Monroeville IN

MMM

In your December, 1976, issue of *73,* page 119, you criticize Mini Micro Mart. I wish to disagree with you. I had sent in a sixty-nine dollar order for many books they offer and a keyboard which cost $27.00. This keyboard is fully ASCII encoded, case enclosed, with numerous other display switches and worth much more than their asking price.

All I'm saying is that *M.M.M.* had no problems with my order and I'll do business with them again. They seem to have no problems whatsoever.

Art Surges
Evergreen Park IL

SATISFIED

Well, I hope you're satisfied, Wayne. Even though I let my Technician ticket lapse eight years ago (I'm not much of a talker), I kept up my subscription to *73.* You kept pounding at me with 2m FM, repeaters and such. You urged me to buy your study guides and your code tapes. I just got back from the Federal Building, downtown Chicago, having easily passed the exams for my new Tech ticket. I hope you're satisfied. I am!

Chuck Neuman
Skokie IL

WHICH uP?

Congratulations on your new magazine, for which I have enclosed a subscription. I talked with you when you were in Jordan and also when you were in FO8 as well as several times on 20 meters when I lived in Oakland.

I just got started getting into computers. Thought the Kim 2 looked pretty good; however, thought I would wait for your magazine and get the information about many of the others.

My very best wishes for your continued success and good health.

Exciting New Touchtone IC

-- make phone calls with your HT

After many tries and an equal number of failures to get the rf out of my MH8900 chip, I had just about given up on using the beautiful Chromerics keyboard which I had optimistically mounted on my rig. Then I saw the specs on the MC14410 chip. Too good to be true!

I sent off to Data Signal, Inc., for the chip, printed circuit board and components. The Data Signal circuit is shown in my diagram in the dotted lines. This is a great combination, and is so small that it will fit almost any corner of most rigs (lots of room even with the large crystal in my Wilson HT).

To keep a short story short, I wired up the board, installed it, and it worked. There was adequate drive for full deviation and the first attempt brought up the autopatch. So far so good.

Now, how to automatically key the transmitter when a key is depressed. Everyone who has operated mobile has had the mike cord wrapped around the steering wheel at some embarrassing time. You just can't drive, push buttons and key a mike all at once! After a voltmeter, mA meter and scope check of the entire circuit, there was no apparent place to obtain a good reliable indicator that a key has been depressed.

Enter the ubiquitous 741, the problem solver where all else fails. The 741 is stabilized in the off condition via R7, R8, and R9. A small tone signal is picked off the original circuit at the junction of the two 3.9k resistors and coupled to pin 3 of the 741 by the .01 ceramic cap. When a key is depressed, the 741 amplifies the tone and converts it into a series of plus 12 volt pulses. These are rectified by the diode which pumps the 2.2 uF electrolytic cap. This in turn switches on the NPN transistor, picking the relay. The 2.2 uF cap determines the hold on time for the transmitter. Leakage of the cap and other components eliminates the need for R11.

Adjustments

The only adjustments required are the selection of the electrolytic capacitor (I used 2.2 uF) to determine the "hold on" time of the transmitter, and the adjustment of R5. To adjust R5, put a voltmeter on pin 6 of the 741 and find the point where the 741 turns off with no signal (no key depressed) applied. Gradually go in the off direction while depressing a key. The point where the 741 remains off with the key depressed is the low limit. Set the pot half way between the no signal off point and the key depressed off point for best reliability.

R6 was added to take some of the load off the zener diode when used for mobile operation. The regulated 5.1 volts is used to bias the 741 to assure more stable operation. ■

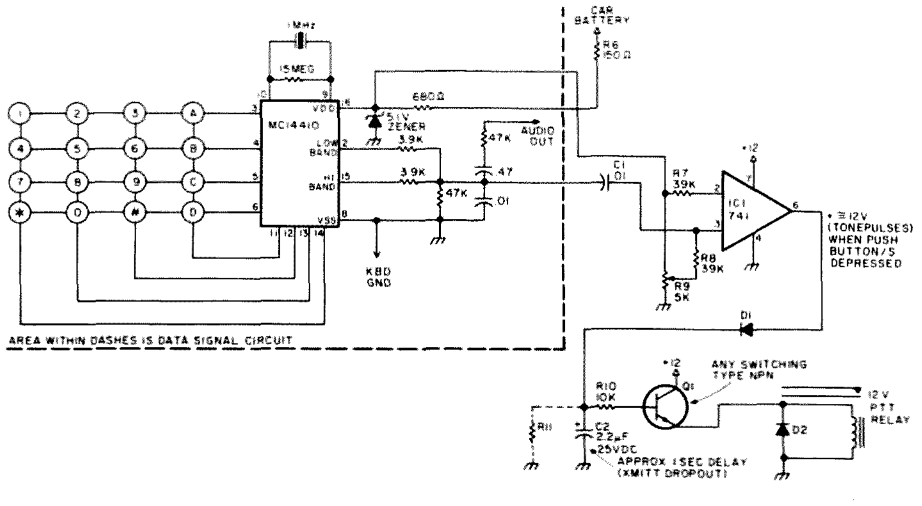

Fig. 1. Touchtone automatic keying circuit (transmitter) for the MC14410 chip. All resistors ¼ Watt.

Parts List

R6 — 150 Ohm ¼ Watt
R7, 8 — 39k Ohm ¼ Watt
R9 — 5k multi-turn trim pot
R10 — 10k Ohm ¼ Watt
C1 — .01 uF 10 V ceramic
C2 — 2.2 uF 25 V dc electrolytic
D1, 2 — 1N4001 or equiv. (not critical)
Q1 — 2N3567 NPN (any switching NPN which will carry the relay current will work)
1C1 — 741 op amp

Revisiting the COR

-- improvements on the April '76 model

William Hosking W7JSW
8626 E. Clarendon
Scottsdale AZ 85251

The circuit I presented in the April, 1976, issue of *73 Magazine* worked just fine for me for six or eight months, but then my ham instinct to "add on" overcame my better judgment and I decided to improve the system. During that eight month period I had jury-rigged an identifier keying circuit on the original COR to key an identifier I had built. I wanted to clean up that rat's nest and add some features such as adjustable dropout delay to the COR so modification of the original became a necessity.

Features

In the revised unit, I wanted some extra features. These included dropout delay, transmitter time-out, control inhibit, and extra keying contacts for such uses as an identifier. I also decided, as long as I was about it, that I would put the whole mess on plug-in circuit boards and bring controls for the above delays and times out to the front panel.

Circuit

The revised circuit is shown in Fig. 1. The original relay is now replaced with a NOR gate, U1A. The input to U1A from the COR also triggers monostable U2 on the trailing edge. The output of U2 then goes back to the input of U1A and keeps its output low for a short time after COR release. This time period is adjustable and on mine is a front panel control. The 1 uF capacitor on U2 will be covered later in the article.

The second part of U1, U1B, uses the output of U1A and a low (ground) on the control line to produce a high on its output. The high output of U1B drives relay RY1 and also an LED indicator (optional). I use the relay contacts for PTT, ID key, and other uses.

Diode D1 and SCR Q5 are the active elements of the time-out circuit. D1 is present because the SCR I had would not turn Q4 off completely. Transistor Q5 is driven from U1A, which is high when no signal is present (squelched). This turns Q5 on and prevents C4 from charging. When the receiver unsquelches, Q5 turns off and C4 charges until Q7 turns on, which in turn opens the PTT relay. With the values shown, the time-out should be adjustable from about 50 seconds to about 3 minutes.

One more circuit is added, and that is Q6. Q6 is driven from the keying output of my IDer and turns the PTT relay on without triggering the COR or timer circuits.

Operation

I put the above circuit all together on the bench and it worked perfectly. I then built it on plug-in circuit boards and, wonder of wonders, it still worked. I then mounted that board and the identifier I had built in a logic rack on a new repeater panel recently built. I hooked up all the lines, powered the beast up and – ouch! – every time I keyed it up, it would retrigger itself every few seconds until I hit the control inhibit. It just sat there going click . . . click . . . click . . . ad infinitum.

I immediately took the standard TTL logic fixup mode. I put .01 uF capacitors on every chip and on every line that I possibly thought could help. To make a long story sad and short . . . it didn't work.

To make a short story out of several days of gloom and despair, I finally cured the problem entirely by accident. I accidently shorted a 1 uF capacitor from the timing pin on U2 (pin 14) to ground, and the problem went away. Although I had fears of drastically altering the timing, I still hung the 1 uF there and proceeded to test. Repeated tests indicated that the original problem had gone away and the timing had not been changed.

Conclusion

The circuit of Fig. 1 is now part of a control rack which contains the COR/PTT circuits, my IDer, and some audio interface circuits in addition to the control decoders. Fig. 2 shows the

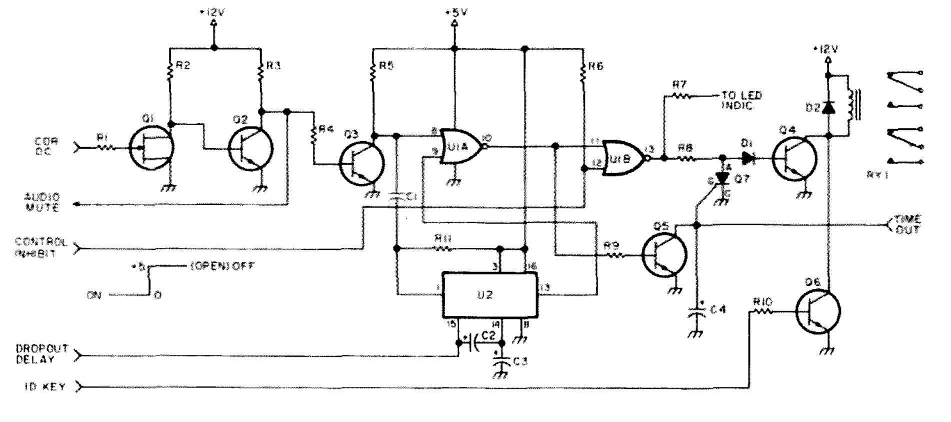

Fig. 1. Complete circuit of the COR/TIMER. The circuit requires a ground on "control inhibit" to operate. "Audio Mute" goes back to my audio interface board to shut off the audio during the dropout delay.

front panel controls I used.

Although I put mine on a multi-purpose, plug-in circuit card, I did design a printed circuit board for the circuit and they can be obtained from CONTACT R&D, 35 W. Fairmont Drive, Tempe AZ 85281 for $4.95 ppd. Also I am preparing a plug-in circuit board for the COR plus a single function tone control which should be ready by the time this gets published. Write to CONTACT for details. ■

Fig. 2. Front panel controls. These can be put on the board if desired.

EDITORIAL BY WAYNE GREEN

from page 4

to get every club member to work a mention of the special guest into his contacts, not only for the chap he is talking with to hear, but for all local listeners. Some clubs have had great success with phone canvasses of every ham in the area, for getting them out to a special meeting is the first step toward getting them to join the club.

WHAT TO ADVERTISE

Just saying that some joker is going to be there to speak isn't likely to get people out. You may think your speaker is famous, but the chances are that a lot of hams won't agree. As in all advertising, think in terms of what the benefits are to the chap you want to come. Will he be really entertained? Tell him so. Will he also learn a lot which will be of value to him? Tell him!

When I talk to ham clubs I tell a lot of things that I could never print in the magazine. Our lawyers won't even let me tell you what well-known ham firms we've been having serious troubles with, and what the problems are. You might just get a lot of inside dope on what is happening in amateur radio, not only with manufacturers and dealers, but with some of the ham magazines.

Some hams would like to know the real inside information on what is going on with the FCC, with the ARRL, with *CQ Magazine*, with the coming WARC, and things like that. I kind of hint around a bit about these in *73*, but at a club meeting I answer all questions . . . even questions about *73* and *Kilobaud*.

Find out what your speaker may be able to talk about to enthuse the listeners, and stress that in the PR. The above two paragraphs were merely by way of example – please don't ask *me* to come and talk. I try to plan my life so I can just barely, with a very few hours of sleep and a seven day week, get 90% of what I should do done, with no time allocated for talking. On the few occasions when I talk to a group, mostly at conventions, I make a tape . . . and copies of the tapes are available.

DOLLAR AN HOUR

A few old-timers may remember with nostalgia the days when someone making a dollar an hour wasn't doing all that badly. If you happen to know any of these chaps, wake them up and tell them that Wayne Green has figured out a way to get back to those good old days . . . back to a dollar an hour!

Heck, I was chief engineer of a thousand Watt broadcast station at one time and made 90¢ an hour. Fortunately I worked a 90 hour week, so it did mount up. And the 90 hour week left no time to spend any of the money, so I saved doubly and eventually was able to buy my freedom.

So how do we get back to a dollar an hour? Simplest thing in the world – all we have to do is change our day to 100 hours instead of 24. This will make decimal time possible and simplify watches. Sixty minutes in an hour is ridiculous – shame on you putting up with such a nutty system for all these years.

If we change to a 30 hour work day we'd make about $150 per week at a dollar an hour. That would be a slightly smaller percentage of our normal working time (the 8 hour day), but not a lot.

The next step would be to have 100 minutes per hour instead of 60. This would make a new minute last about 8½ seconds, which should be long enough for anyone. We might call them centihours, with millihours being 0.85 seconds long.

Oh well, if you're going to fight every new idea that comes up . . .

NOVICE MAGAZINES ACOMING?

Yes, yes, I've read that stuff about a "new" *CQ* . . . pardon me for being a bit jaded as far as "new" *CQ*s go . . . they seem to be periodic fantasies which quickly fade away . . . and I would have put the present circulation of the magazine at more like 7,500 than the 40,000 claimed . . . either way some changes won't hurt.

While there is a need for more articles for beginners, my own feeling is that beginners are just as interested as anyone else in the state of the art and developments in all of the 25 or so hobbies which make up amateur radio . . . thus while there is a need for more fundamental type articles in the ham magazines, I doubt that there is much of a need for whole magazines devoted to "run, Spot, run" level articles.

The major interest at *CQ* has been in CB for a long time now and, other than a fast hormone shot to ailing old *CQ*, I wonder how long any interest will hold up in their loser. Money talks, and *S9* is where the money is. We'll see.

Ham Radio magazine has also announced a Novice magazine, but I'll be surprised if this doesn't eventually become a section of *HR* and sort of fade away.

And not to leave any charges of favoritism, I must mention *QST* too, much as it goes against the grain. They've been doing some strange things down there in Newington recently . . . I write and ask them about it now and then, but they don't answer my letters. For instance, at conventions I've been getting a continuous barrage of visitors to the *73* booth volunteering that they have dropped their subscriptions to *QST*. And I know there is serious concern in Newington over this, complete with a questionnaire to readers asking what it is about *QST* that they don't like. Yet, on the other hand, *QST* has been claiming incredible increases in circulation . . . a puzzle. Things fell into place a bit when during the New Orleans ARRL Convention an official explained that *QST* was now sending two copies of the magazine free to 30,000 libraries.

The recent ARRL claims have been for 135,000 copies distributed, so 60,000 to libraries would leave 60,000 to members, 10,000 for radio stores and 5000 for back issue sales, almost exactly what I had estimated. They can afford to send a lot of copies for nothing because *QST* enjoys an incredibly low postal rate . . . around 2¢ a copy the last time I got the figures on it. I haven't checked the cost per copy for mailing *73* lately, but I do know we are paying 70¢ per copy for *Kilobaud* magazine, and it is only 144 pages as against 208 or so for *73*.

None of this is of any real significance to readers . . . what counts in the long run is whether the magazine is interesting and really worth the money it costs. If the new Novice magazines meet this requirement, they will sell well.

THE PLAYBOYS

I got some reports on the New Jersey Playboy Club ARRL Convention . . . one from a ham who went there . . . disappointed, said many people left early. Another from a ham dealer who said it was great . . . lots of people, and they were spending money . . . always a pleasant thing for dealers.

Several of the exhibitors got a rude shock when a man showed up demanding that they collect tax on all sales and give it to him before they left. Tufts stood up to the guy, pointing out that no tax was due on sales made by out-of-state vendors, unless they were licensed by the state. Out-of-state vendors can sell if they only come in once a year; otherwise, they are supposed to get a license and collect tax. The tax man shut up when this was explained, and went away . . . never to be seen again.

Word is that one exhibitor was merrily charging the tax anyway, and the suspicion is that they did not turn in this money to New Jersey. Tsk.

One hint to readers . . . if you find yourself being charged a sales tax by an exhibitor at a hamfest who is there from out of state, get a receipt for the tax and check with your state to make sure the money was turned in. While none of us like to pay a tax, we don't want to be ripped off for the money either.

The Mighty Magnet Mount Antenna

-- the price is right: zilch

George Hovorka WA1PDY
674 Brush Hill Rd.
Milton MA 02186

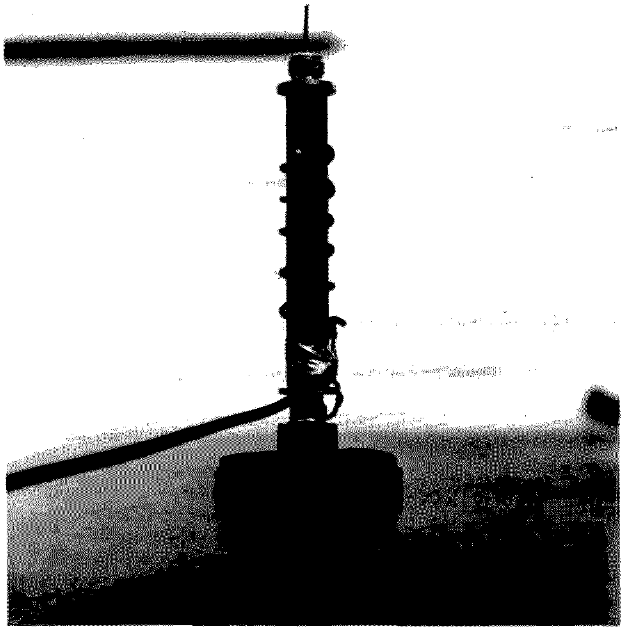
Here is a truly versatile magnetic mount two meter antenna that is easy to build. The heart of this antenna is the magnet, which must be able to retain its grip at high driving speeds and when low hanging branches hit the antenna. After some searching in my basement for a suitable magnet, I found a burned-out twelve inch loudspeaker. The speaker had originally been used in a rock and roll guitar amplifier and had a large 2½ lb. ceramic magnet. Such a speaker could be picked up gratis from any musical repair shop.

Assembling The Antenna

Before handling the magnet, remove your watch. Treat the magnet gently, since the ceramic is brittle like glass. Carefully remove the magnet assembly from the loudspeaker frame with a small cold chisel. Now remove the metal pole pieces that sandwich the magnet. These are usually lightly glued to the magnet and can be removed with the aid of a rubber hammer. The larger pole piece is turned over and glued to the top of the magnet with epoxy (see photo).

On the top of the magnet assembly, a loading coil is placed. I used an old high voltage insulator, but almost any insulating material such as phenolic, plastic rod or pipe will do. If copper pipe caps are epoxied to each end, this would form a suitable coil form. Another excellent coil form would be a large blown-out cartridge fuse which your local power company may be able to provide. The dimensions used are not too critical and can be anything from ¾ to 1¼ inches in diameter and about 8 inches high.

On this form 9 turns of #14 gauge copper wire is wound. The type of wire is not terribly critical and thinner wire could be used. As a radiating element, a 39 inch piece of coathanger or other stiff wire is used. For my antenna, I straightened



Close-up view of base and loading coil.

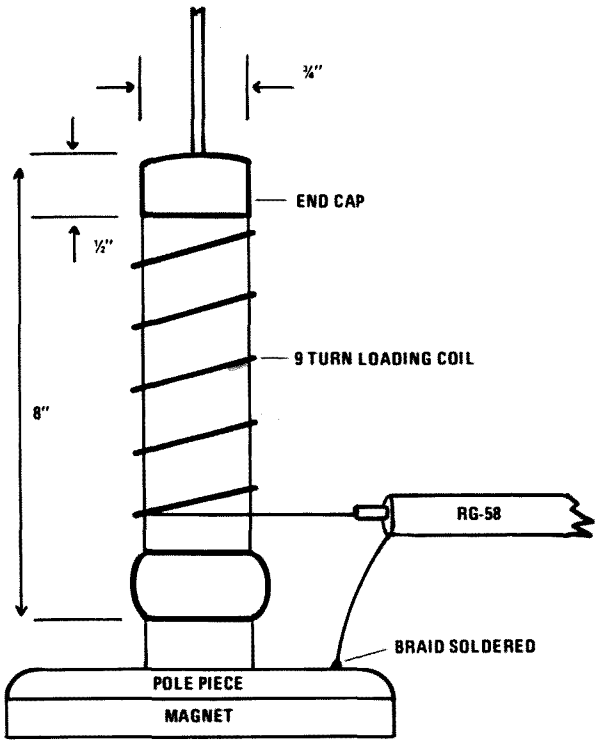


Fig. 1. Loading coil and base.

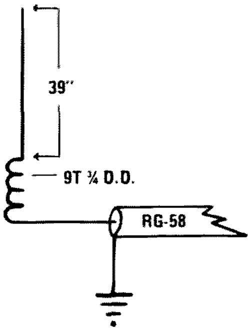

Fig. 2. Schematic diagram.

out a heavy coathanger in a vise and soldered it to the top cap. The coil assembly is now either soldered or epoxied to the metal base.

Finally a 14 foot length of RG-58 coaxial cable is connected to the antenna, with the inner conductor soldered to the bottom end of the loading coil. The outer braid is soldered to the pole piece with a large soldering iron. Alternatively, a hole could be drilled and tapped in the pole piece. The braid is then secured by means of a screw and lock-washer. As a final step, the exposed braid and inner conductor are sealed with silicone RTV to prevent water from seeping into the coax.

Tune-up

The completed antenna is now placed on a car roof or other large piece of sheet metal and the radiating element trimmed for lowest vswr. If a vswr meter is not available, cut the antenna to 39 inches in length, and as long as reasonably low power levels are used, the antenna should perform well. A good rule of thumb when testing any home brew antenna is to make sure that it receives correctly. Check it with an ohmmeter before firing rf into it.

Conclusion

My antenna, powered by the one Watt from a TR-22 and placed atop a 1960 Chevy, produced truly spectacular results. The WR1ABV machine in Boston could be hit solidly while driving through southern New Hampshire, at an airline distance of over 40 miles. Operating stationary mobile from Easton, New Hampshire, it was possible to hit the WR1AEA machine in northern Vermont with good results, a total air distance of 60 miles. I hope this antenna works as well for you as it has for me. Happy mobiling. ■

A 15.75 kHz Oscillator

- - simple TV test unit

This is to describe a device of considerable value to the many hams that service TVs either in the shop or at home. It has not, so far as I am aware, been used or suggested by anyone else. It is simply a regenerative receiver set on 15.75 kHz, the TV horizontal oscillator frequency.

With it the horizontal oscillator frequency can be set correctly without a signal and the adjustment made in seconds without any doubt as to whether to increase or decrease the oscillator frequency. Many of us have spent valuable time in the shop blindly turning the slug in and out without the slightest idea where it should be for the correct frequency. If the oscillator is not working, there will be no signal regardless of adjustment. Adjustment of the horizontal oscillator in the usual manner only brings the frequency near enough that the sync pulse can lock it in step and thus is no assurance that in the free-running state it is on frequency.

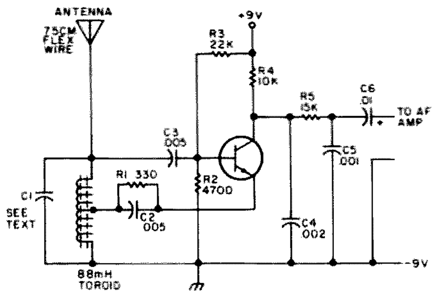

Fig. 1.

This receiver may be built into any small case such as that from a defunct transistor radio. Its variable condenser, audio amplifier and speaker may also be used if good. It may be made small enough to carry in a shirt pocket on house calls.

It is a simple project for you who are hams, but maybe not for those who only replace parts and consider radio a mystery. Not being entirely satisfied with the unit I have used for the last several years, and with this write-up in mind, I built another, per Fig. 1.

To conserve space and avoid hand capacity effect, an 88 mH toroid coil was used rather than a regular horizontal oscillator coil which would have required some shielding.

This circuit using the collector at ground potential for rf was chosen to simplify the audio takeoff. R5C5 provides additional filtering to keep rf out of the audio output. Use the audio amplifier in the original case, if convenient. If you must build your own, a small IC is suggested for compactness.

A regenerative receiver is most sensitive when not oscillating at full strength, so it is a good idea to use variable resistors to determine the best values for reliable but not excessive feedback, replacing them with the nearest fixed small resistors. While I used a 2N706 transistor, it is safe to assume that at least a hundred other types, requiring different bias resistors, etc., may do as well or even better.

C1 is made up of one or more fixed mica condensers in parallel with a small variable condenser or mica compression trimmer; the latter is definitely second choice. The total capacity required should be around .0018. Marked values are seldom correct. Temperature sensitive condensers are to be avoided for tuning. Silver micas are preferred. The temporary use of an external variable condenser of considerable capacity will expedite finding the proper value and frequency.

With this receiver's antenna near the horizontal area of an operating TV, listen for the 15.75 kHz signal when you are sure the receiver is oscillating. When zero-beat is obtained, with final tuning condensers in place in the final assembly, no further adjustment is required and it is ready for use.

With no signal or antenna on the TV to be serviced and with front panel control, if any, set at midrange, adjust the horizontal slug for zero-beat with the receiver and you are finished with that part of the job — no guesswork! If the sync doesn't take control, then that is a different problem, and there is no need to twiddle with the horizontal oscillator. ■

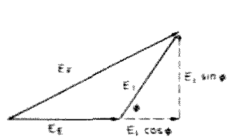
Behavior Mod for the HM-102

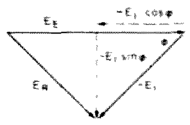
-- pretty simple

The Heathkit HM-102 swr bridge and power meter is an excellent swr indicator, and as an rf wattmeter it gives good results when the line in which it is used is a perfectly matched 50 Ohm line. Obviously this condition, if it occurs at all, will be present at only one specific frequency in a band, if the load is an antenna. The usefulness of the HM-102 as a wattmeter is therefore restricted by the fact that readings depart radically from true power if the swr in the 50 Ohm line is significantly different from unity. Furthermore, even in a matched line of some other impedance, the indicated reading is not true power being delivered to the load, but is so-called "forward" power from which "reflected" power must be subtracted to give a true power reading.

The HM-102 as assembled per Heath's instructions makes no provision for reading reflected power. However, it is possible with the rearrangement of a few components, some very slight surgery on the circuit board, and the addition of one .001 uF capacitor to provide for reading reflected power as well as forward power with the HM-102. This makes it possible to use it to determine the true power delivered to a load, regardless of swr or mismatch, on lines of any impedance.



$$E_F^2 = (E_E + E_I \cos\phi)^2 + E_I^2 \sin^2\phi$$
$$= E_E^2 + 2\,E_E\,E_I \cos\phi + E_I^2$$



$$E_R^2 = (E_E - \cos\phi)^2 + E_I^2 \sin^2\phi$$
$$= E_E^2 - 2E_EE_I \cos\phi + E_I^2$$

$$E_F^2 - E_R^2 = 4E_EE_I \cos\phi$$

Fig. 1. Vectorial addition of E_E and E_I in the forward power case, and of E_E and $-E_I$ in the reflected power case. The squaring is performed by the meter scale calibration, and the difference between the two scale readings is proportional to $EI \cos\phi$, the true power being delivered to the load.

Principles of Operation of the HM-102

In the HM-102, as in all typical directional rf wattmeters, the meter deflection for forward power or for setting swr sensitivity is proportional to the vector sum of two voltages. One of these is derived from and is proportional to the rf voltage on the line. The other is proportional to the rf current flowing in the line. With the swr sensitivity switch pulled "out" in making swr readings, these two voltages are in phase with each other if the load seen by the meter is resistive. With the swr sensitivity switch pushed "in," the phase of the voltage derived from the current is reversed so it is subtracted from the other voltage. The process of nulling the swr indication during initial calibration with a 50 Ohm load is actually the setting of the rf voltage sample exactly equal to the current sample. This is indicated by the null, since the two are exactly out of phase.

Now let's go back to a real fundamental of electricity. The true power being delivered past a point on any line is $EI \cos\phi$, where ϕ is the phase angle between the current I and the voltage E at that point. This is true whether we are dealing with dc, 60 Hz, or rf, regardless of mismatch, line impedance, or anything else. So in order to determine true power under any conditions, we need to measure this quantity.

For such a general case, the voltage derived from the current sample may have any phase relationship from -90

degrees to +90 degrees with the voltage sample, and their relative magnitudes may vary without limit. In the HM-102, meter deflection is proportional to the result of adding these two samples vectorially. The scale is calibrated to give an actual reading proportional to the square of this resultant.

This general case is shown in Fig. 1 for "forward" and "reflected" power. The rf voltage sample is represented by E_E, the voltage from the current sample by E_I. Their vectorial sum is designated as E_F in the forward power case and as E_R in the reflected power case, in which the polarity of E_I is reversed. As Fig. 1 shows, the arithmetic difference between the two scale readings is proportional to EI cos ϕ, which is true power flowing toward the load. We don't need to worry about the quantity "4" in front of EI cos ϕ. With a 50 Ohm resistive load, and with E_E and E_I set equal to each other, the normal calibration of the meter is done so that the correct power is indicated for the quantity $(E_E + E_I)^2$. This exactly equals $4E_EE_I$, so as you can see, the constant "4" is taken into account in the initial calibration, with or without the modifications we are talking about.

Circuit Modifications

From all the foregoing, it is evident that to read reflected power with the HM-102, we need a way to read E_R^2 by reversing E_I when using the power metering positions of the function switch, as we do when reading swr. It turns out that this can be done using the existing swr sensitivity switch to perform this function.

The original HM-102 circuit is shown in grey in Fig. 2 and the circuit after modification is shown in black.

The changes are made as follows:

(1) Remove the 100k resistor R3 from the circuit board and re-connect it in the meter unit from terminal 5 of the sensitivity switch to ground. Also connect a new .001 uF across R3 in this new location. Move .001 uF capacitor C14 to the location previously occupied by R3.

(2) Remove 82k resistor R9 from the circuit board and re-connect it between terminals 3 and 4 of the function switch in the meter unit.

(3) With a sharp knife or razor blade, break the foil connection on the circuit board between terminal 1 of R6 and the nearby end of R4, removing a small segment of foil. Leave enough of the foil coming from R4 to drill a small hole through it. Move the white lead from the interconnecting cable to this new hole instead of point B where it was originally connected.

(4) Move the red lead of the cable from point G on the circuit board to point B where the white lead was originally connected.

(5) In the meter unit, move the red lead of the cable to terminal 5 of the sensitivity switch.

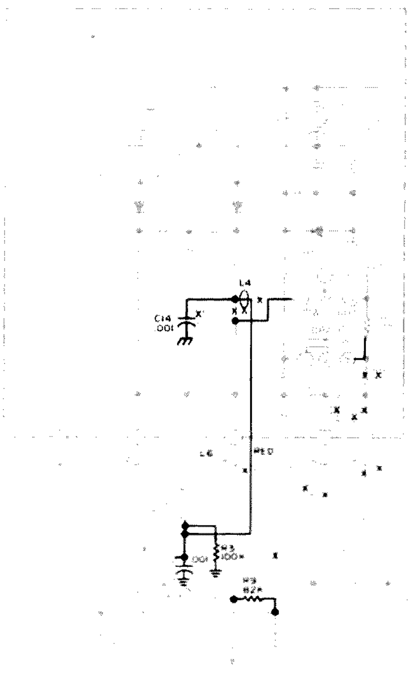


Fig. 2. Notes: 1. All resistors are 1/2 Watt 5% unless otherwise noted. Resistor values are in Ohms (k = 1000). 2. All capacitors less than 1 are in uF; greater than 1 are in pF. 3. Function switch shown in 200 position. 4. Calibrate switch shown in CAL position. 5. Sensitivity switch shown pushed in. 6. This symbol indicates circuit board common. 7. ⏚ This symbol indicates chassis ground. 8. ☐ This symbol indicates an external connection to the circuit board. 9. This symbol indicates a ferrite bead. 10. Overlay indicates circuit modifications.

That's all there is to it. Now the meter will read forward power on either scale with the swr sensitivity switch pulled out, and reflected power with the switch pushed in. True power is the difference between the two readings. The sensitivity control itself has no effect on the power indications when the function switch is set to measure power.

The calibration process and the use of the meter for swr readings are unaffected by these changes. Just be sure the sensitivity switch is pulled "out" for the power calibration! ■

Antenna Magic

--good advice on antenna fundamentals

John Q. Banbury II WB0HAF
Box 554
Breckenridge CO 80424

You have just taken your Novice exam and are eagerly awaiting the arrival of your ticket so you can make that first contact. The piece of wire that is hanging out your window for your receiving antenna will not be the answer for your transmitter's sky wire. So, what are your alternatives? There is a confusing array of antennas available commercially at a variety of prices and hundreds of articles have been written concerning the construction of everything from dipoles to log periodics. I found myself confronted with this situation thirteen years ago and since then have had considerable experience with simple but very effective antennas, and have made thousands of enjoyable contacts both local and DX utilizing these antennas and low power.

Some Basics

First of all, the use of high power is unnecessary. Most Novices cannot wait to buy that kW amplifier so they can have a "big signal." However, if you look at the dB gain in increasing power from one level to another using the formula gain in dB = 10 log P_2/P, you will find that going from 75 Watts to 1000 Watts results in a gain of only about 11 dB. This is less than a two S unit gain at 6 dB per S unit. Granted that this may be significant when chasing rare DX or under adverse conditions, but the majority of your contacts will take place in more favorable situations. So, to communicate effectively, an effective radiating element is imperative.

The Vertical

When I received my license, I purchased a vertical antenna to go along with my fifty Watt Viking Adventurer transmitter. I ground mounted the antenna and drove a six foot ground rod about a foot from the base in accordance with the instructions. In attempting to make my first contact, my worst fears were confirmed. The story that vertical antennas radiated equally poorly in all directions was true. I thought that there must be something to improve the effectiveness of this convenient antenna and there was. Whether you purchase a commercially made vertical or construct your own quarter wave antenna, a good radial/ground system is an absolute necessity whether ground or roof mounted. I found that at least three quarter wave length radials for each band either lying on top of the ground or buried a couple of inches will not only lower the swr considerably, but also vastly improve the radiation effectiveness. Using the formula, quarter wave length =

$$\frac{234}{\text{Freq. MHz}}$$

the radial and antenna length for the Novice bands will be: for 80 meters, 63 feet; 40 meters, 33 feet; 15 meters, 11 feet; and 10 meters, 8 feet.

If a multi-band trap vertical antenna is used, adjust each section for the lowest swr, starting with the highest band. Be sure the ground radial system is connected during the adjustment phase to insure an accurate swr reading. Although it may take time to perform these adjustments, eventually a point will be reached where a low swr will be found on each band. In observing the operation of many verticals, they seem to perform better on the ground with a good radial system than on the roof.

The use of the vertical has proven itself for me over the years and I have worked over one hundred countries running no more than 180 Watts. The small area that this antenna occupies and the relatively low cost puts this antenna at the top of my list for permanently affixed antennas.

The Ubiquitous Dipole

I have been in several situations where it was impractical to install my vertical after initially arriving in an area, and in order to get on the air, I have used a dipole. I am currently using my "portable dipole" with good results on 40 meters. When I put my rig on the air at my Rocky Mountain QTH this past January, there was four

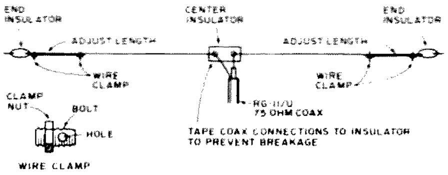

Fig. 1.

feet of snow on the ground. That slight inconvenience prohibited the installation of the vertical. This dipole has been used in various locations with equally good results.

Using the traditional formula for a half wave dipole, total length in feet =

$$\frac{468}{\text{Freq. MHz}}$$

the antenna can be constructed easily and very inexpensively. The higher quality RG11 coax (75 Ohm impedance) is recommended to feed the antenna to increase the transfer efficiency.

If the antenna is to be used as a "portable antenna" as is the one I have constructed, I have devised a simple method of tuning since the characteristics vary according to height above ground and its proximity to obstacles. This method can be used for adjusting the antenna from one band to another or changing the resonant frequency within the band. Using two small wire clamps (available at hardware stores) on each end of the dipole (see Fig. 1), the length of the legs can be varied. Using an swr bridge after setting the length employing the half wave formula, the antenna can be resonated for maximum efficiency. Since the antenna is never cut, the antenna can be lengthened or shortened at any time without having to solder additional lengths of wire to the existing antenna.

I have used this design on 40-10 meters and occasionally add fan elements to the center insulator to allow multi-band operation. I am currently using this antenna on 40 meters and it is only 20 feet above the ground at the highest point and is surrounded by pine trees. I have no trouble working almost everything I hear on 40 SSB and have worked into Europe, South Africa and the Pacific on 40 CW running 180 Watts from Colorado. This antenna was used as a hidden antenna mounted under the eaves of the roof of the bachelor officer quarters when I was in the Air Force and it performed well. Balun feed as well as direct coax coupling has been tried and the difference in performance was negligible. The balun would help reduce TVI if you are in an area where that is a problem.

Conclusion

Ham radio can be just as enjoyable running low power and using simple antennas as in using a beam and a kW. In fact, there is a greater challenge in using simple but efficient equipment. There is always a thrill when working a DX station under these circumstances. Do not let the antenna be the weak link of your station. Take your time in constructing your antenna and insure it is resonant to the frequency you prefer to operate. It does not have to be high in the air if it is well matched. I used a dipole only three feet above the ground in KL7 land for several weeks and had no trouble getting out.

It is not only inexpensive but very interesting to experiment with simple antenna designs. Do not let that rig sit idle for want of an antenna system. See you on the air! ■

Monitor scopes are still regarded as luxury items by many amateurs, even by those operating SSB equipment. This perhaps explains why there are many distorted SSB signals on the air.

See Yourself Talk

- - build a sideband monitor scope

If we want to adjust our transmitters for optimum working conditions, a scope is a must. Being a home brewer, I decided to make my own.

The monitor scope that resulted is suitable for monitoring AM, DSB and SSB, on both receiving and transmitting. There is a choice of either the wave envelope or the trapezoidal pattern. It has a five position bandswitch which covers the following bands:

Receiver:
1. 455 kHz

Transmitter:
2. 160 and 80m
3. 40 and 20m
4. 15 and 10m
5. 6m

A 3BP1 cathode ray tube was used, although a DG 7-5 is to be preferred because it is physically smaller and the internal electrode connections are shorter.

To obtain sufficient brightness, about 800 V EHT is needed. A transformer from an old 6 V vibrator power supply was used. This transformer has a 300 V secondary; the center-tap was not used, and, with a full wave voltage doubler, -840 V EHT was obtained.

The HT needed for the EF91 Miller-transitron sawtooth timebase generator is taken from the -420 V point of the voltage doubler, filtered and reduced to -330 V. The anode side of the EF91 has to be grounded to enable the use of this negative voltage.

This system necessitates the use of a 6.3 V filament winding which should be left floating. The 6 V vibrator primary yielded 8 V, which was reduced to 6 V by means of a 6.8 Ohm 1 W resistor.

Flyback suppression is achieved by taking a negative pulse from the screen of the EF91. This pulse is limited by the OA210 and the resulting flat-topped waveform fed to the grid of the 3BP1 to blank the retrace of the timebase sweep.

Horizontal deflection is controlled by the 1 M linear pot marked "HOR." Vertical deflection is controlled by the 500 pF tuning capacitor. An OA81 germanium diode was used for detection of the horizontal sweep, because there was one in the junk box, but an OA91 would be preferable.

Due to the fact that the horizontal plates D3 and D4 are more voltage-sensitive than the vertical plates D1 and D2, the trapezoidal pattern appears slightly pulled out vertically. In practice this does not matter very much.

The trapezoidal pattern can be reversed, by reversing the polarity of the OA81.

Connecting the Scope to the Receiver and Transmitter

Coaxial cable must be used for these connections.

Receiver

Connect a 5 pF capacitor from the plate of the last i-f tube to the inner conductor of the coax lead.

Transmitter

Mount a 1 turn loop near

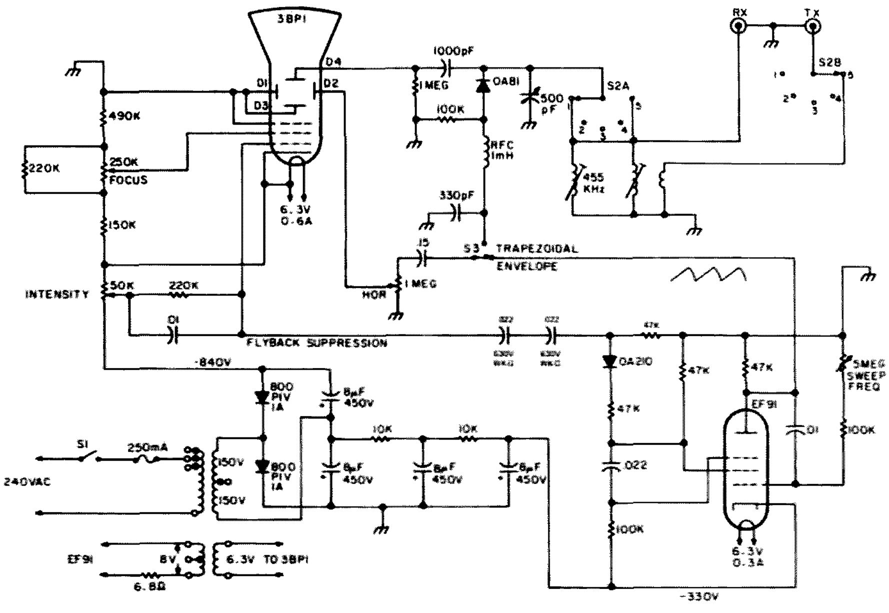

Fig. 1.

Reprinted from *Amateur Radio*, Journal of the Wireless Institute of Australia, October, 1974.

The monitor scope can be seen on top of my allband phasing rig.

the cold end of the PA tank coil and bring the signal out through a piece of coax cable.

Construction Hints

Do not mount the power transformer next to the CR tube. The transformer's magnetic field will influence the electron beam. It is better to mount the transformer behind the CR tube. The layout is not critical. One important point is to mount the 500 pF tuning capacitor with its associated circuitry as close as possible to the 3BP1 base. By keeping the connections between D4 of the 3BP1 and the tuned circuit as short as possible, this monitor scope will work up to 80 MHz.

Preferably, the CR tube should be shielded with a mu-metal shield. I must confess to once making a 144 MHz monitor scope using a DG 7-5 without a shield. It worked OK!

Information on the Coils in the Rf Section

Coil 1 is an i-f transformer with one coil shorted. The other coil is used with the fixed capacitor, which is normally soldered across it, removed.

Coils 2, 3 and 4 are slug-tuned. They are omitted from the circuit diagram for clarity.

Coil 5 is a hairpin loop.

All are link coupled, except the 455 kHz coil.

Note

If a DG 7-5 or some other CR tube is used, the EHT resistance chain should be altered to supply the correct voltages to the CR tube. ■

The Hidden Charger

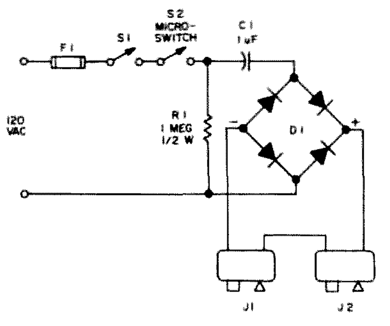
-- simplest charger yet

All right, all you fellow part-time home brewers, this is it. You have all seen the basic charging circuits before, as used in the textbook versions of "the-fundamental-way-to-charge-nicads" type diagrams. Well, this charger is little different except for one or two "convenience and/or safety" features. Just like the title states: This is an inconspicuous charger – plain and simple.

It is said that necessity is the mother of invention and my necessity was to save money! I'd just purchased one of the popular 2 meter hand-held portables and was determined not to shell out the extra twenty bucks or more to buy the accessory charger. After consultation with friends over a few beers, the simple circuit shown in Fig. 1 took shape.

In my particular case it so happened that I was fortunate enough to have an extra set of 10 AA nicads, and so, rather than have the HT sit in a charger for hours on end, I settled on a more convenient solution. I chose to charge one set at home while using the other in the field. Since I operate FM almost exclusively at this time, my "shack" is just about nonexistent. This meant that the charger would have to sit somewhere in the house. With this intent in mind, I conceived the "hide-away" design.

Fig. 1. Charger circuit.



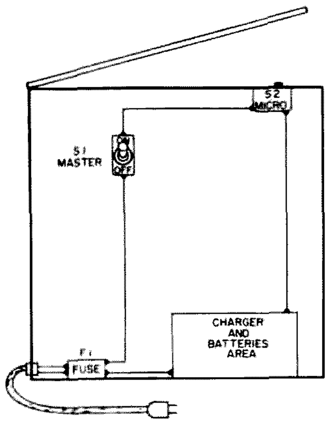


Fig. 2. Block diagram of basic layout.

A quick glance at Fig. 1 will reveal the circuit strategy. The details are rather straightforward. The circuit trickle charges the batteries at 40 milliamps which, in the case of my 450 milliamp hour batteries, was quite acceptable. Some who look at the circuit may balk at the high voltage that appears to be applied to the batteries, but this particular circuit is a variable voltage, constant current charger. Through the loading action the circuit voltage adjusts to the total voltage of the batteries being charged (12 volts in my case).

The charging current, however, is the variable and critical factor. In the case of constant current trickle charging, 450 milliampere hour AA cells should not be charged at greater than 45 mA. Elaborate current regulation could be employed here, but for the sake of simplicity and cost the current regulation in this charger is accomplished through the action of C1. It would seem logical then that C1 should be the highest quality and therefore the most expensive component of the charger. I used a 1 microfarad tubular capacitor that I had in the junk box, but a higher quality capacitor should be used (no electrolytics allowed). The 1 microfarad capacitor regulates to about 40 milliamps of charging current. As a matter of fact, the charging current increases by 4 milliamps for every .1 microfarad of capacitance used (hence 1 microfarad = 40 mA). This variance allows you to choose the right charging current for your need, but remember to stay under your particular charging current limits!

No elaborately filtered dc

is needed for charging, so the full wave rectifier (D1) was chosen to do the job. Just about any cheap little full wave package will do, as long as it is rated high enough. I used a package rated at 200 volts at better than ½ Amp. The resistor R1 is included as a bleeder for C1.

The rest of the circuit is a combination of my love for gadgetry and my previously stated desire for an inconspicious charger. I finally decided to install the entire unit in an old teakwood box that would halfway blend into most rooms.

The actual circuit itself (except for switches) was mounted on a breadboard chip which was placed in a small utility box that sat at the bottom of the teakwood enclosure. The batteries (along with J1 and J2) were simply allowed to lay on the bottom of the enclosure near the utility box itself.

I also didn't want curious souls opening the box while it was in operation and exposing themselves to possible shock. This is where S2 comes into play. S2 is a microswitch, of which I happen to have quite a few. I mounted the microswitch near the top so that closing the lid of the box closed the switch as well. In this configuration the circuit will be deactivated whenever the lid is raised (see Fig. 2). S1 is the master switch (optional), and it occurred to me as I was composing this article that a light bulb or LED indicator could be added. Remember, though, that the circuit voltage will vary from 120 V with no batteries attached to 12 V while charging. The indicator will have to be designed to compensate, of course. For added safety, all exposed wiring should be well covered.

The other minor details concern F1, J1 and J2. F1 is a little bit of extra safety to guard against the results of any accidental shorting. The fuse value is not given here since it will vary for most modifications of the design. Each builder should choose a value to suit his own needs.

J1 and J2 are inexpensive 9 volt battery clips. I used these as a cheap solution to the accidental reverse polarization problem. I decided to load the 10 AA batteries into one 4 cell plastic AA battery holder and another 6 cell AA plastic holder. I purchased the type of holders that sport the mating terminals for the J1 and J2 clips. They are available at just about any local electronics emporium. Note that they are wired in series. This is necessary for each holder set of batteries to get a full charge. It would take a real klutz to try to match the female terminals to female (or male to male), so the possibility of incorrect polarization is reduced somewhat!

A few words on the characteristics of the charger itself would be appropriate here. Do not leave the batteries connected to the charger when the unit is not in operation, since the internal resistance of the charger has a tendency to drain the batteries. Also, this charger is a trickle charger, so about 16 hours of charging time works out rather well. As a matter of fact, the batteries can be left charging longer than 16 hours, but such prolonged charging could develop a "memory" in the cells for a particular level of charge which the batteries will not exceed.

Well, that about wraps it up except to say that this charger article is simply a detail of how I happened to solve a particular problem in a particular way. It is absolutely wide open for experimentation and modification. The urge to modify flows in the blood of most hams, and by the time this article is printed I will have probably already changed the circuit beyond recognition! ■

Compressor IC Expander

- - why go only halfway?

73 Magazine *Staff*

All broadcasting stations employ some device to limit their maximum modulation level — usually a peak limiter. But besides this device, many also employ further speech processing equipment to keep the average modulation percentage as high as possible to achieve maximum effective coverage with the allowed transmitter power level. This means money to the station, and so speech processing equipment can be quite sophisticated and expensive; present solid state units cost about $800. These units perform two main functions: expansion and compression of the audio used to modulate the transmitter. With very low audio input levels, expansion is used to bring up the audio level. When the audio input level reaches a certain point, expansion ceases and then compression takes place as the audio input level increases further.

Almost all amateur type speech processing devices provide a compression function only. This simplifies the circuitry but it has several disadvantages. If one suddenly speaks at a lower than normal level, compression may not take place and the advantage of the speech processing device is lost. If one sets the gain of the compressor so high that compression takes place even with the lowest possible voice level, there will be a great deal of noise in the background and a particularly great noise buildup can develop between speech pauses, depending upon the time constants involved in the circuit that is used.

Building a compressor with an expansion feature also normally would involve complicated circuitry, but a circuit recently appeared (*Electronics*, August 7, 1975) which has greatly simplified the building of such an expander/compressor for amateur usage with any mode of voice modulation. The original circuit was designed for processing touchtone signals. This article describes the circuit and some modifications to it so it can be used for speech processing. The circuit uses only two inexpensive ICs (total cost about $1) and operates from a single supply voltage source of from 7-15 volts. It can, therefore, be battery-powered as a separate unit or housed inside an existing transceiver. In fact, with a little care in construction, it could even be built in the case of most mobile microphones and powered by a miniature 7.5 volt mercury battery every time the PTT button was activated.

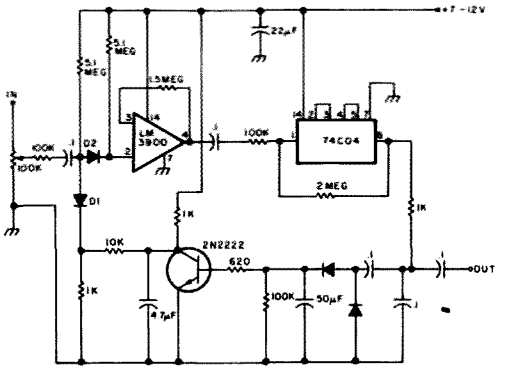

Fig. 1. Complete expander/compressor. Diodes are 1N914s.

The circuit is shown in Fig. 1. The circuit consists of two amplifier stages. The gain of the first stage is variable while the gain of the second stage is fixed. Some output is rectified and used to drive a 2N2222 which in turn varies the gain of the first stage. The neat little trick that is used to allow both an expansion and compression function centers around the biasing of diode D1. The bias on this diode is controlled by the 2N2222 stage. When the output signal of the fixed gain stage is low, the 2N2222 stage is not driven very hard and D1 becomes back-biased. Current flows through R1 into the non-inverting input of the first amplifier stage and its gain increases. As the output of the fixed gain amplifier increases, the 2N2222 is driven harder and D1 becomes more forward-biased. Current through R1 is diverted to ground instead of

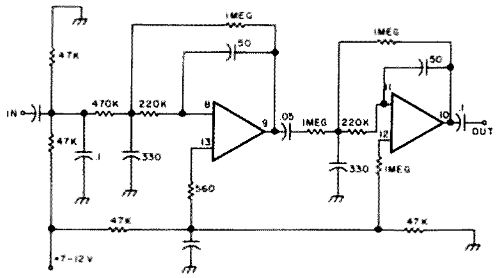

Fig. 2. Two stage low pass audio filters. The op amps are unused sections available in the LM3900 IC of Fig. 1.

to the op amp input and the gain of the input stage is reduced.

The input stage uses a conventional LM3900 op amp. Actually, there are four complete op amps in the IC although only one is used in this application. The input is for a medium to high impedance microphone. Very low impedance microphones will require a preamplifier stage both to raise the output level and to work into the expander/compressor. The 100k potentiometer is used to set the input level so with a normal speech level the unit is in its compression range. This can be checked by a listening test, or better yet, by using a scope to see that the output level of the unit remains constant at the highest setting possible of the input potentiometer. The highest setting possible is that just before the unit is driven so hard that the output clips and becomes distorted.

The second fixed gain amplifier stage actually uses a digital IC – the 74C04 hex inverter. Three of the inverting amplifiers in the IC are wired in series. The other three are unused. Linear operation of the IC is achieved by biasing the inverting amplifiers to the center of their linear range. Part of the output from this is rectified and filtered to drive the 2N2222 stage. The 50 mF capacitors in the base circuit of the 2N2222 and the 4.7 mF capacitor in the collector circuit determine the time constants involved. One may wish to do some experimentation with these values for optimum attack and release times. These values were changed from the original circuit to provide what sounded to be the best results for speech purposes.

A still further refinement can be added to the unit by utilizing the unused op amplifiers in the LM3900 as low pass filter stages. The main advantage to doing this is that in case the main stages are over-driven so they start to clip, the low pass filter stages will filter out some of the harmonics which are generated. The audio signal will still sound rough but at least severe distortion will be avoided.

The circuit of the low pass filter stages is shown in Fig. 2. The time constants are such that rolloff starts around 3500 Hz. The output level is in the order of ½ volt. A potentiometer (100k or higher value) may have to be used to control the output if the level is too high for use with an existing transmitter.

All in all, the circuit provides a worthwhile speech processing advantage with extreme circuit simplicity. With an op amp and three hex inverters left over (even with the low pass filter option added), one could probably add a tone encoder function and/or VOX function also if desired. Quite a lot for $1.00 worth of ICs! ■

Looking West

from page 16

dealing with FCC Chief John B. Johnston's appearance before the southern California amateur radio community. We have spent two columns telling you, thanks to the magic of magnetic tape, what John had to say to us. Now I wish to take a bit of editorial liberty and talk about how I interpreted what he said and what I feel is the best direction for us to travel in working with this fine man.

First, John can only act in our behalf if he knows what we want. This takes a constant flow of information from within the amateur community into his hands and those of his staff. Remember, though, that if you intend to write John because you see something that might affect the continued viability of amateur radio, it is not enough to sit and write criticism. Criticism brings with it a rather specific obligation to provide an alternative, another direction to follow or other specific ideas to back your point of view. Anyone can easily say "I don't like that" or "I don't like that because we can't do it" or even "You're crazy; go soak your head." The aforementioned takes virtually no intelligence and only the most gut level animal instinct. However, to sit down and analyze a given piece of pending legislation as an adult, to view it not only from a personal and thereby somewhat selfish standpoint, to, far more importantly, look at how any given proposal will ultimately affect all amateurs and amateur radio itself, and from this to formulate a reply that is constructive, is the obligation of anyone who decides to offer any form of official comment.

This, then, means that before you sit down to write it might be wise to discuss your views with others to see how they feel and if they can offer any input by way of comment or suggestion. By doing this, you then not only represent your views, but perhaps a cross section of your area's total amateur population. One of the best places I know to hold such discussions and thereby formulate replies to dockets issued by the Amateur and Citizens Division is at a local radio club. In fact, when an issue arises that calls for comment, one of the best ways that I can think of to get some attention for your point of view is to have a radio club behind you. One of the things that John is looking for is "commentary that is well prepared and representative of the majority of the amateurs of a given area, organized commentary of the type that not only offers either backing or criticism, but alternatives as well."

I tend to look at the radio club as the hometown grass roots political organization. It is one of the few forums we have other than talking on the air, and as such has a lot to offer. If you do not now or never have belonged to a radio club, but are getting the bug to take a more active role in helping plot the future course of the amateur radio community, that's really where it all starts.

In my book we have one heck of a good guy representing us to the Commission in FCC Chief John Johnston, but to be totally effective he needs to hear from us and get our ideas once in a while. While I might not agree with everything that he places before us in docket form, at least I know that he will take the time to read my comments and yours and base any final legislation on our needs, doing so to the best of his ability. I can ask little more. I can, though, wish him continued success in what must be one tough job.

Awards that amateurs can "win" are described by Mary and Ed Kellitz WA6EJP. ATV at left was also described that evening by an ATV expert.

Measure Your Wasted Power

- - how much are you losing in your feedline?

Transmission line attenuation is one of those items which most amateurs, especially newcomers, realize is important but rarely do anything about. One reason for this feeling probably has to do with the fact that transmission line attenuations, when quoted in dB, don't seem very meaningful. That is, a transmission line attenuation of 2 or perhaps even 3 dB seems to have a less disturbing effect upon an operator than learning that the output of his linear amplifier has fallen from 1,000 W to either 500 or 620 W. Yet, the transmission line attenuations quoted would have the same effect as far as the *radiated* signal is concerned. Also, many operators go through a lot of work to construct new linear amplifiers in order to raise their power level by a factor of only 2 or 3 times. Yet, on the higher frequency bands where fairly long transmission lines are used, the same increase in effective *radiated* power can be nearly achieved by replacing a long run of RG58/U line with RG8/U line!

Table 1 shows the attenuation characteristics of the three most common types of coaxial transmission lines on the various amateur bands. These attenuations are for brand-new line without connectors. Even so, the losses start to become significant on the higher frequency bands. When one considers line that has become aged, and when connectors and other "lossy" devices are used in a transmission line, the total losses can rapidly add up to significant values even on the lower frequency bands. The buildup of such losses can take place over a period of time and so gradually that no apparent deterioration in either transmitter or receiver performance is noted. The buildup of such losses will not be indicated by the tuning meters on the transmitter, nor on the swr meter readings as long as the antenna remains correctly impedance matched to the transmission line.

Most amateurs realize to some degree the desirability of keeping line attenuation as low as possible, but rarely do anything more about it other than initially carefully installing line believed to be fresh. The reason why line attenuation is not periodically checked as it should be is the difficulty involved in making such measurements by conventional methods. Certainly, few amateurs would want to measure the power input to a line, dummy load the far end of the line, measure the rf voltage across the dummy load, calculate the power output, and then finally find the line attenuation. Various errors can be involved in making such measurements, and good test equipment is necessary for accurate results. Some years ago a method for line attenuation measurement was suggested using the technique of shorting the far end of the line to create a complete reflection of the incident power traveling down the line. By swr measurement at the transmitter, the line attenuation could be determined. The basic concept of the measurement technique was good, but there were several disadvantages for practical usage.

The measurement technique described in this article refines the technique by the use of a carefully chosen load to create an artificial swr. The result is a measurement technique that is particularly sensitive to even small changes in line attenuation and a method that needs only a regular swr meter to implement. Even the swr meters built into some equipment which are calibrated only up to 3:1 swr are satisfactory.

Basic Theory

One should be familiar with the theory behind the swr method of line attenuation measurement. The method is based on the fact

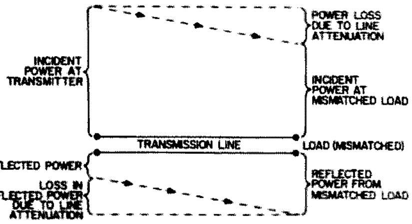

Fig. 1. The effect of line attenuation as explained in the text produces different swr readings at the transmitter and load (antenna) ends of the line. Example: P(incident) = 100 W, line attenuation = 3 dB, load swr = 5:1. Incident power at load = 100 x ½ = 50 W. Reflected power at load = 50 x .445 = 22.25 W. Reflected power at transmitter = 22.25 x ½ = 11.12 W. Power ratio at transmitter = 11.12/100 = .1112 = 11% of incident. Swr at transmitter (from Fig. 1) = 2:1.

Nominal Attenuation dB, Per 100 Feet

Band	RG58	RG8	RG59
160	.6	.2	.5
80	.82	.3	.65
40	1.3	.45	.9
20	2	.5	1.4
15	2.5	.62	1.6
10	3	.8	1.9
6	4.1	1.4	2.5
2	7.8	2.5	4.0

Table 1. Attenuation of various coaxial transmission lines on 160-2 meters. These losses are for brand-new cable and do not include additional losses due to connectors, relays, filters, etc., used in the transmission line.

that the swr values for any value of swr other than 1:1 will not read the same at both ends of a transmission line — if the line has *any* attenuation whatsoever. This concept is illustrated in Fig. 1. The ratios of the incident and reflected power at any point along the transmission line are related to the swr that would be read at that point. Note that at the transmitter end of the line, the reflected power is only a small portion of the incident power while at the load (deliberately mismatched to create a specific swr), the reflected power is almost as great as the incident power.

This change in the ratio between the incident power and reflected power at the transmitter end of the line is directly related to the total attenuation of the line. The effect is such that the presence of even small amounts of attenuation can be readily determined. The sample calculation shown in Fig. 1 should be followed through once carefully in order to understand the principle involved. Table 2 is a simple listing of how much of the incident power is reflected at a *load* for a given swr at the *load* terminals. It must be used to understand the example shown in Fig. 1. The example itself shows what the swr reading would be at the transmitter end of a transmission line if the line had an attenuation of 3 dB at the operating frequency used, and if the load were mismatched to the transmission line such that a 5:1 swr existed at the *load*. As shown, the swr reading at the transmitter would read 2:1 and not 5:1 due to the line attenuation.

In the manner shown, one could calculate what the swr readings would be at the transmitter for any given *load* swr and various line attenuations. A listing of the results of such calculations for load swrs of 5:1 and 3:1 and various line attenuations is shown in Table 3. Note

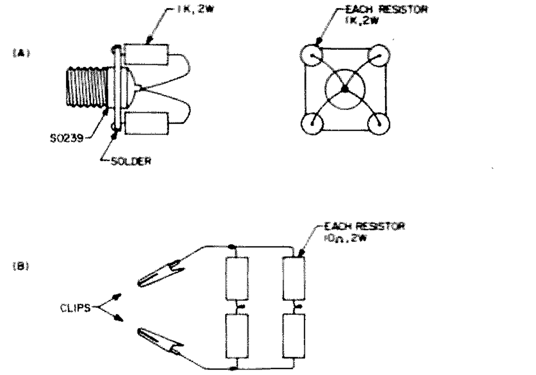

Fig. 2. Two resistor assemblies that may be used at the antenna end of a transmission line to create a given load swr for test purposes. The usage of each assembly is explained in the text.

particularly how sensitive the swr reading at the transmitter is to even small line attenuation values. For example, for a 5:1 load swr, the swr reading at the transmitter would be 5:1 if the transmission line used had no attenuation. However, even a line loss of only ½ dB will cause the swr reading at the transmitter to be 3.9:1 instead of 5:1. The load swrs shown in Table 3 were chosen to be listed because, in practice, they are usually the most handy to use. They permit good indication of the range of line attenuations likely to be encountered in most installations, and the range of swr readings produced at the transmitter is within the range where most swr meters (including those built into transceivers, linears, etc.) can be clearly read.

Using The Technique

Using the technique just described to make actual line attenuation measurements is not at all difficult as long as a few precautions are observed. Any swr meter can be used, either a separate unit or one built into a piece of equipment, as long as swr readings of up to 3:1 can be calibrated. One must be *sure* of the calibration of the swr meter, or else the measurements made will be meaningless. The instruction book for most swr meters describes a calibration procedure. In any case, one can check the calibration by using 2 W carbon composition resistors directly at the swr meter, choosing the resistor values to simulate different swrs. For example, an swr meter meant for use in 52 Ohm transmission line can be checked for its 2:1 swr reading by using a 104 Ohm resistor (nominal 100 Ohm unit), for its 3:1 swr reading by using a 156 Ohm resistor (nominal 150 Ohm unit), etc. Usually from a batch of 10% tolerance resistors, one can find the necessary resistor values. If this cannot be done, or if a good ohmmeter is not available, 5% tolerance resistors in stock values can be used for calibration. In any case, noninductive-type resistors should be used and the swr meter checked over the range of frequencies to be used.

Once one is confident that the swr meter calibration is correct, a resistor unit must be constructed to simulate either a 3:1 or 5:1 swr at the antenna end of the transmission line to be tested. One suggested method of construction is shown in Fig. 2(a). A grouping of four 2 W composition resistors is soldered directly on an SO-239 coaxial fitting for use in a situation where the transmission line used employs a standard PL-259 connector at its antenna end. The resistors are wired in parallel and chosen in the example shown to provide a 5:1 swr for a 52 Ohm transmission line system. The resistor unit can be checked that it provides the correct swr by connecting it directly to the antenna side of a calibrated swr meter. Usually if the resistors were carefully chosen beforehand using an ohmmeter, there will be no difficulty. Again, the resistor unit should be checked on all frequencies where it will be used to check line attenuation.

After everything has been calibrated, the far end of the transmission line is disconnected from the antenna and connected to the resistor unit. A few Watts of transmitter power are used so a proper "set" reading can be obtained on the swr meter at

swr	Incident Power Reflected (%)	swr	Incident Power Reflected (%)
10	67	2.5	18.3
9	64	2.0	11
8	60.5	1.9	9.6
7	56	1.8	8.2
6	51	1.7	6.7
5.5	48	1.6	5.3
5	44.5	1.5	4.0
4.5	40.5	1.4	2.8
4	36	1.3	1.8
3.5	31	1.2	.8
3	25	1.1	.2

Table 2. For a given swr at a load, the listing shows the percentage of incident power which the load does not accept and reflects back along a transmission line.

For 5:1 Load swr

Cable Attenuation, dB	swr at Transmitter
.5	3.9:1
1	3.3:1
2	2.45:1
3	2.0:1
4	1.7:1
5	1.5:1
10	1.15:1

For 3:1 Load swr

Cable Attenuation, dB	swr at Transmitter
.5	2.6:1
1	2.3:1
2	1.9:1
3	1.7:1
4	1.5:1

Table 3. Transmitter swr readings as a function of line attenuation for load swrs of 5:1 and 3:1.

the transmitter when it reads forward power. The meter is then switched to reflected power, the swr read, and the total transmission line attenuation determined using Table 3.

The method can actually be used in many installations without even disconnecting the transmission line from the antenna. If one knows that the antenna has been adjusted to provide a 1:1 match to the transmission line at the transmission line/antenna interface, it is only necessary to parallel the antenna terminals with additional loading to create a 3:1 or 5:1 swr. A grouping of resistors made up as shown in Fig. 2(b) might be used for this purpose. In this case, resistor values must be used which are lower in value than the line impedance, since they are placed in parallel with the antenna terminal impedance. As shown, four nominal value 10 Ohm resistors are grouped together and chosen to produce an overall resistance of 13 Ohms, which in parallel with a 52 Ohm antenna will provide an effective termination of 10.4 Ohms for a 5:1 swr. One resistor could possibly be used if the swr meter used at the transmitter were sensitive enough and only a few Watts of output power were necessary. The "clip-on" resistor unit can be checked, of course, by directly coupling it to the swr meter where, by itself, it should provide a 4:1 swr reading.

Summary

Many amateurs who check their transmission line attenuation for the first time are shocked at the values they discover, particularly on the higher frequency bands. One should realize that besides the transmission line itself, one will also be reading the attenuation introduced by the various relays, filters, switches, etc., used in the transmission line in more elaborate station setups. No matter what the attenuation is due to, however, it of course reduces the radiated power and the sensitivity of the receiving system (assuming the same antenna is used for receiving).

A periodic check of line attenuation will quickly reveal any developing problems. In installations where the antenna end of the transmission line is particularly difficult to get to, one might even consider installing a relay at the antenna so a test resistor unit can be selected to check the line condition whenever desired. Before the installation of any transmission line, its attenuation should be checked so one will then have some basis against which to evaluate later attenuation measurements made when the line is installed. ■

Tragedy On Mt. Wilson

Late this evening it was dramatically proven that preparedness and training in the art of locating a hidden transmitter can pay off. The Mt. Wilson Repeater Association has been holding bi-weekly T-Hunts using the input channel to the WR6ABE repeater and doing so while the repeater is in full operation. I cannot think of any more adverse conditions under which to try and T-Hunt anything.

About 5:45 on the evening of Saturday, September 4, a rather raucous noise appeared on the input of WR6ABE and stayed there. Later in the same evening a rather foul-mouthed character appeared on the system claiming responsibility for this sickening act against the Southern California amateur community.

A check of the input by various stations around the city gave an approximate location for Mr. Foul Mouth, but didn't reveal the source of the raucous buzzsaw noise. Not being able to hear the interference from the lowlands even on the rather super-sensitive L-Per DF receivers connected to base station antennas, the T-Hunt crew decided to play a hunch and go check the area of the site itself.

By about 3 am, the T-Hunters were sure that their hunch was correct, but the darkness and rather rugged terrain made any further attempt to get an exact location a dangerous job. Around 4 am the T-Hunters came down off Mt. Wilson and arranged to meet later in the day.

Later that afternoon, September 5, again the T-Hunters headed back up Angeles Crest Highway to the area of the WR6ABE site and brought with them not only DF equipment but metal locaters as well. It took another few hours, but the winner and champion of this T-Hunt turned out to be the ham who located the jamming device about a quarter of a mile from the repeater.

Bill Pasternak WA6ITF
Panorama City CA

By the time you read this, WR6ABE will be silent. Owner Burt Weiner K6OQK decided in late October to shut his Mt. Wilson machine down for 60 days, rather than put up with the jamming, obscenity and varied shenanigans of a handful of users. Some users reportedly have threatened to sue on grounds it and all repeaters are not the property of the owner but rather, by virtue of the service they perform, have become a public utility. One user is trying to drum up support for a separate suit on the grounds he had to buy crystals to use the repeater and the shutdown would make them useless. He claims fraud and is demanding that the system stay on the air to protect his investment (see Briefs). — Ed.

EDITORIAL BY WAYNE GREEN

ARRL REPORT

Well, here comes Wayne Green bad-mouthing the League again . . . right? Right. This time it has to do with a letter from *QST* (which many of our readers have been forwarding) which asks why authors are not writing for *QST* any more.

I think I can answer their letter . . . perhaps better than many of the readers who got it. I'll try to do it without being sarcastic or nasty, which (you know) has to be a major effort for me.

The ARRL has set itself up as the representative of amateur radio. While many of us realize that this is largely fiction, the image that ARRL must project to maintain this fiction is one of service and infallibility. This image has been getting pretty tacky of late, particularly with respect to any correlation between promises made by League officials and performance in the WARC situation. The decision by *QST* to stonewall the situation has disillusioned tens of thousands of amateurs and has, in a large part, I believe, been responsible for the loss of interest on the part of both the subscribers and writers in the magazine.

I think all of us would feel a lot different about *QST* if we knew that the ARRL was fielding teams of ambassadors to the Third World countries to sell the concept of amateur radio so that we would have some votes to back us up at Geneva. There is still time for this — but *nothing* is happening!

The recent FCC revelation that much of what ARRL had been telling us in *QST* about possible new ham bands was just hot air hasn't helped the ARRL image at all. We don't like being lied to.

The Board of Directors of the ARRL Foundation had the right idea . . . they wanted to get the League to stop talking and *do* something about the ITU frequency conference. Their efforts to get money from the League for this purpose failed, so then they went about setting up a fund drive to get money so the Foundation could act. When the ARRL refused to even let them do that, the board resigned in protest . . . en masse. Can you even think for a moment that hams such as Bill Eitel and Pete Hoover don't know how serious the ITU situation is and how desperate the need for immediate action is?

When amateurs regain confidence in the League, I think we'll find plenty of authors submitting articles. Authors want to be proud of where they are published, not ashamed. As soon as amateurs feel the League is being honest with them and doing the job they claim they are doing, there will be articles and subscribers.

The recent election of ARRL directors was a particularly sorry spectacle. One director was replaced by a new man . . . all the rest either ran unopposed or else won their elections . . . every last one of them. This indicates to me a massive apathy on the part of ARRL members. While the directors have very little to do with running the League, they are the only ones who can make any major changes in the people who are running the League and who are letting amateur radio, as we know it, go down the tubes.

I'll tell you this . . . if ARRL convention program committee chairmen have any sense, they won't ask *me* to come and talk. I have no good news as far as WARC and the ITU are concerned. I do have a lot of inside information, but there is none that you really want to hear. The League knows this just as well as I do, but I know they are far more interested in spending $800,000 on a new wing for the HQ building than trying to protect our bands. I just happen to think that the rainy day the ARRL saved up that $1 million they have in the bank for is here.

Hmmm, I didn't realize I was so steamed up over that. Sorry if I came on stronger than I intended.

Congratulations to Don Miller W9NTP for winning the Central Division directorship of ARRL. Don is one of the authors of the SSTV book . . . not the long-forgotten DXer. Congratulations, too, to Gay Milius W4UG for winning the vice director's spot in the Roanoke division. With those two exceptions, every ARRL officer held tight, so we're probably headed into two more years of inaction.

If a director or vice director comes to your club for a visit, put him on the spot and ask him to tell you what happened with the ARRL Foundation . . . he knows full well about it, if he'll level with you. Ask him about the money that has been spent from the $100,000 fund to protect amateur radio . . . he also knows exactly how that has been spent and why not one word of it has ever been printed in *QST* or even leaked in the ARRL annual report. Start asking questions, so you can get to know your League and perhaps push for some serious reforms.

FLY THE FLAG

It really got home to me a few years ago when I began traveling. Until I had had a chance to visit other countries and talk with the amateurs there in depth, I really hadn't understood some of the profound differences between the opportunities we have here in the US and the problems people face in other countries . . . just about *all* other countries.

While I am not now much on owning things, back in the late 50's, while I was editor of another magazine . . . possibly one which you are unfamiliar with . . . I was single and had quite a few hobbies up and running. There was my Arabian horse which I spent several years riding and training . . . a Chris Craft express cruiser for water skiing and boating trips . . . a two-place seaplane . . . and not one, but *two* Porsches. On the hamming front, I had a 75m kilowatt, an all band kilowatt, and a 2m kilowatt . . . all homemade . . . an amazing amount of RTTY equipment . . . and I was putting out a monthly RTTY bulletin to about 2000 subscribers. As I said, I was single.

When I visited other countries, I would occasionally find someone wealthy enough to own a plane . . . or a boat . . . or a sports car. But it took enormous wealth to be able to afford all these things at once . . . it was just totally beyond possibility for all but a very few. Since I was not making a lot of money and I was able to afford all those nice toys, it emphasized the difference in opportunity between countries. Not many of us are energetic enough to try and do all those things at once, but if we want to, it isn't that difficult to do. It is *our* choice.

Though we have a lot of problems with our courts, with our government, with big business and the other power structures, in all we have a lot more opportunity here than our counterparts have in other countries . . . and I've visited almost a hundred of them now.

Perhaps I'm off base, but to me, despite the harassment I've had from our courts, government, and big business . . . and they've each done fantastic jobs on me . . . I think the United States is great and I am proud of the good things that people are doing. Just think of it . . . despite two hundred years of the worst things that the courts, government, and business could do, the spirit of the nation has come through and triumphed. I say

BE MY GUEST

visiting views from around the globe

The Lady in the Harbor

It is simple to write about the amateur radio happening on Liberty Island NY, on the four day Thanksgiving holiday, 25 to 28 November 1976. How did it happen? It was the brainstorm of "Doc" Lew Levitt WB2NDI, Kings County Radio Club, Brooklyn NY. "Wouldn't it be nice if amateur radio could be treated to an event similar to Op-Sail '76 to celebrate the Bicentennial?" Getting the idea into reality took months of concerted effort by lots of people. The actual event, the four days of glorious activity, was the climax of some anxious times. Doc brought his idea to the Hudson Amateur Radio Council (HARC), where he proposed that it take on the big job of organizing, coordinating the preliminaries, and then operating WL2USA. What follows will describe the nitty-gritty of getting the idea into reality – the many hours of planning, letter writing, and telephone calling. Most of the work was done in the morning before work, and in the evening after work. There were some unavoidable interruptions during regular working hours, but these were kept to a minimum.

The value of this narrative lies in showing that anyone who takes on anything worthwhile to do, for the first or for the millionth time, will find that there is going to be lots of lost motion, lots of frustration. If it comes off, in spite of all obstacles, you will honestly come by a sense of gratification and achievement that no one can take away from you. This will give you confidence to go on to even greater and higher goals. When Doc Levitt came to HARC and made his proposal, it was very clear that it might be a tough assignment. Then why did I take it on? It was complicated enough to be interesting.

Problem Number One: In order to get a permit from the U.S. Department of Interior (National Park Service) to put on a special event on Liberty Island NY near the Statue of Liberty, an applicant must agree to observe the regulations that are in force. Most are simple housekeeping ones, others regulate the limits of the activities, and others say no camping, no fires. We set out to find a way to get around the regulation about camping and structures. The solution was obvious – so we thought. Thus very early in the game, we became our own worst enemy. We learned a lot in a short time about negotiations with U.S. Government agencies. It was bad enough dealing with the FCC for the special call. Doc Levitt is one of the most persistent persons around, and, thanks to that, the special call was issued, but not until after months of waiting, griping, calling (but mostly waiting and waiting some more). We decided to "go to higher authority" for exemptions to permit us to erect structures. After all, an antenna *is* a structure! The whole project nearly folded then and there. For future reference, anyone dealing with the U.S. National Park Service should remember this: The U.S. Park Service rigidly adheres to the "captain of the ship" policy. It is an enviable policy, in that it maintains authority and responsibility in the field. The best qualified to make a decision is on the scene, and the decision is made on the spot. It has proven to be very effective. It was our tactical error to try to circumvent the authority of the Superintendent of Liberty Island. Once we accepted the stringent restrictions, we found that he was also prepared to go out of his way to extend the help he was authorized to give. We became very good friends. Without the Service's kindness and help, we would not have been able to take our gear, set up for four days, and operate at all. From the very first day (during our site visit), they gave excellent advice and suggestions on how to prepare for the worst. They even made storage facilities available. We had access to the maintenance shed for inclement weather and contingencies, where we could set up at least the 2 meter, 20 meter, and OSCAR station. To Mr. Luis Curbelo-Garcia and Mr. Dean Garrett, many thanks. Moral: Find out very early. If you can't fight 'em, join 'em . . .

So a month before the event, we had the site. It was also three weeks before the HARC Convention at Great Gorge, and the convention committee had more pressing matters than worrying about li'l ole WL2USA. We got individual help, but in general we were on our own.

Most of you who went to the HARC Convention saw how we tackled Problem Number Two: How do you motivate people to go out into the cold, get on a subway, buck the crowds (while lugging a rig), ride to the tip of Manhattan, dress for the rigors of wind and spray, and stay for at least four hours? It wasn't easy. You set out to get as much help as you can, from anyone, and from anywhere. Keep in mind that the impetus has to come from you. It can get lonely. How persuasive was the blurb in the Convention program book? It was a flop. Two live takers came from it: Stu K2RPZ and Harry WB2FZE. They said they would come, because they knew what it might be like, but since they were well-weathered fishermen, they could hack it, no matter what! I wish there had been fifty more like them! Then I went to the DX session moderator to sneak time before the regular sessions to drum up more takers. No luck from that tack. The weekend before the event, we had to go the Island to conduct field tests, and literally test the water. Doc Levitt met us with his two meter FM rig, and we took our SBE 34. The purpose of going was to find out what loose ends were left, what had to be revised, and what it was going to be like. It was miserable, damp, and windy, and my rig didn't work. We were off to an inauspicious start, indeed . . . We also had to find out where to plug in the extension cords, where to find the johns, how to set up a mast and guy it according to regulations and for safety, where to get a snack, and where to thaw out. I was chilled to the bone, and three days later the ache was still there.

From left: Wally WA2NVG, Arnold WA2CID, Carlos WA2AUV, Allyn WB2ZKZ.

Would the four day stint do me in?

Father Vic W2IJC called long distance from Rensselaer NY for information and details about WL2USA. We made a sked for 3850 kHz. With John W2BPU in Teaneck, and Don WB2VJC on the side in Rensselaer, Father Vic said he would come. Things might be looking up. On the day before, the roster included Doc WB2NDI, Allyn WB2ZKZ, Larry WB2TXL, Paul WB2CNF and Ed WB2UDD. So on Thanksgiving morning, we loaded up the VW Rabbit, checked the ropes on the roof carrier to see if the antenna masting was secure, gassed up, and went down to the back of Midas Muffler to find old muffler clamps for the antennas. Then it was down the Jersey Turnpike for the Holland Tunnel and the Battery.

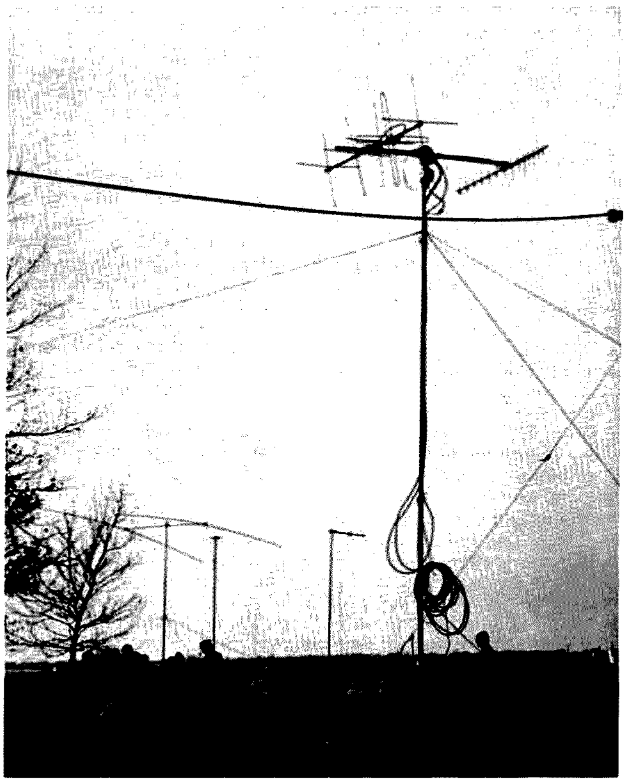
Liberty Two, the U.S. National Park Service bumboat, pulled up to the dock. We were waved on by the sentry to the Coast Guard parking lot adjacent to the Marine Inspection Office at the Battery. This was another example of how far the Park Service went to extend their help. There is very little parking in the vicinity of South Ferry. What there is, naturally, is expensive. More importantly, we needed access to the dock to offload our masting and gear. This was a very generous act. More on parking later.

The skipper of *Liberty Two*, I found, was a signalman on the *USS Utah* at Pearl Harbor. He and I must have been a few hundred feet from each other during the war years. My activities as a civilian radio operator on the tugs and dredges took me into the same areas of the Navy Yard. It took over thirty years and several thousand miles to find out about each other. This brings up another point: You can expect to discover new things and meet lots of nice people when you set out to do something worthwhile. I am sure the skipper would have been just as helpful otherwise, but it was still awfully nice to be aboard a tug again, feel the vibrations of the engines underfoot and the spray on my face again! Then, to take me all the way back to those days, he let me use the FM rig aboard *Liberty Two* to inform the acting superintendent of Liberty Island when we got underway!

As operations go, most of us have been on field days much more elaborate than WL2USA. First of all, we were limited by the rigs that could be brought conveniently. *Liberty Two* had very limited space and storage. At no time were we in full operation simultaneously on 20, 40, and 80 meters. We set up the best we could with what was brought in rigs and in antennas, commencing at 8:00 am, and we made our first contact on 20 meters at 12:15 pm with Harvey WAØOBY in Missouri. We made our two meter contact a little earlier at 11:25 am, through WB2UDD's five Watt FM rig, with Steve WA2OHF. It was a cold, overcast day, and even at the slowest exposure the colored film did not give very good pictures. Ernie WA2HLY did the best he could with his camera. He loaned them to me for photoreproduction to black and white 8x10's. As you can see, we set up near the flagpole opposite Ellis Island and the Battery, with the 20 meter beam set into a flag stanchion and then guyed ten feet above the ground (to avoid scalping anyone). We used the armstrong rotator if we needed to. Considering everything, the two element beam did very well into Europe and nearly got us WAS. We missed by about six states, and Father Vic, bless him, got us Nebraska! Our 80 meter antenna was a home brew helically-wound vertical. Allyn WB2ZKZ and myself made it in a couple hours in our backyard QTH.

The showpiece of WL2USA was the OSCAR station that Art W4ART brought up from Arlington VA. Art was my other live catch from the HARC Convention. On the basis of the showstopping OSCAR demonstration at Great George, Art decided to come up to New Jersey and spend Thanksgiving with his family. He gave me a lot to be thankful for, too! With Art came Murphy, in spades. We set up the OSCAR station on Thursday, but missed all the passes for that day. It would have been nice, but it was asking too much to be able to set up in an hour to get the morning pass. Art had run out of gas and barely made it to the parking lot, and on a Thursday holiday afternoon we would not have found a gas station open for business. So we left his van in the lot overnight.

The next day, Friday after Thanksgiving, is a regular working day for the U.S. Coast Guard. Shortly before that, Art had found a badly damaged 432 MHz transceiver. It was clobbered – it hit so hard that the impact had sheared the mike plug plastic insert and bent the gain control shaft. I had personally put the station away. When I closed the storage shed door, I must have pushed it off the top of the pile onto the floor. As luck would have it, he had borrowed it! I thought Art would pack up and go back to Virginia . . . Not two minutes later, while I was still breathing hard, Dean Garrett came over with crisis number two: "You'd better call Chief Dick pronto. He is good and mad, since he's just been chewed out by the E-X-O for allowing an unauthorized vehicle of another governmental agency to park with tags marked W4ART." I think that's what may have saved me. Art had left his FCC identification in the car, too, and I couldn't get up enough nerve to tell the Chief that W4ART was not a government license plate. The other reason that I might have been saved was that there were other things going on. It must have been close to noon when I called back to apologize. The Friday after Thanksgiving had gone well, and the Chief allowed us to park there for the rest of the day – as well as Saturday and Sunday! He could have scuttled WL2USA and me too if he had barred us from parking. When it rains, it pours . . . but we were actually spared on that score. The weather for the four days was nearly springlike. So the blurb had done too good a job, and scared everyone away. We made 33 contacts with OSCAR on orbit numbers 9295A, 9307B, 9308B, 9320A. Amateur radio, public relations, the United Nations, the UN Meditation Group, the Bicentennial and the Statue of Liberty achieved Unity with the Universe in the middle of orbit 9307B at 1459 UTC. Art W4ART was explaining the OSCAR station to a member of the UN public information staff. Bernard Curchack from the UN Meditation Group had also come to Liberty Island to give thanks and pay homage to the Bicentennial. Unfortunately, the park authorities, in deference to WL2USA, refused permission to them. So it seemed the gracious thing to do to let Bernie read his poem of praise (panegyric) on OSCAR! It was, for all observers, a very emotional event. This was a very unique event indeed! While all of WL2USA was a noble undertaking, this particular event was transcendent and mystical. It made all the effort worthwhile. So on Sunday, when Father Vic came aboard, he put the topping on the affair by representing the clergy and our freedom of belief and conviction.



WL2USA antenna farm (Ellis Island in background).

The other circumstance that made WL2USA memorable was the cultural and ethnic mix. We had the WASPs, Jews, Afros, Hispanics, and people of Asiatic ethnic origins. All there to honor America by means of amateur radio. What other time would you expect two radio amateurs, Allyn WB2ZKZ and Carlos WA2AUV, to limber up after a stint at the mike with the ancient Chinese t'ai-chi? No way, no how – gung ho! Allyn is one half Chinese, and Carlos, Hispanic. They were all very decent fellows, full of enthusiasm, very competent. They will go fair and far. The other visitor from the Quisqueya Amateur Radio Club, Bronx NY, was Arnold WA2CID. Of all the calls for any Hispanic to get! El Cid of Charlton Heston fame is the national hero of Spain and the cultural superman of the Hispanic culture, and apparently it had not occurred to Arnold that this was the case. He was most delighted to be told this by me. We made as many DX QSOs as the number of operators (about three dozen), including Pete WB8NAS/1 and Sally WB8NOK/1, Luis HI8LMK/W2, Irene WA2LWG. The other radio club that sent operators was from St. Peter's Prep (K2OQJ) – Bob WA2DMF, Taras WB2ERD, Walter WA2ZNW. Paul WB2ZNF, Englewood NJ, was our statistician. According to him, WL2USA made a total of 1142 QSOs. Two meter FM accounted for 560, and the low band for 549. Limitations of time and coverage kept others from a QSO with us. If you feel you deserve a QSL for your effort, send a QSL card, tell us the time you tried, what you heard, and whom you heard, and we will send off the QSL to you as a souvenir. All who contacted us and were confirmed will, of course, receive the commemorative WL2USA QSL. Designing the QSL is a story in itself.

Whenever you set out to make a QSL card, you are making an esthetic statement. For me, it requires a lot of introspection and sober thought. In this case, we had to epitomize the spirit of the project. Some of the people I asked suggested we do it whimsically. Why not the Statue of Liberty holding a tribander beam? No – too frivolous. I recall the anguished responses when someone suggested a red, white and blue sash for the

Lady in the Harbor. Once committed to a matter-of-fact, straightforward treatment, the matter becomes somewhat easier. When Larry WA2FSY and Roz WA2EMC heard about the idea, Larry gave me a photoreproduction of a woodcut of the Statue. Then, to be authentic, should we include the Emma Lazarus quotation about the tired, poor and huddled masses? So a call was made to Dean Garrett and by return mail came a picture of the tablet in memory of Emma Lazarus. It is in Gothic sans serif type, cast in brass and located in a place of honor. An entire QSL card in Gothic sans serif just didn't seem to look good, nor did all italics or Roman. What to say, and how to say it? My tentative designs were shown to my artist friends, who were very helpful. Finally I went to the Suburbanite in Englewood to see Jules and Richard Jacobson. We went to the photo font machine and chose italics and Roman. The next day the Audio-Visual Department made me a 3¼ x 5½ inch negative for the QSL card and a 8½ x 11 transparency for transvue projection. Those who went to the DX sessions at the HARC Convention saw that result.

Again, there is more than meets the eye. In order to legitimately display the NYC Bicentennial logos, we had to get permission from Dr. R.L. Gaudreau, Executive Director of the NYC Bicentennial Corporation, the same outfit that brought you Op-Sail '76. Then, to get permission for the American Revolution Bicentennial logos, we had to write to the NY State Bicentennial Commission in Albany. Then, and only then, with the endorsement and approval of the U.S. National Park Service, we got permission to use the logos. This gave the DXpedition an exalted status, and you might say amateur radio had its own Op-Sail '76! Why not? This is why the U.S. National Park Service put out the red carpet to us.

Those who went to Liberty Island did amateur radio proud. They were worthy representatives of amateur radio. Without being self-conscious, they furnished the Voice of the Statue of Liberty and gave to a very limited segment of the amateur radio population of the entire world an opportunity to share with us our pride and joy in the Bicentennial. We have to tell you how seriously Joe W9RCJ took the matter. He finally called me at home in Englewood to ask if we were on the air and could we please sked him for 11:00 am on Sunday. Joe, you get the card as soon as Stu K2RPZ gets the negative from me and runs off the 1500 cards we need. There was no need to send an SASE, either. Then we must give Carlos WA2AUV the atta-boy award for trying hard. As we were getting on the ferry to get back to Manhattan for the last time, running down the gangway was poor Carlos, who had missed the one before and was trying to get there to help us out. Better luck next time, buddy . . .

So how about next time? Would I ever do it again? What could we do differently to make it better? What did we get out of it? We would do it again, emphatically! It was a once-in-a-lifetime chance to really do something worthwhile for ourselves and for lots of other people. As it turned out, the gods were kind, and the weather did not turn foul until the Monday after Thanksgiving. You had to dress for it, and be prepared. Different would mean just more lead time and less competition with a long holiday — and more planning ahead. This would assure more operators and transmitters and more opportunities to get QSOs. There is no way to make WL2USA a 24-hour operation without an act of Congress or some very special dispensation from the U.S. National Park Service.

Finally, what did I get out of it personally? Something rare. I got a chance to get to know myself, and what I saw I liked. To carry the ball for an event that goes beyond the boundaries of time and space, to show your pride and convictions and use state-of-the-art technology in the way and place we did it in the way we did it, is something I will be able to recall with pleasure for a long time to come. I hope others that came with me feel the same.

I/O–
a 5 Year Forecast

The general purpose computer industry has a better future in the United States and overseas than previously estimated, according to the Arthur D. Little consulting firm.

The installed base of computers should grow 9 per cent compounded annually in the US and 12 per cent overseas through 1981, the firm said in a recent report.

In its 15th annual five year forecast of the industry, ADL said International Business Machines apparently has recovered from its weakness in its share of the computer business and may become a greater threat to other computer makers.

Increasing profit margins for computer manufacturers also are forecast in the report by Frederick G. Withington and Oscar H. Rothenbuecher of the ADL staff.

Large general purpose computers are not about to be displaced by smaller minicomputer networks, the study said.

Computer shipments will rise rapidly as manufacturers continue making them easier to use, the study said.

Other reasons for the optimistic outlook include "the burgeoning of electronic office and funds transfer systems and the growing use of computers to offset inflation in labor intensive industries."

The installed computer base in the US should rise from about $46.5 billion at the end of this year to $70 billion to $75 billion, and from $40.9 billion overseas to $70 billion to $80 billion in 1981, the study said.

US manufacturers will maintain their dominance of the worldwide market, though it will decrease from 75 per cent this year to 67 per cent in 1981, ADL researchers said.

"The strongest competition for the US computer industry will come from Japan," the study said, noting that country "is making impressive strides toward an integrated, export-oriented industry" and is making inroads in western Europe.

Wider profit margins for computer makers should come from major decreases in manufacturing costs and new revenues from selling systems programs separately from the machinery.

Looking beyond the next five years, ADL says minicomputer networks may become more popular than the huge general purpose machines, though "the two types will live side-by-side for years to come, with most networks requiring a large central host machine.

"The big general purpose machines have a 20 year head start on systems programs," said Withington.

"Small computer networks are not likely to be able to offer equivalent convenience, versatility and stability until the early 1980's. After that the dominance of large computers may wane, but an 'Indian summer' of growth and profitability for them appears likely in the interim."

A Ban on Linears?

If you've been wondering what effects CB is having on ham radio, wonder no more. The plague of outlaw SSB CBers may force an end to the manufacture of linear amplifiers, bring point of sale license checks, and FCC approval of all commercial equipment.

Those are the main points of a staff recommendation due before the FCC at year's end. Chief Engineer Ray Spence, in a *73* interview, said the ban would cover all linear amplifiers, not just those intended for use by CBers. Spence also said he hoped to avoid a ban, by adopting rules requiring dealers to check if a buyer is licensed to use an amplifier. Dealers could be held responsible, and face fines, if they sold to unlicensed persons. Already federal law bans the sale of amplifiers for CB use, but the first conviction under the two year old statute did not come until October. In that case, a Florida CB dealer was fined $250. Legal loopholes, forced by other services, have allowed continued manufacture of the banned amplifiers. The way the law stands, any unit capable of frequencies other than 11 meters is legal, but it's quite obvious what the gear is for, when you consider the 27 MHz receive preamps built into most of them and the 4 to 5 Watt input power. In light of these latest developments, it looks like ham radio may lose more than 11 meters to the CBers. FCC officals emphasize that they have tried everything they can think of to slow down the CB outlaws. Field Operations Bureau (FOB) personnel report illegal activity, despite well-publicized raids in several major cities, is on the rise, not the decline. (In Houston TX, a group of 10 SSB CBers were shut down, revealing the same pattern encountered elsewhere . . . ham transceivers and linear amplifiers modified for 27 MHz, big beams, and enough interference to other services to fill a new BCI-TVI-RFI handbook.)

Engineer Spence, himself an amateur, finds the idea of banning the manufacture of amplifiers "appalling." "It may end up a combination of the alternatives," Spence said, "with equipment approval and point of sale checks becoming law." Others at FCC see no alternative but a ban on amps. The irony in all this is that FCC's attention to the outlaws will only further delay, if not kill altogether, proposals for non-code licenses . . . proposals the outlaws claim they are working for by defying the law. In each issue of *SSB News*, a newsletter devoted to HF and VHF pirates, the editor states, "*SSB News* does not advocate defiance of FCC rules, but we do believe the FCC should act to provide for the needs and wants of the people, to designate additional frequency space on the 11 meter band for sideband hobby operation, and to make a Novice license more appealing by allowing sideband phone privileges for Novices on 10 meters!" (His exclamation mark.)

FCC officials say Class E CB (220

LETTERS

ADAM'S RIB

I am not a ham. Now, wait; don't all of you start jumping on me with both feet, at least not yet. I am one of an ambiguous group known as shortwave listeners, among other things. I have been a (dare I say it?) CBer since 1957 when that endeavor had just been born. Perhaps I should say that it was an Eve drawn from an unwilling Adam's rib. While the OT hams begrudged the loss of the band, it was not quite the dislike held for the lids who run rampant on today's CB channels.

With this introduction, you will assume I am about to engage in a furious tirade against hams or your magazine. Al contrario, I really enjoy your magazine, and still enjoy tuning the bands.

My reason for writing is two-fold. First, I want to disagree with the letter written by K. T. Derek, Pittsfield MA, which appeared in your Dec. '76 issue. If Derek is so against hams, why does he, or she, read *73* or bother writing to you? I read *73* compliments of a good friend of mine, WA1UFE, for exactly the reasons Derek pointed out. I don't find hams either "pompous" or "stuffed shirts," but they are proud. They have reason to be. If Derek or anyone else thinks they could "get a ticket tomorrow" if they wished, I think they ought to try it. I am a holder of a First Class Commercial Operator's License, not through one of these quickie memory schools that simply give the test answers, but through years of hard work, and I am proud of that! I can see that anyone who has studied ardently to get his Novice ticket would be just as proud. For this reason, hams wish to show off a little. I say that's great. You all deserve a round of applause. Anyone can say, "I could get a ticket if I wanted." But it is quite a different matter to actually do it. I would challenge Derek to try it first, before criticizing. It is like watching the tip of an iceburg protruding from the water and commenting, "There's nothing to it" or "Is that all there is?" Believe me, there is more to it than that.

More QRN came from the letter saying that the experimental phase of electronics went out with the 6L6 tube. If you think that, I am sorry for you. I have worked as an electronics design engineer for a big company. The only good designs coming from groups like that are the brainstorm black-boxes that we dream up on our own time. For the most part, the large companies are so wrapped up in sticking to standard procedures that they will not let their engineers develop new ideas on company time. All they are concerned with is cosmetic changes to existing products that have already proven their worth on the money market. Take just one example: the well-known TV games. To my knowledge, the first such unit was a basement "black-box" unit called "TV Tag," in which each player had a dot on the screen and they chased each other around the screen. This wasn't much, but it was enough to make one man go to his garage and build the famous "Pong" game. This started the Atari Company, which is now a big business. Only after the Pong game proved itself a moneymaker did the big companies jump in with hundreds of varieties of the game to get a little of the cream. No, I'm afraid your idea is just QRM.

My second reason for writing at this time, and a more important one to me, is the new *Kilobaud* magazine. I don't want to miss even one issue. If the I/O sections which have been appearing in *73* are any indication, this will be the magazine we have all been waiting for. I do not know what the yearly fee will be, but we can straighten that out later. Please put me down for a year's subscription, starting with issue number one, and bill me. Tnx.

MISSED POINTS?

I must compliment your policy of printing everybody's views, however far off base they may seem. At the same time, I can't resist commenting on G3OGR's article in the December issue. I'm afraid, however, that it was ill-timed — it would have been more appropriate around the first of April.

Seriously, though, lest some beginner misinterpret the article, some form of analysis is necessary.

He was trying to prove or disprove the effectiveness of correct antenna matching in terms of radiated signal strength. He started with an antenna, cut to resonance, evidently, according to the basic antenna formula. However, he had no way of knowing the antenna impedance with which he was starting. This factor varies with wire size, wire type, physical orientation of the wire, its height above ground, and the conductivity of that ground. He points out that, with the wire going directly into the transmitter output, he was able to get a resonant condition. Well and good. Luckily the wire was within the range of the transmitter's output network, and so needed no tuner in the first place. Nonetheless, he noted plate current and antenna current. Fine. A given power into a given impedance produces a given current—Ohm's Law.

When he added a tuner, he had to change the settings of the transmitter's output network; consequently, the transmitter's output impedance was different. The tuner then transformed this new transmitter output impedance to the antenna impedance, which was the same as before. Same plate power, transformation through the transmitter output circuit to a lower impedance, then back up via the tuner to the same antenna load impedance as before. Pi-network and tuner resonated, little or no power loss, same antenna current, of course! All he proved was that the tuners do work. He varied the transmitter output settings and brought them back up to the antenna impedance with the tuner.

When he changed antenna length, the antenna current was different because the antenna load impedance was different. Since he was matching the new antenna impedance to his transmitter, and then putting the same power into the antenna, of course his radiated field stayed the same.

Now, when he mistuned his tuner to get a 5:1 vswr, and then put the same current into the antenna, he failed to say whether his plate current dipped to the same level or a different level — he only says that it dipped. I certainly hope he didn't operate for long under those conditions, since with a 5:1 swr, nearly forty-five percent of the power being generated was heating up the plates of his output tubes.

He noted that the antenna apparently changed the values of L and C required for resonance. Antennas do that. Depending on length, they add either L or C to the circuit.

His closing remark was quite correct. No tuner made will add S units to your signal. They only transform the antenna impedance to known values so that you can go into your equipment with coax of known value, and little things like interference filters will work. Also, when the swr is low, all the power being sent to the antenna is staying there. The tubes last longer and you don't have as much TVI, or as much rf floating around your shack. There is no myth to that. To increase radiated field, you must put more power into the antenna.

In conclusion, I want to emphasize that I'm not trying to pick the guy apart. He had the courage to experiment, which few hams do nowadays, and he had the pride to write his conclusions. My only criticism is that he seems to have missed a point or two in his evaluation of those experiments.

Bill Hood W2FEZ
Albion NY

G3OGR REPLIES

W2FEZ seems to be making some points I made, but in other words. The article does *not* cover the need for a flat line for harmonic filter, etc., but the fact that end-fed antenna length is unimportant in the terms described, and losses if any in using it as a load via an ATU. Without repeating it all, perhaps I can make my point again briefly. An end-fed wire does not need to be cut to resonant length in the interests of radiation. This is easily proved as described.

On the point of a high swr in a line from the pi tank, this does not of course cause 45% loss at 5:1, or virtually any loss. Assume the wire is fed directly from the tank, and tank values allow its impedance and reactance Zj to be suited; then maximum swr equals maximum antenna power. Now suppose the tank is engineered for 50 Ohms. We use L and C to suit, and able to take the calculated voltage and current. We may not be able to use this at some high value of Zj because excursions will exceed component ratings. But we could engineer the tank for any load, with the same output power. If we had enough L and C rating and adjustment, the tank could be used with 50 Ohms, 1k, or anything, with reactance too. I have fully adjustable pi tank, coax to swr indicator, coax to antenna tuner, antenna current meter, then antenna. Radiated power is the same for 1:1 swr as for 5:1, 8:1, or any other figure. This is readily proved in the terms described, which once again are nothing to do with the need for, perhaps, under 2:1 swr to avoid damage to a tiny transceiver tank, or matters such as TVI, etc., which were not the subjects covered.

GRATITUD

4259 Bedford Ave.
Brooklyn NY 11229

Dear Larry,

I don't know what this letter will mean to you. But this in all sides a great testimony of real Gratitud. Why ...? Well I say that one must be grateful for those peopple whom teaches us anything, even if this is only to put the table in the correct place. I haven't find too may Intelligent peopple in this rotten world. I'm shure that you are one of them; many technician know a lot about Electronics, but they have many tricks in their brains if they have any brains. This (I call tricks, only because my English is very short ...) avoids them to think correctly and to "give" others what they have. You call them Selfish ...? or egoist dogs. Thanks again and read this ...

I do not know how the counters count ... I pretend to make one for me, but this is almost impossible at the moment. I'm a very old 53- man, and although I work almost in any branch of Electronics this Digitals are new for me. I haven't too meny books about it and if any, they cover the line in a very rough manner, so its not easy to understand them, many as you know cover "the way to make them" (?) do I want to make them ...? Or

. . . how many technicians you know who want to make IC's . . .?

But YOU GO TO GROUND EXPLANATIONS, You make your things for very Stupids like Myself, and this is the way we need it.

This letter in the other way, is to ask you to GO ON. Even if you write only for me (I don't thik so) Just keep on. You have somebody who reads your articles with avid curiosity. I wait the mail every month, to keep my subscription to the best Amateur Mag. and see what new things I learn about digital affairs.

Keep ON again, just tell us HOW THE THINGS ARE MADE. Because I know how divider, or better What dividers make, But how . . .? What means Enable . . .? And so on . . .

I'm in Electronics since 1935. A real proffesional since 1938; I can make almost anything in the row, this is really something NEW for me, and I do not learn very fast by now, and I have many things I want to learn, in one word Larry, Medical Inst. and Industrial Controls are by now absolutelly Digital. Signal tracing is my system, but first I must learn what they are to see any signals. The world will be Digital . . .! Or is it allready . . .?

Again . . . How an divider, divides . . .? How an Flip Flop makes the thing . . .? You told me about. Now just give us more, you can make a complete description of a counter and how can I use it and most, how can I make one . . .? The list may be very long and very tedious to you, practically anything you can make will be quit welcome by many in any part of the world *73 Magazine* goes.

Good fellows like you, make *73* very atractive, very very atractive. We learn . . . and that's why and enough. Rather than having any Magazine with a lot of "Boxes", and also many explanations, I never read. I'll get *73* for as long as I can get anything from reading it. You are the first I read, Really HONESTLY SAID. All other magazines for Amateurs are very dificult to follow, for they make articles Absolutelly Imposible to copy, if they are not very expensive, they are too complicated and not always are with easy instructions to follow. Besides if they are not interested in Mexico, just why they send the magazine to us . . .?

Amateurs are beautiful, They make a lot of things "Without any Engineering". My contact with them is for I make repairs in any SW receiver or Transmiter. I'm not active because the rules in Mexico are very misadjusted. They want me to learn 5 words per min. in Morse Code . . . And I'm very old for learning anything I consider OUTSIDE OF ELECTRONICS. I argue to them that is more necessary to make to learn any guy whom makes an aplication for amateur, and more important to know, what they can make with 1000 Volts, and what they should NOT to do, and that this H.V., simply Kills. Those I remember long time ago, are Dead . . . because High Voltage Kills for ever, and nobody told them So.

Well dear Larry, (May I call you, Just Larry . . .? You call me Bill. This is the translation to English of my name which is Guillermo), I have friends all over our continent. Your contact with *73 Mag.* makes one of my best.

At least one man in Mexico, as I know is waiting for your writings and remainds you not to forget the next article to *73 Magazine*. I'll be waiting . . . Good By Larry, and remember again . . . We need your articles . . . Keep going ahead, give us more to read about Digitals. Many guys like me, need them. And I think this is all over the American Continent.

Guillermo Moreno Rivas
Sindicalismo # 87-219
Escandon Z 18
Mexico

You know . . . it's letters such as this that make it all worthwhile. I have gotten many letters which thanked me for the articles, but this missive is most sincere.

It speaks not only for my efforts, but for yours as well. You print them.

Larry Kahaner AB2NEL
Brooklyn NY

LESSONS FOR ADSIT

I've just finished reading Norbert Adsit's article, "Design Your Own PC Boards — the styrofoam solution," in the Holiday edition of *73*. I'm still smiling. Some time ago, I made my first PC board. A lot of time and effort went into its design and fabrication. That board ended up in the garbage can because I hadn't kept in mind that if you design the board from the component side, you must reverse everything from right-to-left when you transfer the design to the foil side.

It was a hard but enduring lesson and one that Norbert Adsit needs to learn.

For anyone who jumped in and made a board following the system proposed in the article, I believe they may be able to salvage their boards if they will mount the components on the foil side. Their soldering techniques will suffer since the components will block free access to the leads. The end result will look a bit primitive but should be serviceable.

For those who are adventurous, I suggest that they go ahead and mount their parts on the component side of the board. They will need to be extremely careful about making sure they are using the right holes since they won't be where they laid them out. I believe components with two leads can be handled easily enough if special attention is paid to polarity sensitive components such as diodes. Those parts with more than two leads, like transistors and integrated circuits, would require fairly drastic measures. In essence, these components would need to be placed upside down on the board and their leads bent back down into the board. This would be risky since it would be easy to break some of the leads or to get confused as to which lead was which.

I would use these methods only as a last resort. But for those who invested their time and energy making boards with Norbert Asdit's system, these ideas may have some value.

D. E. Stanfield
Atlanta GA

NORTH OF SIXTY

Just a little note from "North of Sixty" to commend *73 Magazine* and some of its advertisers. In addition to S.D. Sales, Godbout, and James Electronics, please include Bullet Electronics and Quest Electronics, who also give very good and speedy service. Bullet's kits have well-made, very small PCBs and, although some of the parts are not always easy to identify, the kits go together well and I have had no problem in getting them to work.

Nice to see that you have gone to the tear-out Reader Service card; sure is much better than having to cut a chunk out of the pages which made a mess when one collects the magazine and likes to keep it in as good condition as the Postal Service delivers it in (Ugh).

It's also very pleasing now to find that certain of the articles now have a source or printed circuit boards available; this is really a boon to would-be constructors who do not wish to fabricate their own.

Really like your magazine here — good easy to read articles, mostly easy to make projects, and a bit of humor thrown in.

73 and keep up the good work.

F. V. (Vic) Greenleaves VE8AM
Whitehorse, Yukon

OLD HAT?

I'm sure an all ham radio wedding is old hat by now. But, I thought you might enjoy this picture. For us, it's the best in the album. As yet no one will confess to the artwork, as the "HT" wasn't there when we arrived at the church!

TECH REAX

I have been subscribing to your fine magazine for about three years now. Your articles and editorials are always interesting, and it is good to have someone such as yourself who can articulate what I'm sure many of us think and feel.

I would like to respond to your editorial in the December issue concerning support for Tech class operators on 10m. You posed several questions that I feel can be answered. The absence of activity on 220 is because there is basically no advantage or difference over two meters. If one already has 2m equipment, there is no practical reason to want to get on 220 since the range and type of operation is primarily identical. I think this also goes for the other VHF frequencies. Incidentally, I'm talking about the average everyday Tech class operator, and not about the more admirable (but rare) type who has the ambition and facilities to experiment with new and higher frequencies just for the sake of experimentation. Since 2m is the first band most Technicians get on, they stay there because there is no incentive to go elsewhere.

However, six meters is an entirely different case. From firsthand experience, I firmly believe the main reason the band is empty is the difficulty with television interference. 6m sideband would be great, except that most people live in subdivisions and not in the middle of a twenty or thirty acre farm. When half the people within a mile or two of you are running rabbit ears and trying to watch football on channel 2, any talk of high pass filters, low pass filters, and quarter wave twinlead stubs, etc., becomes purely academic. With the TV's AGC running wide open to bring up a weak TV signal, the only place for a filter would be the antenna lead's connection to the chassis inside the set. I don't have to spell out the time, expense, liabilities incurred, etc., involved in clearing up TVI for 50 or maybe even 100 cases such as this. Other options available might include letters and/or visits from the FCC, as well as explaining to the lynching

party on your front lawn exactly why it is necessary for you to regularly interfere with their favorite pastime. Thus, the only band available to Techs which even marginally offers any promise of DX, WAS, and all the other goodies associated with low band operation, comes out looking pretty dim when compared with its disadvantages. Therefore, when given an even halfway attractive alternative, most Technicians will take it, and there you are again up on 2 chewing the rag unobtrusively with some other Tech who lives across town instead of across the country.

Now comes the question of why the 200,000 General and above licensees don't flood onto ten with rag chews and DX pileups. It is a matter of relative value. They already have 75, 40, 20, and 15, with good antenna setups, nets, scheds, and a lot of friends on their favorite frequencies. They simply don't need 10m for their enjoyment of ham radio. In much the same way that Techs have no reason to move to 220, a General class licensee feels no compulsion to rush up to 10. The situation could be compared to offering a 79 cent bottle of Ripple wine to someone sipping on a case of champagne. He probably won't knock you down to get it. However, offer the same bottle to a wino with the Monday morning shakes and see what happens!! Similarly, Generals or above perceive 10m to be inferior to the other HF bands available to them because of erratic propagation or some other reason. This is not a value judgment of my own, but is based on the amount of activity found there. On the other hand, 10m would be extremely attractive to a Tech class operator because it would be the only HF band available to him. Also it would be far enough from television frequencies so that those problems could be handled in the conventional manner if they arose at all.

Finally, one could argue that SSB privileges for Techs on 10m might encourage some percentage of them to upgrade. CW is not every man's game and many people probably won't spring for the five or six hundred dollar tab associated with most 5 band transceivers just for Novice privileges. Many of those same people might, however, if they knew they could operate phone on at least one band while improving their code speed on the others. This would provide a strong incentive to upgrade since they would already have paid for the equipment, and all that stands between them and its full utilization would be the increased code proficiency. In addition, a few hundred purchases of rigs based on this premise certainly couldn't do our economy any harm, could it?

I have tried to confine myself to the topic of behavior and facts related to life in the real world. Discussions of whether a person should be "given" something when others have "earned" it, etc., are an entirely different subject. Similarly, questions such as, "If you want it, why don't you just get up to 13 wpm . . ." are not related to this discussion. Most people behave in a rational manner; that is, they expend effort only if they perceive the benefits to be worth the time and work required to achieve the goal. Evidently, there are a great many Tech class hams who don't perceive the increased privileges as being worth the effort involved. As ignoble as this may seem, it is still a fact borne out by the number of long time Technicians who have held their licenses for ten or fifteen years.

However, based on my own experience and conversations with others, there is still a strong desire to engage in HF type operation by most Technicians, and ten meters would attract many of them if the regulations allowed it. After all, that is the important thing — to get a significant number of ham operators on ten meters.

Thank you for giving me a chance to express my opinion.

Keep up the good work.

L.N. Thompson WB4WNV
Austell GA

EXTENDED BASIC

A helpful note regarding Joe Kasser's fine program in the Nov. *73* is that if anyone runs this program in Altair Extended BASIC, the variable "MODE" in lines 600 and 615 will conflict with a reserved variable MOD. Just change MODE to another variable such as M5 and the program will also run in Extended BASIC.

Keep up the good work.

John DuBois W1HDX
Boxborough MA

KANGAROO COUNTRY

I enclose $20 in US funds for a 3 year extension. I like the present format; it's very good. Thought the "Eyes for Your Shack" in Nov.-Dec. '75, one of the best articles that I have ever seen published. I like articles on advanced test gear very much; more please from the same author. Have had very good results from Bill Godbout, Poly Paks, James, and Gateway, on mail orders.

Greetings to all the *73* staff from "Kangaroo Country."

Wally Payne VK3YP
Victoria, Australia

A SIMPLER SOLUTION

All good credit to K5AR/7 regarding the "Turn Signal Reminder" on p. 166 of the Holiday issue of *73.*

Several years ago I found a simpler solution: I connect the Sonalert directly across the terminals of the turn signal flasher. Polarity must be observed, of course.

I found it necessary to muffle the unit by wrapping it with tape. My co-pilot objected furiously!

Chester L. Doll KØPTG
Omaha NE

FT-101 uP??

I don't know much about micro hard and software, and it'll be a while before I can afford a system, but you can bet your floppy disk I will be keeping *73* I/O and the new *Kilobaud* mags on my reference shelf for a long time!

Think of the future uses of computerized ham radio! How long will it be before microprocessor based transceivers are put on the market? Auto ID . . . processor-based CW/Baudot/ASCII system . . . "punch-up" frequency selection . . . a new mode?? Who knows, a Yaesu FT-101 uP???

Keep fightin', Wayne; we'll get our way yet.

Mark Herro WB9LSS
Oconomowoc WI

LIFE

I am pleased to become finally, after at least ten years, a lifetime subscriber to *73 Magazine*. You have pushed and prodded me on many occasions into trying new and exciting innovations appearing in the field of electronics. It was because of your insistence that I finally started into two meters, and I have been glad, of course, ever since. With the advent of *Byte Magazine*, I renewed an interest in computers and shortly thereafter purchased one which I have been using ever since. It is proving to be a source of continued inspiration and intellectual challenge both to me and my 13 year old son who is now the acknowledged computer program debugger of his school.

So I owe indeed a great debt of gratitude and thanks to you for all your encouragement, albeit indirectly.

With best wishes for a happy, healthy and prosperous New Year.

Gerald E. Meltzer M.D. WØFFC
Aurora CO

MICKEY AND FOXY

Thought I'd give you a bit of background. I, Mickey, am a hardware person, and my wife, Foxy, is a software person. Until the advent of microprocessors, I had always considered software to be "woman's work" (being a good MCP, as the women's libbers might say). I have an Advanced class amateur license and a First Class Commercial Radiotelephone License with Radar Endorsement and am employed in electronics by Ma Bell (sorry 'bout that!). After the Atlanta Hamfest this year, I came home and told Foxy that I wanted a computer. Contrary to what you might expect, her reaction was somewhat akin to my having said, "Robert Redford is going to spend a few days with us!" You see, my wife has had about 6-7 years of programming the big monsters (ISM, Univac, etc.) in COBOL and Assembly languages.

We discussed (argued) extensively as to what constituted a "minimum acceptable system," finally deciding that it was: 1. No bootstrapping allowed; 2. Minimum of 16K RAM; 3. Minimum two tape machines; 4. Hard copy printer; 5. CRT control terminal. Then we decided on a maximum of $1500 total system cost. The problem of which computer system was therefore very easily resolved; only from SWTPC could we purchase our "minimum acceptable system" for our "maximum total system cost" or less. On July 22, 1976, we took delivery of an M6800 computer, AC30 cassette interface, CT1024 terminal, and PR-40 printer from Atlanta Computer Mart.

Once the assembly of all the kits was completed, I felt that the fun was over, so Foxy gave me an operating system as a project. She helped in the "blueskying," and gave some help and encouragement when I got stuck (also helped in putting an article together), but mostly let me work it out for myself. So I must share the credit for the OS.

Mickey (and Foxy) Ferguson
Trenton GA 30752

Mickey and Foxy have put together a rather impressive Operating System for their 6800 and their article on it will be in an upcoming I/O section. A tape of the program will be offered through the 73/Kilobaud Software Library, also. – John Craig.

HOOKED

This letter is going to be a combination of things, as I've put off writing this for a long time, and the things I want to say piled up.

First, I want to add my praise for James Electronics to that of John Dieringer W6RVP. Their service is not only outstanding, it's phenomenal. I've ordered from them three times now, and in each case have received my parts back in *five* days. They must have employees waiting in line to fill orders. Keep it up, guys.

Second, tell Mary in Reader's Service not to despair; I finally noticed the little card in the back of your mag and decided to send it in.

Third, keep the digital (and *anything* on microprocessors) stuff rolling in. When I first subscribed to *73* this summer, I read the first issue and about cancelled my subscription. Where were all those pages upon pages of thrilling contest results? Instead, you had printed articles about incomprehensible boxes called microprocessors. Well, you've got me hooked now, and although I haven't got a computer, I'm about ready to subscribe to *Kilobaud*, out of sheer curiosity, if not interest. Those computers are getting more and more comprehensible with every issue. But I'd still love a book on the basics: programming (BASIC), memories, interfacing, peripherals, the codes used (what the heck are Baudot and ASCII?), or in short, anything for a newcomer. A tall order, Wayne, but

Continued on page 86

BE MY GUEST

visiting views from around the globe

from page 6

MHz) is dead for the moment because of the 40 channel expansion and strong objections from other services. However, the Communicator Class proposal (Docket 20282 . . . 220 and above without code) is still being actively considered. FCC officials admit that both proposals are in limbo, while the CB problem takes their attention. They also emphasize that the impact on ham radio will be as minimal as possible. Nevertheless, it's clear that amateurs can no longer stand on the sidelines and watch the wrestling match between the FCC and CBers. There is more at stake now than Novices or Technicians with 10-4 accents. Our frequencies, amplifiers, and status with the FCC may be in jeopardy.

So what can we do about it? For one thing, amateurs everywhere should promise themselves that they will reply when the FCC asks for comments on the amplifier docket. There *are* some alternatives. How many ham rigs are capable of 10 meter operation? In the Holiday issue of *73*, 25 rigs are advertised with 10 meter capability. Only two of them operate with less than 200 Watts input. Consider the fact that the linears FCC is worried about average 2 to 4 Watts input, 100 to 250 Watts output. How about a rule requiring all linear amplifiers to have a minimum drive power of 100 or 150 Watts? Another alternative would be frequency coverage. How about limiting amplifiers to frequencies below 21.350 MHz? Remember, no matter what the FCC finally decides to do, home brewing will not be outlawed and existing equipment won't be affected. So the effects on ham radio *can* be minimized, if we all get off our tails and react constructively when the FCC requests comment. As one FCC official told *73*, "There are millions of CBers operating with illegal power or out of band . . . compared to the thousands of hams capable of using 10 meters with amplifiers, ham activity on 10 meters is a drop in the bucket . . ." Why not help flood the FCC's bucket . . . and turn the amplifier ban against the illegal CBers? Think about it. (Recent change in FCC procedures only requires an original and 5 copies instead of 13.)

Handicapping the Handicapped

With the large number of people becoming interested in amateur radio, an increasing concern for the FCC is arranging exams for handicapped persons who are able to travel to examination points but unable to take the test in the conventional way. Although the FCC did do away with Conditional class exams last year, those unable to travel can take the exams at home for Technician, General, Advanced, or Amateur Extra when a physician's certificate shows them incapable of the trip. Another change in the rules: Instead of the applicant picking his own volunteer examiner, that choice is now made by the FCC.

With blind or deaf prospective hams, the situation is a little different. An FCC spokesman told *73* that a formal testing structure has been in existence for the blind for a number of years. The code exam is the same, but the written test is done in one of two ways . . . Braille tests are available or the exams are read to the applicant by the FCC examiner. In both cases, schematic diagrams are eliminated.

The plight of the deaf applicant is the most difficult of all. In their case, the FCC makes no provision for a CW test. The FCC told *73* that according to the way international regulations are worded, the applicant is required to *hear* CW in order to obtain a license. This creates a sticky problem for the FCC, who must give the applicant a waiver from hearing the code, while still requiring them to pass the code exam. FCC field offices have no equipment for non-aural copy of code, so the applicant is forced to furnish his own means of transferring the FCC exam tape into a medium he can copy. The most common method used, according to the FCC, is some sort of homebuilt device that changes the sound into vibrations using a buzzer or speaker arrangement. Lights can be used; however, the slow damping factor of regular lightbulbs makes them impractical for speeds of over 5 words per minute. LEDs, because of their almost instant damping, should be usable to higher speeds, although no data on their use in this type of application is available.

The FCC told *73* they have no present plans to make provisions for deaf applicants because, as yet, their numbers are extremely small. No estimate was available on the number of handicapped amateurs in the country, and a check with the FCC field office in Boston disclosed that the examiner there had never given an exam to a deaf person.

Although deaf people represent a very small percentage of the population, and those who wish to become hams are an even smaller number, it seems the FCC should make some provision to help these people deal with the examination process. Nondiscriminations laws are in existence to help those who would otherwise be discriminated against because of their handicaps, and if the FCC is unable to do this, perhaps one of our readers could help with plans for an inexpensive sound-light or sound-vibration unit.

Those wishing further information about waivers required should write to The Chief of Rules and Regulations, Amateur and Citizens Division, Federal Communications Commission, Washington DC 20554.

Inside the "Big Noise"

What is the "Big Noise" and what is its purpose? Those questions have been generating a tremendous amount of speculation since the appearance of the noise last summer with its subsequent disruption of radio communication throughout the world.

The sporadic interference has been heard throughout the HF spectrum from 2 to 24 MHz. Signals last anywhere from thirty seconds to half an hour, are pulsed at 10 Hz, and have been measured with bandwidths of up to 300 KHz.

Theories abound on the noise, the most common holding that it's some sort of propagation study. High-placed sources decline comment on the purpose.

Other theories range from HF radar to a new navigation system. The latter was backed by an FCC spokesman who said that although direction finding is very difficult, because of the large distance involved, the FCC believed the noise is coming from at least two transmitters located in the Minsk area of the Soviet Union, about five hundred miles west of Moscow.

A logical theory was put forward by George Jacobs of the Board for International Broadcasting in Washington. He theorized the Soviets might be testing parts for a new high powered transmitter and added that if the U.S. were building such a unit, we would be doing the same type of testing.

The noise disappeared for nine days during the middle of November and was believed to be gone for good when it abruptly appeared again. According to FCC Chief of International Operations Robert Cutts, the Commission sent 5 informal complaints through the Soviet embassy since the noise began. He added that a reply was not expected since the Soviets seldom even acknowledge receipt.

With the noise continuing as strongly as ever, the FCC asked the State Department to issue a formal complaint, the next step on the ladder of protocol. As that complaint was being prepared, an unexpected event took place – the Soviets replied to the FCC's complaint. The tersely worded statement from the Soviet Union called the noise an "experimenal use of the radio spectrum which will be terminating shortly." There was no further indication as to when the noise would be cut off or of its purpose. The Soviet embassy in Washington said that they were "aware of the situation" and declined further comment.

The Soviets' admission caught government officials completely by surprise and left them mystified. An FCC source theorized that the Soviet statement was the result of heavy political pressure coming from all over the world. Being extremely close to

Special Report

by Warren Elly WA1GUD

It is most important that the material in this 73 Special Report be kept in the right context. The FCC draft must now withstand public comment (the deadline is January 31, 1977) before becoming final. It will then move on to other WARC sessions on an international basis, prior to the 1979 conference. The US, like all 100 countries envolved, has only one vote . . . and therefore the FCC's proposals carry a lot less weight than they may seem to on the surface. The frequency table does, however, offer an updated perspective on the FCC's feelings about amateur radio and CB, especially when one considers the 220 MHz allocations, and references to mobile services throughout the table.

THE BUZZWORDS

ITU — The International Telecommunication Union, whose regulations govern communications on a worldwide basis. 150 countries have agreed to be bound by ITU and its all-important table of frequency allocations. The ITU is directed by an Administrative Conference held each year, which can call for regional or general membership meetings on an "as needed" basis. It takes a vote of the ITU members to call such sessions. Every 7 years ITU holds a Plenipotentiary Conference of the membership, which in turn can call a world conference (WARC).

WARC — The World Administrative Radio Conference, held as necessary at the call of ITU members. WARC is the big one, where international allocations are decided.

IARU — The International Amateur Radio Union, ham radio's international lobby, with 90 societies representing nearly all licensed amateurs in the world. The IARU doesn't just lobby with ITU and during WARC; it also serves as ham radio's contact with the governments of each country, usually through their communications ministry or FCC equivalent.

Region 1 — The area including eastern and western Europe, Africa, the Middle East including the entire Saudi Arabian peninsula, all of the Soviet Union and Mongolia.

Region 2 — The Western Hemisphere including Greenland, but excluding Iceland.

Region 3 — What's left: the South Pacific, Southeast Asia, and Oceania.

The Breakdown

BAND	EXISTING (Region 2)	FCC (Region 2)	STAFF RECOMMENDATION (ARRL)[1]
1875m	no allocation	160-190 kHz exclusive *amateur*	160-190 kHz
160m	1.8-2.0 MHz subject to regional restrictions	1.750-1.9 MHz[2] *amateur* shared with fixed, mobile, aeronautical radiolocation and navigation	1.715-2.000 MHz
80m	3.5-4.0 MHz shared with fixed, mobile, broadcasting	3.5-4.0 MHz *amateur* exclusive through 3.9 MHz[3]	3.5-4.0 MHz
40m	7.0-7.3 MHz shared with broadcasting	6.95-7.3 MHz *amateur* exclusive,[4] *amateur satellite*	7.0-7.5 MHz
20m	14.0-14.350 MHz	13.950-14.400 MHz *amateur exclusive amateur satellite*[5]	14.0-14.5 MHz
15m	21.0-21.450 MHz shared with maritime mobile, fixed	20.7-21.2 MHz *amateur, amateur satellite* exclusive	21.0-21.5 MHz
10m	28.0-29.7 MHz exclusive	28.0-29.7 MHz *amateur* exclusive, *amateur satellite*	28.0-29.7 MHz
6m	50-54 MHz exclusive	50-54 MHz *amateur* exclusive[6]	50-54 MHz
2m	144-148 MHz exclusive	144-148 MHz[7] *amateur* exclusive, *amateur satellite*	144-148 MHz
1¼m	220-225 MHz shared with fixed, mobile, radiolocation, aeronautical, broadcasting	220-225 MHz *amateur, amateur satellite*, radiolocation, mobile[8]	220-225 MHz
¾m	420-450 MHz shared with radiolocation	420-450 MHz[9] *amateur, amateur satellite*, shared with radiolocation	420-450 MHz
3/8m	no allocation	902-928 MHz fixed, radiolocation, primary; *amateur*, mobile, secondary	902-928 MHz
1215 MHz	1215-1300 MHz	1215-1300 MHz radiolocation, primary; *amateur, amateur satellite*, secondary	1215-1300 MHz
2300 MHz	2300-2450 MHz	2300-2450 MHz radiolocation, primary; *amateur*, secondary	2300-2450 MHz
3300 MHz	3300-3500 MHz	3300-3500 MHz radiolocation, fixed, fixed satellite, primary; *amateur, amateur satellite*, secondary	3300-3500 MHz
5650 MHz	5650-5925 MHz	5650-5925 MHz radiolocation, primary; *amateur, amateur satellite, secondary*	5650-5925 MHz
10.0 GHz	10.0-10.5 GHz	10.0-10.5 GHz radiolocation, primary; *amateur*, secondary	10.0-10.5 GHz
24 GHz	24.0-24.250 GHz	24.0-24.25 GHz[10] *amateur, amateur satellite*	24.0-24.250 GHz
48 GHz	48.0-50.0 GHz	no amateur allocation[11]	48-50 GHz
71 GHz	71-84 GHz	71-76 GHz radiolocation, primary; *amateur, amateur satellite*, secondary	71-76 GHz
152 GHz	152-170 GHz	165-170 GHz radiolocation, primary; *amateur, amateur satellite*, secondary	165-170 GHz
200 GHz	200-220 GHz	no amateur allocation	no proposal
240 GHz	240-250 GHz	240-250 GHz radiolocation, fixed, mobile, primary; *amateur, amateur satellite*, secondary	240-250 GHz
300 GHz and above	300 GHz and above	no international allocation proposed[12]	300 GHz and above

[1] *The ARRL had proposed additional bands at 10, 18, and 24 MHz, all of which were left out of the FCC final draft (see text).*

[2] *In regions 1 and 3, the FCC proposes 1.725-1.750 MHz, which would in essence be another "DX window." "It cannot be readily determined whether or not worldwide allocation of these bands to the amateur service is practicable due to the lack of knowledge regarding spectrum requirements in other regions." — FCC WARC draft.*

[3] *In regions 1 and 3, 3.9-4.0 MHz is shared with broadcast, fixed, and mobile.*

[4] *In regions 1 and 3, 7.1-7.3 MHz is shared with broadcast.*

[5] *The FCC draft calls for amateur satellite allocations only between 14.0-14.250 MHz.*

[6] *In region 1, broadcasting is allocated between 47-68 MHz.*

[7] *In region 1, fixed and mobile is allocated between 146-149.9 MHz. See text for aeronautical pressure on 146-148 MHz.*

[8] *Class E CB is left in the FCC document under the mobile classification "To provide for extensive development of amateur satellite techniques; to provide for the expanded land mobile need." — FCC WARC draft (see text).*

[9] *There is no amateur allocation proposed for region 1 between 440-450 MHz.*

[10] *Amateur and amateur satellite are primary between 24.0-24.05 GHz; only amateur is allocated between 24.05-24.25 GHz as secondary to radiolocation.*

[11] *The FCC draft calls for reserving 48-50 GHz for aeronautical and maritime services.*

[12] *Although the FCC is proposing no international allocation for 300 GHz and above, WARC is not expected to affect amateur and experimental use domestically.*

The Analysis

1875 METERS

With the announcement of the FCC's proposal to introduce to the WARC a recommendation that hams be allowed to use the frequency band between 160 and 190 kHz, the possibility now exists that within a few short years amateurs may be able to explore a whole new area (to us, anyway) of the radio frequency spectrum. Although similar in nature to medium frequencies, the low frequency band is much more sensitive to atmospheric and electrical noise. Propagation is primarily by ground wave; however, skywave is possible.

Traditionally, LF equipment has employed large rf coils and tuning capacitors for high-Q selectivity. With the advent of integrated circuit operational amplifiers, however, miniature high-Q stages are now practical. Direct conversion "synchrodyne" receivers are also effective in this portion of the spectrum.

Conventional antenna practices have historically been used at low frequencies; most early long wave radio stations used high and large wire antenna systems. Because of the long wavelengths involved, indoor loop antennas are often satisfactory as receiving antennas, as they encounter a minimum of phasing and reflectivity problems. Often, a vertical ground or roof mounted whip is highly satisfactory. A good ground at these frequencies is mandatory.

The most that can be said of the proposed new 1875 meter band is that it will be similar to 160 meters, only more so, and if you like 160, you'll love 1875. I wonder who will be the first to work 100 countries on the new "Top Band" (if we get it)? *Includes excerpts from 73's forthcoming publication, "Communication Monitoring" by Robert B. Grove.*

160 METERS

With increased interest in the 160 meter band, due to the current decline in the sunspot level, many eyes will be turned to the WARC to see what will be the result of its action concerning the band many in the hobby affectionately refer to as "Top Band." The FCC proposal to the WARC contains what may at first glance look like a net loss of 50 kHz. However, after analysis, this may not be the case. The "new" proposed 160 meter band would run from 1750 kHz to 1900 kHz, with the bottom 50 kHz being coequal primary with direction finding. The top 100 kHz would be exclusive amateur and not shared with Loran as is currently the case. At present, 44 percent of the amateurs within the US in the states of AK, AZ, CA, CN, ME, MA, NV, NH, NJ, NY, PA, RI, VT, WA, and OR are not allowed to operate above 1900 kHz, and a majority of these hams are only allowed to operate in a 50-75 kHz section of the band below 1900 kHz. Therefore, by opening the entire 150 kHz 160 meter band to amateurs throughout the entire US, this would in effect be a gain to most "Top Band" users.

80 METERS

The FCC plan leaves 3.5-4.0 MHz the same as it is now. Between 3.5 and 3.9 MHz, amateur allocations will be worldwide exclusive, with only two exceptions. Above 3.9 MHz the FCC proposal allows for the same sharing with SW broadcast as now exists . . . as an FCC spokesman put it, "The existing character of 75 meters will remain . . ." The top segment of 80 meters remains threatened, however, with the SW broadcast interests pushing for the upper band.

40 METERS

If you're a 40 meter man, you'll love the FCC proposal. The lower end of 40 would go down 50 kHz to 6950, with the first amateur satellite frequencies starting there (for downlink purposes). From the new band edge through 7100 kHz allocations would be exclusive amateur, but SW broadcast would continue to enjoy its stranglehold over 7100-7300 kHz. There are some indications that the Soviets, at least, are becoming less interested in SW broadcast, and it's hoped by the time the WARC allocations get into practice the broadcast QRM may be abated. Another unanswered question is what the FCC will do about domestic sub-bands within the allocation. The debate of CW vs SSB is far from over, and 40 meters will be a battleground comparable only with 20m.

20 METERS

If you were to rank the HF ham bands in order of international importance, 20 meters would probably come out on top. And if the FCC proposal becomes a model for WARC, there may finally be some relief from the Sunday afternoon madness on 14 MHz. The FCC plan calls for 100 kHz worth of expansion, stretching 20m from 13.950-14.400 MHz. The entire band would be exclusive amateur, allocation-wise, with 14.0-14.250 a satellite band in the FCC plan. Again comes the question of how the FCC might divide the new segments, but first we have to get them at WARC, so it's tough to get a reading from Washington. Sources say, however, if amateur radio is to get anything out of the conference, the 20 meter expansion will probably be it.

15 METERS

A lot of the initial reaction to the FCC WARC plan has focused on 15 meters, largely because it is the most radical change for HF. The band would be moved down 300 kHz, to 20.700 MHz, while the top end would come down from 21.3 to 21.2 MHz. A gain of 150 kHz, with satellite authorization to boot . . . but a lot of fellows reacted negatively, arguing that their equipment couldn't make the hike. (Actually a pretty weak argument, if you think about it.) On the plus side, the new 15 meter arrangement would put us that much further away from fixed allocations at the top end of the present band.

10 METERS

There is no change in the FCC plan for 10 meters over current allocations. The band would remain 28.0-29.7 MHz on an exclusive basis, with amateur satellite sub-bands. Nearby, on 27 MHz, the FCC plan calls for the so-called ISM (Industrial-Scientific-Medical) and Fixed-*Mobile*. The key word there, of course, is mobile, which means CB for all practical purposes.

6 AND 2 METERS

The FCC proposal leaves both 6 and 2 meters as is, with exclusivity and the same frequency allocations. The major issue here is on 2 meters, where the international aeronautical community is fighting for 146-148 MHz. Within the FCC, our sources say, that battle was waged with little success. But many at the FCC (and especially in the enforcement division) are concerned about 2 meter repeaters. They, off the record, compare it to CB, and identify the band as a potential problem. Considering the worldwide use of 144-146 MHz for repeaters instead of the top segment as we have in the US, 2 meters may be a real WARC trouble spot.

1¼ METERS

If the aeronautical pressure on 2 meters isn't enough, 1¼ meters may give you something to think about. Added to the present allocations in the FCC plan is amateur satellite and *mobile* (CB). Taking the specifics, between 220 and 225 MHz, amateur and radio location allocations are retained, but added are satellite and mobile as *primary* services. The FCC is obviously thinking of the Class E CB proposal in making the allocation, but on the other hand, there isn't much enthusiasm in Washington for having hams and CBers share 220. There was a clear implication in off the record conversations with FCC officials that the mobile allocation was intended as a compromise, and not any sign that Class E is about to become reality. The best answer, more than one FCC source told *73*, is to use 220 . . . use it or lose it anyone?

¾ METERS

The ¾ meter band shows little change in the FCC document. 420-435 MHz lists radio location as the primary allocation, with amateur secondary. Between 435 and 438 MHz amateur would be the same, listed as secondary, with 438-450 MHz also unchanged. There are some major changes in Region 1 where 430-435 MHz would put radio location and amateur allocations on an equal basis. Also in Region 1, amateur satellite would be added between 435-438 MHz as a secondary allocation.

3/8 METERS

Another new band in the FCC WARC table is 902-928 MHz. Known as the 3/8 meter band, 900 MHz is set aside primarily for fixed and radio location services, with amateur and mobile newly added as secondary services. Some reports had also listed 935-938 MHz as amateur exclusive, but they were inaccurate.

1215-5925 MHZ

In the bands 1215 and above, the big story is satellite frequencies, lots of 'em. In fact, 85 MHz worth of new allocations are set aside in this range for satellites. Otherwise it's a matter of maintaining the status quo for the most part, with a few exceptions; like increased non-amateur use of 1240-1290 MHz, and the sharing of 3300-3410 MHz with fixed services on a secondary basis. The largest single satellite allocation in this range comes at 5650-5670 MHz, and it's listed on a worldwide basis.

10 GHZ AND ABOVE

Of two new bands proposed in committee above 10 GHz, only one survived the FCC debate — 240-250 GHz. (Another band at 300 GHz had been proposed.) To call 240 a new band requires some background, background that will be helpful in understanding the maze of information FCC staffers, and the commissioners themselves, had to sift through before reaching agreement. The band has been listed by the FCC before as an amateur allocation, but has not appeared on the international tables. Therefore, the FCC recommendations are aimed at international recognition . . . not domestic use alone. The Commission document lists amateur and amateur satellites as secondary allocations, to be shared with radio location, fixed, and mobile as primary users. But at 248 GHz the FCC has included a ±500 MHz wide ISM segment (Industrial-Scientific-Medical) which amateur users will have to work around. A similar situation exists at 165 GHz, where domestically there is some loss of allocation (at least on paper), but internationally it's a gain. But again, to say the 165 GHz band is losing frequency depends on how you look at it, since the range has been included in the FCC allocations table for some time, but left out of the rules (Part 97). As one Commission official put it, "Present action would afford amateurs secondary status in the band 165-170 GHz, but would no longer provide for 152-165 GHz which is presently available in the US . . . however, 152-165 GHz has never been implemented, so it is in essence a domestic loss only on paper . . ."

300 GHZ AND ABOVE

This range is currently unallocated on an international basis, but the FCC would like to see the WARC set it aside for amateur and experimental use, as it has been listed here in the US. Should 300 GHz and above remain off the international frequency tables, FCC planners say it would not disallow domestic use.

Continued

"On balance, ham radio occupies only a small niche in the global scheme of frequency allocations, and our strongest supporters are outnumbered and outgunned by the Third World."

No one event in the next decade is likely to affect the future of amateur radio more than the World Administrative Radio Conference scheduled for Geneva in September, 1979. Delegates from over a hundred nations will gather for 10 weeks to carve up the frequency spectrum and, in the view of government experts, diplomats, and much of amateur radio's own leadership, our hobby may lose a lot more than it gains. On balance, ham radio occupies only a small niche in the global scheme of frequency allocations, and our strongest supporters (the US, Canada, Great Britain, and West Germany) are outnumbered and outgunned by the Third World.

The Third World

If you've read very much about the current situation in the United Nations, you know that the Asian and African nations that make up the Third World now hold the balance of power in the General Assembly. (US Senator Patrick Moynihan could correct your perspective should you doubt that assessment.) In the ITU, the situation has been that way for over a decade! Because each nation at WARC only has one vote, regardless of its amateur population or actual use of the spectrum, the cards stack up much the same way as they do in the UN General Assembly . . . the more affluent industrial nations are at the mercy of the newer countries that hold much of the world's untapped natural resources.

The underdeveloped nations are not tuned into ham radio any more than they are interested in satellite ground stations or CB. Amateur licensing, for many of them, was a function of colonial government . . . now replaced by independence. Most of them would sooner build up point to point HF stations for communications than invest in satellites. At the heart of the problem is a lack of the technical expertise needed to utilize newer forms of communications, communications often pioneered by amateurs. But with amateur populations diminished, or hampered by an unsympathetic government, there is no training ground in the Third World for higher technologies . . . and thus there is little support for amateur radio.

Ham Ambassadors?

One answer to the problem is amateur ambassadors, people who can demonstrate ham radio's usefulness and persuade the developing countries that hams can help their nation grow. It is a fact that economic and technological abilities of nations can be measured in terms of their amateur populations . . . the more hams, the mora advanced the country. The ham ambassador idea probably might have worked better some years ago considering what's happened to American prestige abroad. Government sources in Washington react to the ham ambassador idea by half-seriously suggesting that the ambassadors should carry the passport of some other country, since in much of Africa a US passport starts you off on the wrong foot!

The new alignment of political power in the world must become more to us than newspaper headlines and TV reports, and for the American amateur radio operator, the reality of the situation is about to hit home. Don't expect any major expansions of the ham bands below 30 MHz at WARC '79, and don't look for any relief from foreign broadcasting. Instead, work for a maintenance of the status quo . . . yes, work for it, by debating the issue and replying to the FCC's frequency allocation proposals, and by conducting yourselves like ham ambassadors on the air.

Frank Williams of the FCC's International Conference Staff is one of the most knowledgeable American experts on the 1979 WARC. Williams not only advisad the FCC on its choice of frequencies for the various services, but has worked with dozens of foreign officials responsible for WARC preparations in other countries. Williams warns that individual amateurs, through their conduct on the air, can have great impact on foreign decision makers. He relates the story of a recent visit to 4U1ITU, the International Amateur Radio Club station in Geneva. In the presence of a telecommunications official from an African country, an off-color incident occurred on 20 meter SSB involving an American station. Williams didn't want to elaborate, but he says foreign diplomats are impressionable, and they don't only listen to 20 meters. Those stationed here in the US are the best their government has, and they *are* listening to amateur radio. Our conduct on the air could have more impact than a dozen amateur ambassadors, from what Williams told *73* in a lengthy interview.

Cutting Up the Pie

Aside from the international political situation, the list of services vying for frequency space is long . . . aviation, private microwave, radio relay, AM broadcast, SW broadcast, fixed satellite, citizen's band, private land mobile, amateur, radio astronomy, auxiliary BC, common carrier, domestic land mobile, TV broadcast, maritime mobile, and more. That's 14 against 1 just for the attention of the WARC delegates! But what is the US doing about WARC?

WARC and ARRL

The answer depends on to whom you talk. FCC officials, at the end of intense work sessions which produced the final allocations draft, said they started back in 1972 in cooperation with the White House Office of Telecommunications Policy. The ARRL's involvement is controversial, with the league claiming its contribution started at the outset with a headquarters staffer in on the four member amateur subcommittee of the OTP advisory committee. The ARRL role was purely advisory, and focused almost entirely on the complicated series of committees charged with recommending an allocations table to the FCC. Except for the ARRL's relationship with the IARU, little was done on an international basis. Here at home there has been considerable in-fighting over WARC. In mid-1976, the entire ARRL Foundation Board of Directors resigned in protest after they were denied the right to work either within the League or outside it on WARC preparations. Amateurs who served on ARRL committees expressed deep concern that all wasn't going well, and questions about the use of League appropriations (set aside for frequency allocations work) continue to be stonewalled. *QST* has offered a steady diet of optimism . . . although the November issue provided a first hint of the *real* story, with an editorial entitled, "Will Amateur Radio Exist in 1980?"

In an interview, Dave Sumner K1ZZ of the League's international staff outlined the ARRL's WARC

CARF

The Canadian Amateur Radio Federation (CARF) has reported to the DOC on recommendations for the 1979 WARC conference. The report includes a request that allocations be made for amateur operation below 10 kHz on a shared basis with other services, that 10 kHz be opened between 160 and 200 kHz for amateur use, that 40 meters be expanded up to 7325 kHz, along with 20 meters (expanded up to 14500 kHz), with status quo on 160, 80, 15, and 10 meters. The Canadian proposal also includes some new amateur bands, 29 meters (10100-10400 kHz), and 16 meters (18100-18500 kHz). The CARF document contains strong references against continued sharing with broadcast services on the 80 and 40 meter bands. 6 and 2 meters, 220 and 450 MHz are included, along with 1296, 2300, 3300, 5650 MHz and the 10, and 24 GHz bands . . . along with 48, 71, 240, 165, and 300 GHz and up . . . all for amateur use in the CARF proposal. The DOC, according to informed Washington sources, is expected to release its findings in late February.

CONFERENCES, CONFERENCES, CONFERENCES

The ITU is built on conferences. Conferences to call conferences . . . and then another conference to call yet another conference. As complicated as it is, we can see similarities in other branches of international relations. How many times, for example, did Henry Kissinger do the negotiation shuttle? How many more sessions of SALT will be necessary before the next arms agreement?

Building up to WARC '79, there will be scores of conferences, at the national, regional, and international level. And one of the most critical areas for amateur radio will be the African and Asian conferences, not unlike one held last June in Gaberone, Botswana. It was the first IARU regional conference ever held in Africa.

To begin with, it was an International Amateur Radio Union meeting, and therefore was pro ham radio. But throughout the news accounts of the session there are signs of concern. As H. Walcott-Benjamin EL2BA, the President of Liberia's Radio Amateur Association, put it: "The amateur service is dependent upon the support of national administrations in order to obtain and maintain adequate frequency allocations. This has placed restraints upon the present day operation and future development of amateur radio . . ." Walcott-Benjamin went on to list the constraints: ". . . lack of suitable frequencies capable of supporting communication during the usual day and yearly propagation variations, congestion and continuing interference due to the large and increasing number of amateur stations, and intolerable sharing arrangements with other services with a steady increase in the number of amateur stations expected to reach one million by 1982. The future of amateur radio now stands at the crossroads . . ."

Mr. Walcott-Benjamin's words were not the only indicator of the rough road ahead; *Radio ZS* reported that there had been political discrimination which had prevented some (African) society members from attending the meeting. The South African journal went on to report that the conference showed evidence that there is little understanding of the problems faced by various African amateur radio societies.

It was those same problems that brought the African IARU delegates to Gaberone last June, in hopes of mapping plans to demonstrate amateur radio's usefulness to all of Africa. As *Radio ZS* put it: "Something had to be done to bring the importance of the decisions that would be made at the WARC to the attention of all member societies in Africa and to their various governments, as those decisions would influence the future of the amateur radio service throughout the world . . ."

Among the resolutions adapted at Gaberone was a draft plan aimed at developing amateur radio in Africa . . . specifically in Botswana, Lesotho, Rhodesia, Swaziland, and Zambia. It calls for IARU sponsorship of club stations in each country, improved availability of ham radio equipment, more visitation to the area by other IARU regional representatives, and, of course, another conference be held in early 1978, to solidify the African position prior to a pre-WARC session scheduled for Budapest.

efforts. According to Sumner, ARRL General Manager Dick Baldwin W1RU served as the fourth member of the amateur service committee (the remaining members were all FCC staffers, including Frank Williams, Prose Walker, and Merle Glunt — now an ARRL consultant). The committee draft automatically became the League position, with the emphasis on hammering out differences in committee instead of in public. As Sumner put it, "We felt it was far better to have a united front on the allocations than resort to public debate."

Three new HF bands at 10, 18, and 24 MHz were proposed in the ARRL (and FCC staff) report, but all of them were left out of the final FCC draft. Sumner says headquarters was disappointed by the Commission decision to leave them out, but isn't giving up. "We badly need them," Sumner told *73*, "for two basic reasons — increased propagation needs and the growth in numbers of hams around the world." ARRL, in its reply to the FCC draft, will apparently argue for the new bands in terms the Third World countries will understand. The earthquake last year in Nicaragua will be high on the list, with the argument that access to 10 MHz, for example, would have insured a reliable circuit after 20m had closed. The emergency was handled using 40m, but nighttime conditions made it rough. Sumner admits that if the new bands are allocated, hams will have to live with more sharing arrangements on HF.

Above 10m, the ARRL position was more or less a matter of keeping the status quo. Sumner pointed to two exceptions: the need for more satellite frequencies at UHF and the new 900 MHz band. In the ARRL view, 900 MHz could be a way of keeping CB off 220 MHz. Sumner says the League is constantly in touch with the CB industry, trying to persuade them that 900 MHz would be suitable for Class E CB. "If we can figure a way to convince them they want 900 MHz," says Sumner, "we could hold onto 220 MHz and realize net gain overall."

The Current Box Score

The reality of the WARC situation is best summed up by FCC official Williams, who says, "It's difficult to forecast ... nothing is really known about the other countries ... there are no hard proposals forthcoming from the others ..." Williams adds he's not totally pessimistic, since the world is not completely unresponsive to the amateur service, but he's not especially optimistic either. On ham ambassadors, Williams agrees there has to be some kind of international public relations and healthy debate here at home. Most of all, amateurs must keep informed, he says, and be responsive to the FCC's plea for comments.

The FCC draft is the first made public in the world. Canada is expected to follow suit in February, but aside from those two, most of the 100 nations headed to WARC two years from now have not even started their preparations. A look at the history of previous WARC conferences shows the current lack of preparation to be about normal. And it can be interpreted to mean the trend of previous conferences will continue ... the trend of fewer HF allocations with an

"In mid-1976, the entire ARRL Foundation Board of Directors resigned in protest after they were denied the right to work either within the League or outside it on WARC preparations."

"Most of the 100 nations headed to WARC two years from now have not even started their preparations . . ."

increased emphasis on SW broadcast, UHF, and the range above 10 GHz. The prime exception came in 1947, when the delegates set up the 15 meter amateur band, with sharing arrangements granted international broadcasting. It was not called the 15 meter amateur band, because ham radio was not officially recognized by WARC until 1959, when the conference voted to add the amateur service to the allocations tables.

The FCC Draft

Elsewhere in this *73* Special Report, you will find a detailed breakdown of the FCC draft. In spokesman Williams' opinion, the amateur service came off quite well. He points to the new LF band between 160-190 kHz, downward expansion of 160 meters (although 100 kHz would be lost between 1.9 and 2.0 MHz), an improved SW broadcast situation on 80 meters up to 3.9 MHz (the 3.9-4.0 SW sharing arrangement would continue), an expanded 40, 20, and 15 meters, status quo on 10, 6, and 2 meters, some changes on 220 and 450, and extensive alterations (including a new band) above 900 MHz. A theme of the document is increased emphasis on satellite communications, with the lowest downlink frequency coming in at 6.950 MHz (the bottom of the proposal's new 40 meter allocation). Williams attributes the movement towards more satellite frequencies to amateur representation on the committees that drew up the original requests used to formulate the FCC draft, as well as the OSCAR program.

Between the Lines

Two issues remain unresolved by the FCC draft — 220 MHz CB and strong pressure from the aeronautical services for 146-148 MHz. The FCC table leaves, as primary allocations, mobile services in the 220 MHz band. FCC spokesman Williams echoes the sentiments of several commissioners, who've said publicly, "We may never make that decision." The FCC may never make *its* move, but the WARC will probably include the mobile allocation, setting the stage for future domestic debate. The question of aeronautical use of 146-148 MHz will apparently lie with the WARC, although pressure from within the US government was resisted at the FCC level. (One problem with the segment is the use of 144-146 in many other countries for repeater use, with the US actually in the minority in its repeater allocation at the top end of the 2 meter band.)

What's Next?

After the FCC comments period expires, the finishing touches will be put onto the draft, and it will become the official US position for WARC '79. Since it is the first made public, the FCC allocations are likely to become a platform for debate around the world. It may actually end up as a strong weapon in the hands of the Third World, which could be spurred into action by opposition to the US proposals. If nothing else, the FCC allocations table can be expected to stir debate, and the WARC story will begin to take on a more international flavor. But in the final analysis, only time and the complex web of international relations that links blocs of countries together will tell what WARC '79 really holds for amateur radio.

EXCERPTS FROM THE FCC WARC DRAFT

Amateur Service

The Amateur SWG (Service Working Group — advisory committees who proposed individual allocations for each service to the FCC) requested exclusive worldwide allocations between 160 and 190 kHz, 1715 and 2000 kHz, and 3500 and 4000 kHz; we can only partially accommodate these requests because of the requirements of other services operating in this long established portion of the spectrum. We are proposing to add the Amateur Service in the band 160-190 kHz on an exclusive basis. Exclusive allocations are also proposed between 1725 and 1900 kHz in Regions 1 and 3 and between 1750 and 1900 kHz in Region 2; we are additionally proposing an exclusive worldwide allocation in the band 3500-3900 kHz along with a continuation of the present allocations between 3900-4000 kHz.

The Amateur Service Working Group requested expansion of the Amateur allocations at 7, 14 and 21 MHz. Additionally, the SWG requested new allocations at 10, 18, and 24 MHz for the Amateur services. In both cases, wholesale relocation and reduction of existing Fixed services allocations would be required, with other services being affected to a lesser degree. In the presence of requests from other services whose needs we deem to be more pressing, we have not been able to fulfill the total requests of the Amateur SWG. We are, however, proposing some expansion at 7, 14, and 21 MHz, as set forth in the proposed table.

The Amateur Radio SWG requested that present allocations between 27.5 and 1215 MHz be maintained, that provision be made for Amateur Satellite operations in the band 220-223 MHz, and that Amateur operations be permitted in the band 902-928 MHz. At this time, no conflicts appear to the first two allocations requests. As the table shows, we propose to provide a primary allocation for Amateur Satellite at 220-225 MHz. Amateur operations in the band 902-928 MHz for Region 2 are proposed as a secondary service.

The Amateur Radio SWG requested that the present allocation at 1215-1300, 2300-2450, 3300-3500, 5650-5925 and 10000-10500 MHz be maintained. They stated that the relatively wide, but shared, allocations are necessary to permit experiments with wide band emissions and to prevent interference to/from users in adjacent bands. They also requested that a small segment in each of these bands be allocated to the Amateur Satellite Service in order to permit experimentation with space communication techniques. They pointed out that a 2304.1 MHz beacon was built into the OSCAR 7 satellite but could not be utilized for lack of an international allocation.

The Amateur SWG requested that the present allocations at 24-24.05 GHz and 24.05-24.25 GHz be retained and that the domestic allocations specified in Docket 19973 at 48-50, 71-76, 165-170, 240-250 and above 300 GHz be implemented internationally, because of the intensive interchange of ideas which takes place between amateurs in different countries. As our table shows, we are proposing no change to the existing allocations and also proposing additional allocations at 71-76, 165-170, and 240-250 GHz as in the Domestic Table. However, we are reserving the band at 48-50 GHz for Aeronautical and Maritime services.

Broadcast Services

The AM Spectrum SWG requested that the band 535-1605 kHz be continued as allocated to the Broadcasting Service on an exclusive basis, and that neighboring frequencies between 525-535 kHz and 1605-1805 kHz be also allocated in certain regions. As the proposed table reflects, we have added Broadcasting on a primary basis to Regions 2 and 3 at 525-535 kHz; we have continued the exclusive allocation at 535-1605 kHz; and we have added Broadcasting at 1605-1615 kHz on a shared primary basis in Region 2. While 1615-1805 kHz has not been included in the table at this time, additional spectrum space in this band for AM Broadcasting will continue to be considered in view of the potential heavy demand for new stations by commercial, non-commercial, and minority group applicants and in view of the direct public interest benefits of this service. The use of reduced

Any item may be reprinted, as long as proper credit is given.

At press time the news wasn't good for the Bicentennial Relay project. Despite weeks of trying, an appointment still had not been made to see President-Elect Jimmy Carter and deliver 45 messages of congratulations sent via amateur radio (five governors formally refused to participate). Carter was apparently too busy choosing a cabinet to accept the messages, although he did find time to, among other things, reply personally to a group of New Hampshire ski operators who were worried about competition from state-owned ski areas who'd requested federal aid. *The New York Times* reported Carter was getting out of touch, becoming isolated from the people. Meanwhile, Bill Miller K4MM, the prime amateur protagonist trying to get the appointment, had nothing new to report. "We're doing the best we can," he told *73*, but as time slipped by, it was beginning to look like ham radio occupied a lowly place on the new President's priorities list.

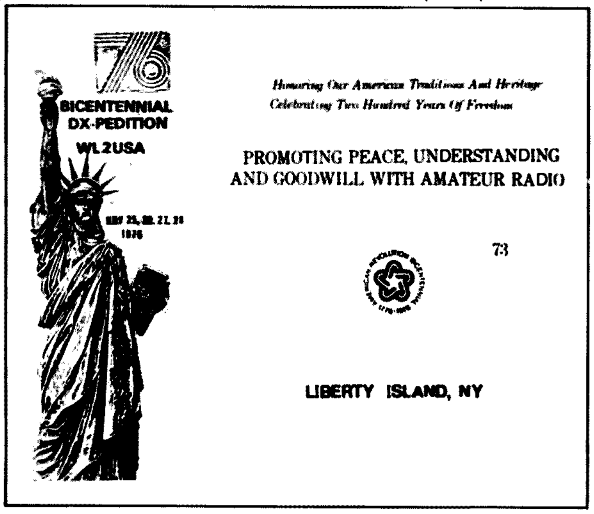
The relay was the idea of Eric Shalkhauser W9CI, a Bradley University professor who participated in the first Presidential Relay held in 1916. (Shalkhauser's series on the history of ham radio will begin in *73* with our next issue.) ARRL officials, QCWA officers, Miller, and Shalkhauser were to participate in the delivery, but unless the new President personally accepted the messages, ARRL officials reportedly would not be in attendance.

Messages from the governors, and the Mayor of the District of Columbia, were ready for delivery within two weeks of election day. The traffic was handled via OSCAR, RTTY, CW, SSTV, and SSB, with several governors offering their congratulations personally via 2m HTs. That attracted a lot of local press attention, but at press time the bottom line on the national level remained political red tape 1, ham radio 0.

The FCC continues its crackdown on illegal CB activity. Raids at Syracuse NY, Houston TX, Lima OH, and Columbus GA are among the latest. FCC Enforcement Chief Richard Smith told *73* the same pattern is coninuing, with amateur equipment and over-powered CB units confiscated, and users facing stiff fines. Indications are the FCC won't have any measure on how effective the program has been until summer 1977, but a survey conducted last year showed out-of-band operations on the increase while identification and license applications for legal CB were up. As the crackdown continues, FCC staffers in Washington are pondering plans to shut down the outlaws. A three point proposal was due to be submitted by year's end with a rule-making notice to follow. Banning the manufacture of all linear amplifiers capable of 11 meters, requiring dealers to see proof of license before selling gear, and type certification of all equipment were the prime recommendations. Amateur gear *would* be affected, although hams would not be stopped from modifying commercial gear or home brewing their own. Existing gear would be exempt, and manufacturers would be given a grace period to redesign their product lines.

The manufacturers (as you can expect) don't think too much of the idea. Robert Levine of Dentron told *73* he'd call about 15 manufacturers together at the SAROC Hamfest in Las Vegas in a bid to block any possible ban. "Illegal use of linears is a threat to ham radio as a hobby and to the livelihood of the manufacturers who want their equipment used legally," said Levine, who emphasized only major manufacturers would be invited to the SAROC session. (See Guest Editorial this issue.)

The ever-changing nature of the CB market has very nearly sunk a line of amateur products. Throughout the fall, persistent rumors in the industry hinted at the fact that Hy-Gain Electronics Corporation of Lincoln NE was in trouble because of a multi-million dollar commitment to 23 channel CB. With the emphasis on the CB market, amateur products were rumored to be in the process of being phased out.



Hy-Gain Amateur Products Manager Kip Kitterer admitted that with the emphasis being placed on CB, amateur products were placed in limbo with little in the way of advertising or development money being made available. However, early in December, a decision was made to remedy the situation. Hy-Gain was split into two completely independent companies. Hy-Gain de Puerto Rico, headquartered in Coral Gables FL, now has complete responsibility for all CB and scanners. Hy-Gain Electronics took over the Lincoln plant and handles the entire amateur product line of antennas, a new hand-held 2 meter rig, and the 3750 transceiver. All marine and commercial land mobile equipment will also be manufactured at the plant.

Saying the company is now in the best position ever, Kitterer expects to broaden the product line. Four new VHF yagi antennas will shortly be available and the company will update and redesign its entire antenna line.

Despite the fact he's being used for false advertising and nondelivery of ordered items, Irael Treger W9IVJ of Trigger Electronics is still sending out catalogs, according to the Illinois Attorney General's Office. AG's spokesman John McPhee says he's pressing for a court injunction to stop the mailings, but is running into trouble finding witnesses. According to McPhee, most witnesses have been willing to sign affidavits, but are unable to appear in court. At press time McPhee was seeking the aid of local Chicago groups to find area people who'd dealt with Trigger. The mailings, meanwhile, have reportedly shifted in emphasis from newly licensed hams . . . to CBers!

WL2USA, the Thanksgiving weekend bicentennial operation at the Statue of Liberty, cleared 1200 contacts, according to organizer WA2NVG. Unfortunately, there weren't enough operators to cover all bands, as had been hoped for, and the station was only able to operate on 20 meters. Despite the problems, it's reported the project was a success . . . and quite educational in terms of dealing with government red tape and Murphy.

Don't look for many changes on the ARRL Board of Directors. After this past year's elections, five Directors were reelected without contest, along with two Vice Directors. In five other Director and Vice Director races, it was incumbents all the way, although some elections were closer than expected. In New England, for example, Vice Director John Lindholm W1DGL won by less than a hundred votes. The only surprises were the election of Don Miller W9NTP as Central Division Director (note this is not the Don Miller of Minerva Reef, etc.), and in the Roanoke Division, incumbent Vice Director Donald Morris W8JM was beaten by Gay Milius W4UG. *West Coast DX Bulletin.*

In what is believed to be first action of its type, a group of Southern California amateurs has voted to expel a member from its ranks. During a special meeting early in December, the Community Amateur Radio Service of North Hollywood voted in secret ballot to expel a Los Angeles member for reasons that he "has not demonstrated the level of maturity required for participation in a program serving a law enforcement agency . . . and has knowingly used the air for his own amusement in such a way as to lessen the pleasure of others."

It was alleged that the expelled member had refused to remain on his assigned post when directed by net control, saying that he would rather go home. A recording was also presented showing that he had interfered with traffic handling during a declared emergency.

Members further said that the ham's primary form of self-gratification was his habit of harassing other operators who were operating legally. They cited cases of his breaking into QSOs to announce that he had nothing to say but had a "right" to interrupt.

Since the Community Amateur Radio Service is affiliated with the Los Angeles Police Department, members said his actions have brought shame or discredit to the group. The ham was expelled from the organization and his actions outside the organization condemned as being "a detriment to the amateur service." Adding salt to the wound, the membership further declared that he cannot be considered for readmission to the organization until he "has demonstrated that he has become a mature and responsible member of the amateur community."

The increasing numbers of people entering the amateur radio ranks has created a great increase in the amount of "questionable" practices, especially on repeaters. It appears that the action of the Community Amateur Radio Service, although the first, will probably not be the last attempt to clean up the airwaves.

The ARRL may be having some second thoughts about lobbying in Washington. According to a report in the *West Coast DX Bulletin*, the loss of tax exempt status by the National Rifle Association and Sierra Club was attributed to lobbying expenditures in excess of Federal limits. At issue is section 501 (c) of the IRS Code, which most interpretations say, allows 5% lobbying expenditures out of an organization's total budget. The ARRL board is reportedly considering

a major lobbying campaign anyway, with some directors saying the dollars lost if tax exempt status was revoked may be less important than fighting legislative and administrative actions affecting amateur radio. The stakes, however, are high . . . because some of the major advantages of AARL's tax exempt status are the major reductions in mailing costs for *QST* and in property taxes on the Newington CT headquarters.

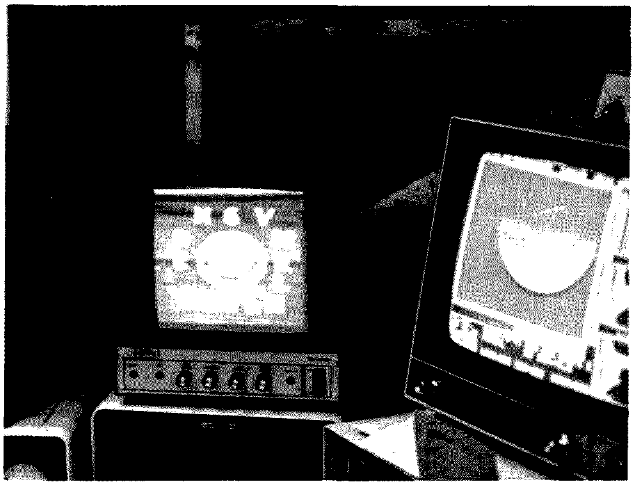
Award-winning humorist, radio talk show host, TV broadcaster, film writer, and amateur extraordinaire Jean Shepherd K2ORS will soon be writing for *73*. Shep's latest accomplishments include a monthly column in *Car and Driver*, the TV play "Phantom of the Open Hearth" (recently broadcast nationally on PBS), and his long-running PBS series "Jean Shepherd's America." Several times the winner of *Playboy* magazine's humor award, Shepherd can be expected to produce some interesting material on ham radio, as anyone who's witnessed his hamfest talks can tell you. Shepherd's latest novel, "The Secret Mission of the Blue Assed Buzzard," about his Army career, is due this month. As *the New York Times* put it in a recent article on Shep, "He is a tribal storyteller, trying to explain us to us."

The bureaucratic red tape which permeates all levels of government has not failed to reach the FCC. In one recent incident, an Illinois amateur was threatened with administrative action against his license after a mix-up within the postal system.

John Maenpaa WB9JOJ of Dundee IL became entangled in the mess a year ago while conducting Novice classes. Five Novice exams were lost in the mail between Gettysburg and Dundee. All students subsequently received their licenses when another set of tests was sent, but that was not the end of problems. The FCC insisted that the tests that were never received be returned. Maenpaa told *73* that the FCC refused to acknowledge his reply and threatened action against his license.

At last report, the situation was still up in the air. Maenpaa said he has spent hundreds of hours teaching Novice classes and is now reconsidering his position, saying he only stands to lose his license if he continues.

Amateur licenses are really up, according to FCC spokesman Dick Everett. Everett told *73* the increase is "dramatic" . . . with a completely reorganized processing center at Gettysburg turning out exams and licenses in 8 to 10 days on the average. Two years ago ham licenses were slipping by nearly 300 a month. Now the total is up over 280 thousand . . . and climbing. Don't forget to use Post Office Box 1020, Gettysburg, when filing exams, renewals, and address changes . . . it's bound to speed things up.



The latest news from the Jet Propulsion Laboratory in Pasadena CA is that the Mariner pictures transmitted by N6V are now available on cassette. And club station W6VIO is still available for schedules to SSTV the Mars pictures, with special interest in providing the material to school groups. N6V's license expired in mid-November, according to club spokesman Jim Lumsden WA6MYJ. Jim tells *73* JPL is now working on next year's launch of M-J-S, Mars-Jupiter-Saturn . . . a fly-by flight. It is possible the vehicle will reach Uranus as well, with SSTV pictures and another special event call in the works. If you want the 60 minute SSTV cassette of the Mariner pictures, including the famous first photos from both the orbiter and Mars lander, send $3.75 to W6VIO, JPL, 4800 Oak Grove Rd, Pasadena CA 91103, attention R. Piety M/S 158-205. Schedules can be arranged by writing Jim Lumsden at the same address, M/S 233-103.

The United Nations inaugurated their new amateur radio station, K2UN, on October 21, 1976, which was completely equipped by Yaesu Electronics Corporation of Paramount CA. Impressive dedication ceremonies included worldwide contacts with amateurs in other countries.

Mr. Mohamed Mili, Secretary General of the International Telecommunication Union, is shown at the operating console with Mr. Max C. de Henseler HB9RS, President of the club's station, looking on. Mr. Harry Dannals W2TUK, President of the American Radio Relay League, Mr. Stan Zak K2SJO, Director of the Hudson Division of the ARRL, and U.N. dignitaries were on hand for the dedication.

The purpose of the station is to foster good will among the people of all nations in the world through friendly radio contacts in a hobby they share. The Yaesu Electronics Corporation provided three complete stations for U.N. use. Yaesu equipment is also in use at the headquarters of the International Telecommunication Union station, 4U1TU, in Geneva, Switzerland.

Antenna Specialists is offering a free antenna range calculator. A =10 SASE to 12435 Euclid Ave., Cleveland OH 44106, is all it takes.

The Long Island Mobile Amateur Radio Club (LIMARC) has taken to the broadcast airwaves with ham PR. WA2HYS, WA2DHF, and WN2DRO are producing a weekly show on WBAU-FM. The idea is to portray ham radio in unique ways, and it's apparently working. The station has signed the LIMARC effort for another 13 weeks, and several groups are considering use of the material on a national basis. If you're in the NYC area, tune in on Friday nights at 7:45 on WBAU-FM, 90.3 MHz.

A $75,000 prototype HF transceiver was stolen in the Ottawa, Canada area last summer, and the authorities apparently still have no leads. The rig was in Canada for a demonstration by the US Army. Although it is not classified, it does represent an extremely high level of miniaturization technology, according to a report in the *Ottawa Citizen*. Lifted from a National Defense station wagon parked outside a local motel, the transceiver is capable of operating on both the amateur and CB bands. *The Canadian Amateur*, Kingston, Ontario.

An amateur from Jacksonville FL has received the first single band Worked All States award for RTTY. The award, issued to "Big Al" Mitchell WA4HLP, was only the 18th WAS ever earned for the mode.

Mitchell used 20 meters and ran less than 100 Watts. At the time of the award, he had been a General for only four months, beginning his ham career at the age of sixty.

Faster and more accurate location of downed airplanes and illegal transmitters is the aim of a California group headed by Hartley Postlethwaite IV WB6COW. The Happy Flyers (Hams And Pilots Piloting And Yakking) was originally formed to provide a group of qualified volunteers to be available during national emergencies and for public service. Since its formation, the group has branched out into ten "squadrons," primarily situated in the west.

Postlethwaite proposes to integrate the national repeater system into a network for locating downed aircraft. As a plus, the same system would make for easier detection of illegal transmitters and jammers. The Federal Aviation Agency requires all aircraft, from the smallest homebuilt to the 747, to carry an Emergency Locator Transmitter (ELT), which is automatically activated when a certain G-force is exceeded, as when a plane crashes. The ELTs transmit on 121.5 MHz, the international aircraft distress frequency. When the transmissions are picked up by any of the FAA centers located across the country, automatic alarms are set off. Unfortunately, many planes go down in remote or mountainous areas where the low power transmissions from the ELTs are almost useless. It may be many hours or days before the ELT transmissions are detected, often by a passing airliner that is flying too high to pinpoint any location.

Postlethwaite is proposing that all amateur repeaters be equipped with a 121.5 MHz monitor which would activate an alarm on the repeater if it received an ELT transmission for more than six minutes. (The six

TEN-TEC TRITON IV HF TRANSCEIVER

Ever since 2 meters, I've been looking for an HF rig I could take with me just like my HT and use mobile (where my 71 MGB-GT makes space a vanishing commodity). Those of you driving big cars may have bigger gas bills, but you've got me beat to heck on going mobile.

So, let's look at my situation, and consider what's available for HF portable/mobile. The list of self-contained mobile rigs isn't very long, not if I'm going to get into 20 SSB during the day, and 75 SSB at night. For one thing, I've got to have some power, and the ability to quickly change bands, preferably while in motion.

Enter the Triton IV. It weighs less than 12 pounds, measures just over a foot wide and four inches high by ten inches deep. The Triton IV is a no tune solid state, 200 Watt input, CW-SSB transceiver built at Sevierville, Tennessee.

It is the latest in a line of innovative transceivers made by Ten-Tec. Argonauts made Ten-Tec famous, and helped popularize QRP rag chewing, DXing, and just plain QRP hamming. Ten-Tec radios have attracted an intensely loyal following, and Argonauts have taken many a convert from the kW crowd.

The guy who got me interested in the Triton IV was Alan WA1MSK. He'd been regularly checking into 75 meter QSOs mobile with S9 signals, and there were often fixed stations having a much harder time. After hearing several of Alan's mountaintopping expeditions with Paul WA1VEI, the jealousy bug mingled with the mobile bug, and it was all over; I had to taste a Triton IV.

The Triton IV immediately gives away its lineage, because the Ten-Tec designers borrowed a lot of ideas from the Argonaut. One idea they left behind, though, was QRP: The Triton IV drove my SB-200 amplifier to full input with ease, and (using only the Ten-Tec and dipoles) DX, local QSOs, and nighttime schedules were handled nicely.

Mobiling proved to be most interesting . . . my last mobile rig was an HW-32 . . . and mobiling with the Triton IV brought back fond memories. The MGB's legendary ignition noise (second only to the infamous 280Z of W2NSD) was fooled by the Triton IV. Either I've discovered a new way of suppressing ignition noise, or Ten-Tec knows how to fool it (but I haven't cured the 2m rig, so it must be the Triton IV). An accessory noise blanker is also available.

The approaching Christmas holidays and Old Man Winter prevented a jaunt up Mount Monadnock or some other nearby peak, so my 12 V battery-powered DXpedition was scratched from the test. Instead I took the rig on holiday, threw up a wire, and proceeded to have a blast operating battery portable. All I packed was the Triton IV, mike, key, and dipole antenna . . . and it all fit into a briefcase with room to spare! (Murphy helped me forget a 12 V battery, so I had to buy one at a local hardware store.)

The best thing about the Triton IV is honestly hard to pick. I know you're probably saying that's a put-on . . . but it is not. The Triton IV is about the most flexible transceiver I've ever seen. I really like its *true* break-in CW . . . just like VOX, but more. You can hear in between words – even characters. CQ QSOs are suddenly spontaneous, less stereotyped. The system really gives you an advantage in DXing, because you can slip your call in fast. (The transmit-receive switching is instant, and your QSO rate in contests is bound to improve.)

Tuning the Triton IV is easy . . . switch bands and turn the carrier on. Peak the drive with the ALC LED, tweak the receiver to resonance, and away you go. (That's unless Murphy got your antenna!)

All no-tune rf amplifiers require a proper load, so unless your antenna is properly matched, no final (transistor *or* tube) is going to work efficiently. The Triton IV's transmitter is rugged; using Ten-Tec's ac power supply, it shut down automatically when faced with a bad match, but ran without strain into a good one. A front panel swr indicator on transmit doubles as an honest S-meter on receive.

Ten-Tec has made a lot of these Tritons and Argonauts. The hams there are dedicated and proud. Their owner's manual says a lot more about company philosophy than any other manuals I've read lately. "There are sufficient Tritons now in the field to indicate to us that there are several rather serious information gaps in . . . the case of new technology such as solid state no-tune rf amplifiers. The main concern appears to be a matter of fundamental technical knowledge regarding swr, efficiency, and protective circuitry such as LAC and power supply overload protection." Ten-Tec goes on to list 10 points to keep in mind when using the Triton IV; most concern antennas and swr and the thrust is one of ham radio's cardinal rules: the better the antenna, the better the signal.

That company philosophy I mentioned earlier comes through in Ten-Tec's warranty statement as well. "The warranty is *not* voided for attempted repairs to defective units, the installation of additional switches, etc., when there is no change in the basic circuits." The final transistors are warrantied for 5 years, pro rata. A set of lab measurements came with our Triton IV test unit. On typical ham shack test equipment (power meter and monitor scope), the power output specs matched within 5 Watts, carrier suppression appeared better than reported, and, as the receiver specs indicated, no unwanted signals could be heard. The Triton IV was fun to use . . . a pulsed crystal calibrator which attenuates incoming signals (nice), front panel ALC control, *full* break-in CW, sidetone monitor, two CW bandwidths with an optional filter, an 8 pole crystal filter, offset tuning, selectable sideband, excellent stability, 200 W input, and enough accessory connections on the back panel to run an amplifier and remote receiver (including muting). There's power for VHF-UHF converters (OSCAR anyone?), digital frequency readout (pre-wired for Ten-Tec's own unit), and a half dozen other Ten-Tec accessories, including a 160m converter and remote VFO.

In short, the Triton IV does what Ten-Tec says it will. It's an attractive, reliable, flexible, all-transistor HF transceiver . . . and it's got a lot of class. Ten-Tec Triton IV, price class $699.00, ac power supply $99. *Ten-Tec Inc., Sevierville TN.*

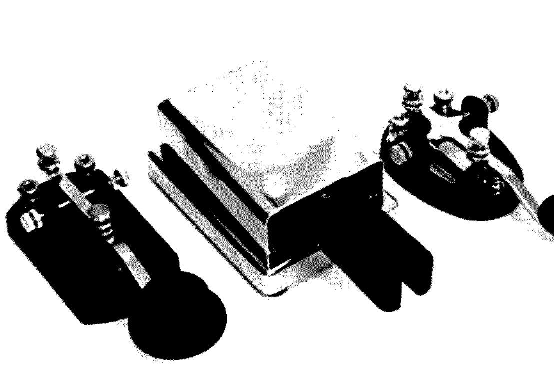
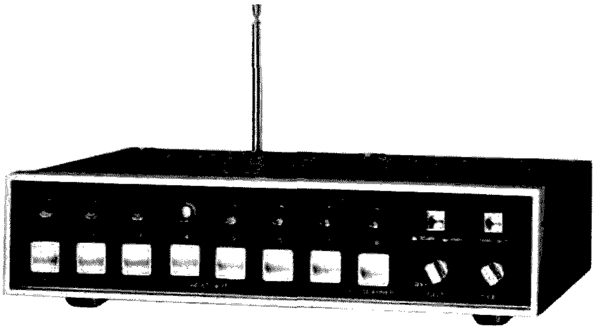
NYE-VIKING KEYS

CW is not dead. In fact, with the ever-increasing number of Novices entering the amateur ranks, and the recent extension of Novice privileges to Technicians, CW is enjoying an increase in popularity not seen since the day of the spark transmitter. The choice of keys is as wide as the quality of fists. They range from $1.49 mass merchandise varieties to high priced gold presentation models. For both the newcomer and the experienced brass pounder, picking the right key can be a frustrating job.

Much has been written about the pros and cons of straight keys, bugs, squeeze keys, electronic keyers, etc. Most hams, however, would probably agree that the old favorite is the standard straight key. One of the largest selections of straight keys available comes from the William M. Nye Company of Bellevue, Washington. In a time well known for products that are low in quality and high in price, the Nye-Viking line of CW keys and accessories stand out as an exception. They have eight separate straight keys ranging in price from $6.65 for the standard black and chrome to $13.50 for the top of the line heavy duty with a shorting switch. Their keys are





mounted on die cast bases and are available with brass, chrome, or nickel-plated hardware.

Both the beginner and old-timer will find the Viking keys a joy to use. Adjustment is easy and they have the solid feel that's necessary for serious CW operating. In fact, after a three hour session at the transceiver working the Novice bands, there was no evidence of the dreaded "glass arm."

Although the straight keys are the standard of the Nye-Viking line, they also make what are called the "Super Squeeze Keys." While they can easily be utilized as a sideswiper, the Viking squeeze keys are designed for use with an automatic keyer. For the sake of nostalgia, Nye also offers a telegraph sounder for $28.00. Also in the Nye line are two matchboxes, retailing for $212 and $355.

Nye also told me that a new random wire tuner will be available about the time this article goes to press. It will handle full legal power from 2-50 MHz and will retail for below $300. Completing the Nye line is a heavy-duty low pass filter which sells for $19.95, and two phone patches, with or without built-in speakers. They retail for $44.50 and $36.50.

Some readers will recognize the Viking keys and matchboxes. The line was originally manufactured by the E. F. Johnson Company. In 1973, they decided to phase out their amateur products line and the William M. Nye Company purchased the design and manufacturing rights. Since that time, they've improved and expanded the line, adding the squeeze key to the original products.

The Nye Company is a small organization with a high quality, carefully built product line which should give the owners a lifetime of dependable service. In these days of mass production, that's a pleasure to see. *Wm. M. Nye Company, Incorporated, 1614-130 NE, Bellevue WA 98005.*

MODEL TTLP LOGIC PROBE

Sylvanhills Laboratory's TTLP logic probe was designed to be used in testing logic levels that are either static or asynchronous. Since most counters, flip-flops, etc., change states on the trailing edge of the input waveform, the unit was simply designed to capture the negative-going pulse. And it uses a seven-segment LED display to tell you if the voltage is a logical one or a logical zero. If the voltage is 0 to .8, the display reads "0"; if the voltage is 2.2 to 5, the display reads "1". Simple as that!

The connections are even easier . . . connect the black lead to the ground of the system under test, connect the green lead to a 5 volt supply point, and you're all set. If you have power, a decimal point is displayed. Touching the probe to the terminal under test then gives you a logical 1 or 0. (Voltages between .8 and 2.2 give a blank display.) All in all, it's a simple and easy to use logic probe for the hobbyist or TTL designer. Options include an overvoltage protection circuit (should the probe be touched to a voltage as high as +24 V for several seconds), and a model TTLP-2 (with memory). The basic TTLP-1 is $19.95; the TTLP-2 is $24.95, and the "overvoltage protection" is $.75. By the way, this is a fully assembled probe, not a kit. For further information contact *Sylvanhills Laboratory, Inc., #1 Sylvanway, Box 239, Strafford MO 65757, 417-736-2664.*

NEW SCANNERS FROM HEATH

Heath Company has introduced two new 8 channel VHF Scanning Monitors. The GR-1131 Hi Band Scanner and the MR-1134 Marine Band Scanner are designed to provide hours of exciting and informative listening.

The GR-1131 Hi Band Scanner monitors any combination of 8 channels in the "emergency services" band (146-174 MHz), automatically tunes in on police, fire, ambulance, U.S. Government weather broadcasts, and more. The GR-1131 scans each channel, stopping on any signal, and resumes scanning after the transmission. A priority channel feature checks the channel you're most interested in every 4 seconds and automatically switches to it if there is activity on the channel. Other features include channel lockout buttons, lighted channel indicators, automatic or manual channel selection, and a 4 pole crystal filter for good selectivity. For crowded signal areas, an optional 8 pole filter is available. It also features a built-in telescoping antenna and provision for an external antenna. Operates on either ac or 12 V dc. The GR-1131 is perfect for volunteer firemen, civil defense personnel, or just for listening.

The MR-1134 Marine Band Scanner is a valuable accessory for boat owners or anyone who lives near a harbor or lake. It monitors any 8 frequencies in the 156-163 MHz marine band, and picks up weather reports, marine emergency channels, harbor instructions, ship to shore and ship to ship communications, and more. The MR-1134 has the same deluxe features as the GR-1131, and includes a rugged splash resistant case ideal for marine use.

The two scanners are mail order priced at $89.95 and $99.95 respectively. *Heath Company, Benton Harbor MI 49022.*

NEW TWO-PALLET ALUMINUM TOOL CASE

Jensen Tools and Alloys has introduced a new tool case for the field engineer or technician who frequently travels by air. Constructed of jet smooth, seam free molded aluminum, the case weighs only eight pounds yet is strong enough to stand on. It is designed to resist abuse and take the hardest knocks of airline baggage handling equipment.

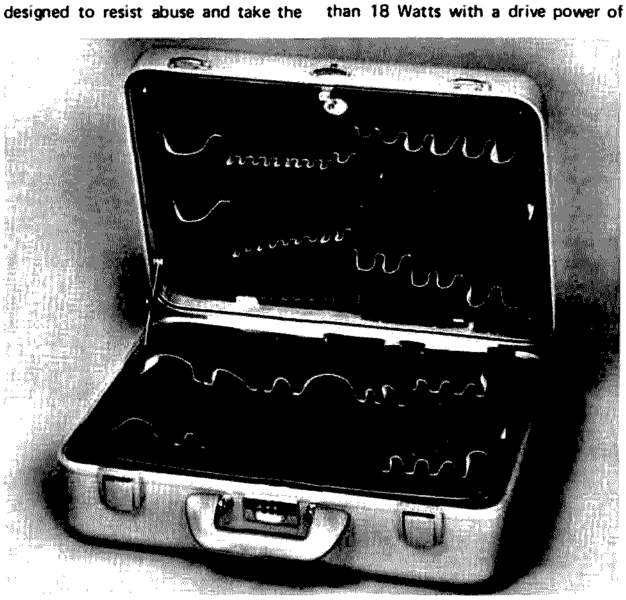
Among its features are a full length piano hinge across the back, a tongue and groove closure with a live rubber gasket to seal out moisture, dust and dirt, a document pouch inside the cover, and a keyless combination lock.

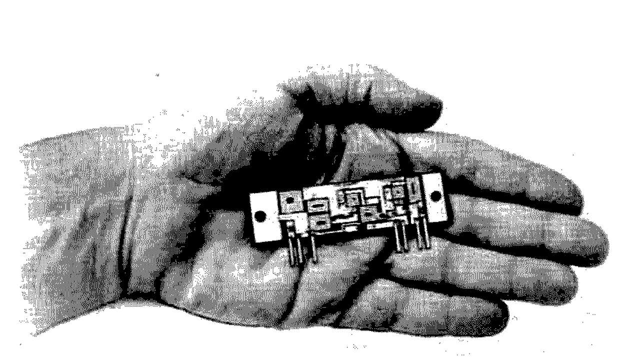
The bale-type latches are chrome plated and the matching handle is made of tough Tenite. The two removable pallets hold a full complement of tools and the pockets are both riveted and stitched for strength. Inside dimensions of the case are 17" x 12½" x 5".

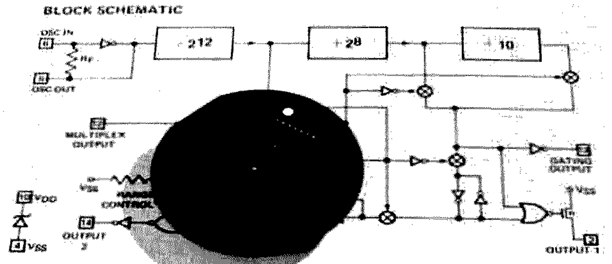
The case sells for $145.00 with quantity prices substantially lower. To order, or for a free catalog describing other tool cases and tool kits, write: *Jensen Tools and Alloys, 4117 N. 44th Street, Phoenix AZ 85018 or call (602) 959-2210.*

AMPEREX VHF & HF AMPLIFIER MODULES

Amperex Electronic Corporation has a new line of VHF and HF amplifier modules containing internal matching networks for broadband applications. Two units, designated BGY32 and BGY36, operate at 68 to 88 MHz and 148 to 174 MHz respectively. Each module will deliver better than 18 Watts with a drive power of







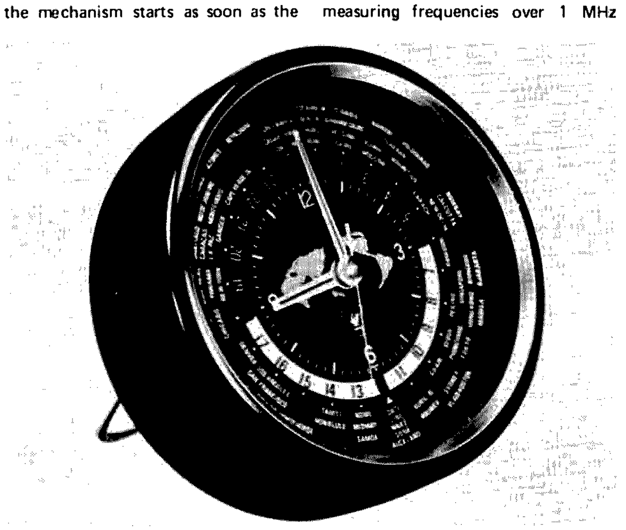
less than 150 mW at a supply voltage of 12.5 volts. The input impedance and output impedance are matched to 50 Ohms with no instability into a VSWR of up to 3:1 over all phase angles.

Both the BGY32 and BGY36 will not be damaged with VSWRs of 50:1 through all phase angles at heat sink temperatures of up to 70° C.

The price for both modules is $52.50 in quantities of 1-9, and $44.50 in quantities of 10-99. Delivery of sample quantities from stock with production units available in 90 days. *Amperex Electronic Corporation, Hicksville NY 11802. (516) 931-6200.*

YAESU 24 HOUR CLOCK

A new precision clock which tells time anywhere in the world at a glance has been announced by Yaesu Electronics Corporation. The time in any principal city or time zone can be simultaneously coordinated with local time on a 24 hour basis. After the initial setting, as the clock runs, a Time Zone Hour Disc advances automatically, showing correct time all over the world without further adjustment. The clock is especially designed to withstand shock, and may be hung on a wall or placed on its desk mount. The clock will run an entire year on a single 1.5 volt flashlight battery and the mechanism starts as soon as the battery is inserted. It measures six inches in diameter by two and one half inches deep. An excellent item for the business office, ham radio operator, short wave listener, boat owners and others who want an accurate, dependable clock. Priced at $30.00, it is available at all authorized Yaesu dealers in the United States. *Yaesu Electronics Corporation, PO Box 498, 15954 Downey Avenue, Paramount CA 90723.*



INTERSIL FREQUENCY COUNTER TIMEBASE

Intersil has broadened its line of timing microcircuits through the addition of the ICM7207A, a new frequency counter timebase. Used together with a 5.24288 MHz crystal and a 7 digit unit counter such as Intersil's ICM7208, the new circuit becomes a complete timer-frequency counter.

The new circuit is pin for pin compatible with Intersil's ICM7207; however, it has 0.1 and 1 second count enable window output.

When used with the ICM7208, the circuit's four outputs provide the gating signals for the count window, store function, reset function, and multiplex frequency reference. The 1 second count enable makes it possible to obtain 7 significant digits when measuring frequencies over 1 MHz with the least significant digit reading in Hz.

The ICM7207A will take crystals from 1 to 10 MHz, providing outputs at crystal frequency, and at $\div 2^{12}$, $\div 2^{20}$, or $\div(2^{20} \times 10)$ divider stages.

The new circuit has a stable HF oscillator, and it dissipates less than 5 mW at 5 volts. According to Intersil, the new circuit will be quite useful for applications requiring a system timebase, oscilloscope calibration generator, marker generator strobe, or frequency counter controller. The circuit is packaged in a 14 pin DIP. Dice are also available. Pricing is as follows: ICM7207AIPD 1-24 $6.60, 25-99 $5.35, 100-999 $4.40. Dice pricing is as follows: ICM7207A/D 25-99 $4.20, 100-999 $3.50. *Intersil, 10900 North Tantau Ave., Cupertino CA 95014.*

LARSEN KULROD™ MOBILE ANTENNA

Not unlike the proverbial search for an honest man, my search for the best mobile antenna has been fraught with peril. I've been led through radio stores, electronics catalogs, and dark alleys. I've tried gutter mounts that gut the finish, trunk lip mounts that creep off, and "super" magnetic mounts that fall off in a five mile per hour breeze. Couple those frustrations with a complete inability to obtain a swr below 2:1 and you have the stuff of which nightmares are made.

Finally, I can stay home nights . . . I can sleep peacefully and dream of rare DX. All because I've found it – the most nearly perfect mobile antenna that I can expect in this life. It's called the Larsen Kulrod™, made by Larsen Electronics, Incorporated of Vancouver WA. As far as I can see, Larsen manufactures and sells the most complete line of mobile VHF/UHF antennas available. It takes a few minutes to figure out the massive Larsen catalog, with its proliferation of mounts and whips, but no matter what type of mount you need or want, chances are they have it.

If you're at all like me, you've probably never been completely happy with your mobile mount. But happiness can be found here. A quick look at the chart of available mounts includes a strong gutter clamp model, a trunk lip mount, a trunk gutter mount, and two permanent hole mounts – the standard 3/4 inch hole and an absolutely beautiful 3/8" hole mount that can be installed with standard tools without the need for getting inside the car body. It's called a blind mount and will solve numerous installation problems.

The shining star of the Larsen mounts is innocently called the magnetic mount. So what, you say? You've seen plenty of magnetic mounts, most of them quite useless at speeds above 35 miles per hour since they exhibit a propensity for falling off. This mount is different. It's guaranteed to stay put at up to 100 miles per hour. (Professional race drivers, take note.) The magnet itself will lift 18 pounds, which is more than enough pull to keep it clinging tenaciously to the car. This feat is done by two methods, one using ultra-strong magnets that were recently developed, and the second by the very simple idea of increasing the mount's surface area. It works, and well. With the concern we all have for having our rigs end up in the hands of some rip-offer, the magnetic mount seems the logical choice for ultra-quick removal and hiding.

If the standard line of mounts isn't enough, adapter mounts are available for just about any existing antenna. All you have to do is screw the Larsen on and you're ready to transmit.

The whips themselves are available for any frequency from 27 to 500 MHz. They're made of the highest grade stainless steel and are coated four times to make sure no corrosion gets in the way of signal output. I made the mistake of trying to cut the whip with a pair of heavy pliers, something that can be done with most antennas. No way. The pliers wouldn't even make a dent in the surface. A vise and sharp hacksaw were needed. Following instructions, I cut the whip for 146.52, and was given a 1:1.1 on the swr meter. The 5/8 wave really punches out, even mounted on an angle on the small trunk of my car.

The situation was the same with the base loaded 6 meter whip. Pick your frequency, cut the whip, and see the swr needle move hardly at all. Best of all, my antenna-laden vehicle can be returned to an innocent antenna-free

Tracking the Hamburglar

RIPPED OFF: Icom IC-22 2m transceiver, s/n 1311934. Stolen from vehicle in Regina, Saskatchewan on September 24, 1976. Contact Ed Berryere VE5GE, 1410 East Heights, Saskatoon SASK Canada S7J38S.

TAKEN: Icom 22-S transceiver, s/n 0182. Stolen from my car. Contact Glenn Packard, 28 Bryan Street, Havertown PA 19083.

STOLEN: Icom 230, s/n 240686. Heathkit HA202 40 Watt amplifier – 2 meter, series #03608. Larsen JM 160 magnetic antenna. Taken from my parked car at my house, October 16, 1976. If found contact the Eaton County Sheriff's Department, or Robert Handy, 484-6300, or the Michigan State Police.

RUSTLED: Motorola Metrum II, #C064 with 94, 76, 88, 82, 67, 75, 85, 34, 70, 52, 91, 79. 1B PL. Motorola HT220 H23FFN #TP1174C with separate 12 freq t&r sw, 1BPL, TT on back, "custom WB9BVT" on rear. Robert Scott WB9BVT, 200 W. Chicago Ave., Oak Park IL 60302.

LOOTED: ICOM IC-22A #3405272 with "Kenneth Tendick" on rear, 94, 82, 88, 52, 79, 76, 67, 61. Kenneth Tendick WA9FQT, 1675 Von Braun Trl., Elk Grove Village IL 60172.

LIFTED: ICOM-22A #1827, wired for DV21, Motorola mike. Oscar Klein K9LTC, 18 W. 080 W. 14th St., Villa Park IL 60181.

ROBBED: TR22C #810284, sure mike, BNC ant jack. John Duval K9FIA, 4824 Francisco, Downers Grove IL 60515.

TAKEN: ICOM IC22A #4611. Edward Holz WB9FVG, 7927 S. Komensky, Chicago IL 60652.

KIDNAPPED: FT101B, s/n 316498 stolen in Dallas, Texas on November 25, 1976. Howard Vorpahl, 222 S. Marsalis, Apt. 210, Dallas, Texas, (214) 747-0991.

LIFTED: HR 2B Regency, s/n 49-01623, was stolen on November 26 between 5 & 6:30 pm from my auto parked in my driveway. Also taken was a Heathkit Micoder. My name and call were etched on the side of the inner chassis, and my call was etched near the power plug. A fuse holder had been added to the rear panel (Buss GMW sub-miniature). The light for the dial had been modified so that a short had to be made in the power plug to make it light. Thomas DiMilla Jr. W1VGZ, 8 High St., Saugus MA 01906, phone: 445-0050 8 am to 4 pm; 233-7541 all other times.

LOOTED: IC 22A transceiver, s/n 4611, taken from my Pinto at 4300 W. Roosevelt Road in Chicago on November 23, 1976. Cicero police report number 35310. It has all the standard factory crystals plus 147.45 in/147.75 out repeater set. Also in the set are crystals for MARS. They are 148.01 simplex and 148.01 in/143.99 out. Edward C. Holz WB9FVG, 7927 S. Komensky, Chicago IL 60652.

RUSTLED: 2m-FM transceiver, Regency HR-212 s/n 24-01253 taken from my car on November 23, 1976 in Coral Gables, Florida. Claude G. Edge W4PLZ, 1178 Firthview Drive, Melbourne FL 32935.

HIJACKED: Trio TR 2200 2 meter FM transceiver, s/n 621270, was taken on November 23, 1976 along with my 1976 Chevrolet Corvette. The transceiver was not in its case and had the on/off volume control removed and wired to the console of the car. If anyone finds both the car and radio, keep the radio and give me the car! Richard C. Bean WA1KDL, 103 Forbes Road, Westwood MA 02090.

Social Events

MANSFIELD OH
FEB 6

The Mansfield Ohio Mid Winter Hamfest Auction will be held February 6, 1977 at the Richland County Fairgrounds, Mansfield, Ohio. Prizes, flea market, auction – large heated building. Doors open 8 am. Talk-in 146.34/.94 and .52/.52. Tickets $1.50 in advance, $2.00 at the door. Contact Harry Frierhen K8JPF, 120 Homewood, Mansfield, Ohio 44906 or phone (419) 529-2801 or (419) 524-1441.

TRAVERSE CITY MI
FEB 12

The Cherryland Amateur Radio Club will hold its 4th annual Swap 'n Shop Saturday, February 12, from 9 am to 4 pm at the Northwestern Michigan College in Traverse City. A donation of $1 will include a chance on all prizes. There will be plenty of free display tables for whatever you may wish to bring in electronic equipment and parts. Everyone is welcome and a turnout of over 300 hams and experimenters is expected from all over Michigan. For more information please contact Bill Mader WA8WWM, at (616) 326-6392 or Box 2, Empire AFS, Michigan 49630.

WHEATON IL
FEB 13

The Wheaton Community Radio Amateurs will hold their 15th Annual Midwinter Swap & Shop on Sunday, February 13, 1977, from 8 am to 5 pm, at the DuPage County Fairgrounds on Manchester Road (near County Farm Road) on the west side of Wheaton, Illinois. Some tables will be provided, but bring your own if possible. WCRA invites anyone with an interest in buying or selling new or used electronic equipment to attend this hamfest, which will be inside large, heated buildings at the fairgrounds. Advance tickets (available until February 1) are $1.50, and tickets at the door are $2.00. Write Oran Hiscox WB9JJL, Ticket Chairman, Wheaton Community Radio Amateurs, P.O. Box QSL, Wheaton IL 60187. Commercial exhibitors should write Paul Sexauer W9JTO, at the same address.

GRIFFITH IN
FEB 19

The Lake County Amateur Radio Club's 24th annual banquet is Saturday, February 19 at 6 pm, at the Griffith Knights of Columbus Hall, 1400 South Broad Street, Griffith, Indiana. All the delicious home-cooked food you can eat, wine fountain, entertainment, guest speakers, special awards, door prizes, cash raffles and a dance band after. Tickets are $7.50 each: no door purchase. Write (prior to Feb. 3) to Herbert S. Brier W9AD (W9EGQ), 409 S. 14th Street, Chesterton IN 46304.

VIENNA VA
FEB 20

The Vienna Wireless Society annual Winterfest will be held at the Vienna Community Center. Indoor tables, sales, technical sessions, prizes and food. 8 am to 5 pm. Drawing at 3:30 pm. Admission is $3.00; tables $5.00. Information write Box 418, Vienna VA 22180.

NORWOOD MA
FEB 25

The Norwood Amateur Radio Club will be holding its annual auction on Friday evening at 7:30 pm on February 25, 1977 at the Norwood (Mass.) V.F.W. Post on Dean Street, Norwood. This is just off U.S. Route 1 south.

DAVENPORT IA
FEB 27

The annual Davenport Radio Amateur Club Hamfest will be held Sunday, February 27, 1977 at the Masonic Temple in Davenport, Iowa. Admission is $1.50 advance – $2.00 at the door. Talk-in on 28/88 and 52. Refreshments and tables are available. For info and tickets send SASE to Dick Lane WAØGXC, 116 Park Avenue, So. Eldridge IA 52748.

LIVONIA MI
FEB 27

The Livonia Amateur Radio Club would like to announce that the 7th Annual L.A.R.C. Swap 'n Shop will be held on Sunday, February 27, 1977, from 8 am to 4 pm, at the Stevenson High School in Livonia, Michigan. There will be plenty of tables, door prizes, refreshments, and free parking available. Talk-in on 146.04/.64 and 146.52. For further information, write Neil Coffin WA8GWL, c/o Livonia Amateur Radio Club, PO Box 2111, Livonia MI 48150.

LAPORTE IN
FEB 27

The LaPorte, Indiana ARC will hold its Winter Hamfest on the 27th of February, 1977, beginning at 8 am (Chicago time) at the LaPorte Civic Auditorium. Good food, plenty of free tables, 50 miles east of Chicago. Talk-in on 01-61 and 94, donation $2 at the gate. Information from LPARC, PO Box 30, LaPorte IN 46350.

MARSHALL MI
MAR 5

Michigan Crossroads Amateur and Computer Hobbyists Fleamarket, Junction I-94 & I-69, at the Marshall High School, Junction I-94 & I-69, Saturday, March 5 from 8 am to 4 pm. Forums and YL tours! Sponsors: WB8QQU (MHS "AMPS") and W8DF (SMARS, Inc.). For more information K8UCY – 616-781-3554.

STERLING IL
MAR 6

The Sterling-Rock Falls Amateur Radio Society will hold its hamfest on Sunday, March 6, 1977 at the Sterling High School Field House, Sterling IL. Contact Don Van Sant WA9PBS, 1104 5th Street, Rock Falls IL 61071 for tickets. Advance donations $1.50, door donations $2.00.

PHOENIX AZ
MAR 6

The Winter Hamfest will be held March 6 at South Mountain Park at the south end of Central Avenue, Phoenix. Featuring swap meet, eyeball and pot luck. Sponsored by the Amateur Radio Council of Arizona.

BRIDGMAN MI
MAR 6

Blossomland Amateur Radio Association will hold the 11th Annual Spring Swap-Shop, Sunday, March 6th at Bridgman Middle School gym, Lake St. at Tower, Bridgman, Michigan. Exit 16 on I-94. Expanded facilities, refreshments, prizes, and fun. Talk-in on 22/82 and 94. Table space restricted to radio and electronic items only. Advance ticket donation $1.50. Tables $2 Write: John Sullivan, PO Box 345, St. Joseph MI 49085. Make checks payable to Blossomland A.R.A.

WHITEWATER WI
MAR 20

The Tri County ARC (Whitewater, Wisconsin) Hamfest will be held March 20, 1977 in the Whitewater Armory. Donation: $1.50 in advance, $2 at the door. Reserved tables $2 in advance. Write Doc Walters WB9EMR, 81 N. Main Street, Fort Atkinson WI 53538.

MAUMEE OH
MAR 20

The Toledo Mobile Radio Association, Inc. is sponsoring its 22nd

Looking West

Bill Pasternak WA6ITF
14725 Titus St. #4
Panorama City CA 91402

"I have spent 15 years of my life getting what I consider a good operating repeater working and reliable and I can't stand to listen to it." These were the words of Burt Weiner K6OQK, licensee of the Los Angeles-Mount Wilson WR6ABE repeater (probably the world's busiest and most heavily populated open two meter repeater system), to one of his head control stations, Bob Thornburg WB6JPI. Burt continued, "Unless you want to take over the mess, I will turn it off forever."

The foregoing information was contained in an open letter mailed to almost a thousand users of the WR6ABE repeater explaining the reason that its new operations director, Bob Thornburg, would be removing WR6ABE from the air for a two month "cooling off" period and outlining what operation on the system would encompass when it returned to full time operation on the morning of January 1, 1977. Bob's letter continued to detail the reasons behind his decision. "Over the last several months (years), various techniques have been tried to correct the operating practices of certain individuals. None have been universally successful. At the present time, about 12 people dominate the repeater, almost all from base stations, and all operate without significant regard for other users. Not that their operation is grossly illegal in the FCC sense; they ID and will occasionally even let breaking stations through, but their conduct, language, and subject matter are, in general, deplorable and obnoxious, or at least selfish. The overall complaint could best be described by stating that these individuals use the repeater for their own platform. It is their only outlet for their mental frustrations (which appear to be extensive). They are parasites in that they use the repeater (and some users), rather than utilize the repeater to talk with its users."

From this, you might have a rough indication of the level to which things on ABE had deteriorated. While it's true you cannot be the biggest without expecting to suffer some trouble now and again, ABE was in the past few years getting more than its share. If one was at all observant over this time period, the continuing decay was easy to note. Trying to break, even to contact another station and QSY elsewhere, had become at times an impossible chore. Many of its regular users, a good number who had been a part of its operation from its days as WA6TDD, had gone elsewhere as the problem children began to grab hold of the system. This apathy on the part of a lot of amateurs, their unwillingness to stand and fight along with the licensee, was in my mind one important contributing factor to the overall decay. The unwillingness of the well-mannered operators to take on at least a part of the solution to this growing menace was still another.

By October of this year, typical day-to-day operation of WR6ABE had become a game of which high-powered duplex base station could capture whom, which one could best cover up the incessant and ever-present jamming and, in the end, which station could best monopolize the repeater's air time while saying the least. While technologically the finest open system to be found anywhere, operationally it had reached its lowest ebb.

Why, you may ask, did the licensee do nothing about the situation? You have to know Burt as I do to understand. He is one of those one in a million super nice guys whose path you are fortunate enough to cross during your lifetime. He sincerely cares about the feelings of others and wanted to have his repeater represent his personal attitudes. He wanted it to be an easy-going place where people could chat with one another, get to know one another, make friends, and above all, have fun with amateur radio. For many years, that's the way it was. I remember it being that way when I first moved here almost five years ago. No matter how busy, it was always a place where user respected user, and where pride ran high.

Then along came a new breed of amateur, the kind of amateur who believes a repeater is a gift from on high, put there for him to use as he wishes without any regard for his fellow human beings, be they other users or the system licensee. It takes only a few people such as these to wreak chaos on any repeater and such was the case here. However, Burt felt that the good would triumph in the end and placed his trust in the "good users" to clean up the system. Unfortunately, very few were willing to assume this responsibility. It was easier to just go to another repeater and let the "channel hogs" have their fun.

Without total public backing from the majority of the usership, which was not to be had, Burt apparently reached the conclusion that the best way to solve the problem was to take the system off the air and write off 15 years. That is, unless someone else was willing to try and solve the problem and clean up the mess. WB6JPI agreed to try. How? Bob's letter continues: "My first act is to remove the repeater from the air for 60 days. My analysis of our parasites has indicated that they need and require a host. Removing the repeater from the air will require them to seek another host. They will migrate to other repeaters and with luck they will like it there and stay there. (Editor's note: Virtually every other area repeater has a much higher degree of regulation and discipline and, in my opinion, a takeover of another system in a like manner to the ABE takeover is not likely. Not to say that it might not be attempted, but rather the likelihood of success is small.)

"The repeater will be forced to behave. A tight group of control operators will be trained and ordained. This group will have the power to enforce (by various means, including shutting off the repeater) certain rules on the operation and behavior that will be used on the repeater. Subject matter will be censored, as well as language and operating procedures. Freedom of speech and 'right to use' will have no precedence. The decision of the control operators is absolute and without appeal. If you don't like it, use some other repeater. This excruciating, difficult, arbitrary, and strict control will last for as long as it takes. It is hoped that out of the war will emerge a group of users with an attitude and behavioral pattern that will set a new standard for ABE. Those who are attracted to a tightly controlled repeater will survive and continue demanding from new users a high level of performance. Therefore, it is hoped that the tight control, censorship, and other direct user controls will only be necessary for a few months. It will be self-perpetuating. In a few years, the cycle may have to be repeated. It may not always work.

"Again, ABE is trying something new — user attitude adjustment. To my knowledge, it's never been done. We have a good 'handle' on jammers and jammer-related problems and I feel that Paul W6AOP and his team can thwart the threat of unidentified illegal and destructive use of the repeater. Tight control will be established to ensure that the 'legal' users will behave. If it doesn't work to my satisfaction, then indeed ABE will go dark."

User reaction on ABE as well as other repeaters was interesting to note. It ranged from, "This is a public utility and you have no right to do this" (editor's note — while this kind of statement might seem as absurd to you as it does to me, nevertheless it was indeed heard time and again as a reason why the owner was obligated to keep the repeater in operation), to "Maybe I'll sue; after all, I had to buy a special set of crystals to operate this repeater and now they're no good." It included, "We'll put up a repeater of our own on this channel pair," and, of course, "You can't tell me how to operate my station or what I can say on this or any other repeater; I'll say anything I like . . . it's my right." There were more; these are just a few of the ones that still stand out in my mind. It was quite obvious that those making these statements had never taken the time to read the rules and regulations; they failed to realize that this and/or any other repeater they would chance to operate was there through the benevolence of another amateur who, through the goodness of his heart and technological skill, had in effect invited other amateurs to share the use of his station. For indeed, what is a repeater other than another amateur's station there for you and me to use?

While many users did voice support for Bob's decision both on and off the air, a lot of times the tone of voice made you wonder if the gesture was half-hearted. When I would hear such statements, I would wonder why people had waited till now to make them. Why had they not taken affirmative action themselves long ago to remedy the situation before it had gotten this bad? Could it be that deep down inside they were mad about losing use of the system regardless of how bad operating procedure had gotten? I still wonder. Oh, there were some sincere "well-wishers," but they were far from the majority.

Reaction elsewhere on other systems was quite interesting. For a long time, other systems had considered ABE as the "jail" that housed the outcasts from two meter FM society. As long as ABE was there, everyone was safe. Now the "jail" no longer existed and a number of systems took interesting action. A few announced that they would be going either part-time or full-time tone access while others went to revised operating schedules. A number of previously 24 hour systems now shut down at midnight or thereabouts, when no control operator is present, while others have announced that control stations are continually on duty. While no one will admit that ABE's going away is the reason, it seems very coincidental. Anyhow, the amount of malicious jamming being suffered by various systems seems to have increased since ABE went dark. The jammers are not to be confused with amateurs who abuse the privilege of operating a repeater; they are two entirely separate entities, two entirely separate problems. These problem causers seem desperate to find new homes and new audiences, and to thwart this, a good number of systems have *"ordered"* their users to pay no attention whatever to this problem, thereby taking away the audience factor. In reality, this is the best and many times the only weapon to use against illegal malicious interference.

The big questions seem to be: Can the directorate of WR6ABE succeed in changing the operating habits of a large number of amateurs and instill in that group a sense of total pride and respect for their fellow amateurs? Also, do they have any right even attempting this? To answer the latter first, indeed they do. Their obligation is clear and that obligation is not only to amateur radio but to society in general. With the advent of the $9.95 public service monitor portable radio, there is no telling who your audience might be. We must always assume that someone without the understanding of amateur radio is listening and be aware that saying the wrong thing might offend and alienate that kind of person. We need friends, not enemies, and if this means that we must clean house once in a while, then it best be done.

Then, too, is the fact mentioned earlier that a repeater is not a God-given gift, but rather like one amateur inviting you into his shack to use his station. If you used his station in a manner he deemed improper, he

would ask you to stop. If you refused, he would probably pull the plug out of the radio rather than permit this transgression to continue. By the same token, there is no obligation on the part of any repeater to adhere to the will and directive of its usership unless it happens that the sponsor of the system is a club corporation and the membership comprises the shareholders. Then and only then do users have the right to voice any opinion in the operational parameters and guidelines of the system. In the case of the individual owner-licensee, there is no obligation to provide any form of service to anyone at any time. It's up to him to decide when it will be on the air and how it will be operated. It's what one might term a benevolent dictatorship. A repeater owner has zero obligation to users; however, users have specific obligations to adhere to the wishes of the licensee. After all, in effect you are in his home; you are using his station.

Now I can hear a lot of teeth grinding and see a lot of fists clenched by people who are saying to themselves, "How can he say that? He's selling users down the tubes; why, it's we users who are the most important aspect of any repeater; we support the repeaters; we are the people that by virtue of our use of a repeater give it a reason to exist." However, after this anger wears off, I ask you to sit and think as I did and ponder the following: Your license gives you the authority to operate an amateur station, your amateur station, on a certain portion of the electromagnetic spectrum. The portion of the spectrum you are permitted to operate is governed by the class of license you hold. No where in the rules and regulations that govern your license does it say that your license or mine gives us the right to walk into the home of another amateur, without his permission, sit down in front of his amateur station, and make use of his equipment against his will. If he does not want you in his home, he has a perfect right to tell you or me to get lost. Our licenses give us the right to respectfully share the allotted spectrum with others on a non-interfering hasis. Our licenses do not give us the right to operate a repeater just because it is there; we have the right only to use our radio to transmit on a given frequency, be it a channel set aside by local agreement as the input of a repeater or not, and there is nothing in the rules that states we must be repeated or relayed via a repeater. That is left to the sole discretion of an individual who happens to hold license on a repeater. As users, we have the right to own and use radios; being repeated is a privilege, unless you either own the hardware or part thereof or hold the license. You and I constitute a subculture known as the "repeater user," and our only "right" is the right to say thanks now and then to those providing repeaters as a service to us. It's a hard, cold fact of life, and one that you do not consider until the day that your favorite repeater goes away.

The next question: Can the concept of user attitude adjustment as outlined in Bob's letter succeed? Can the attitude of "me first" and "I have more right to be here than you" be replaced by a willingness to work together for a common good? Can the human nature of a few be changed to benefit many? When ABE comes back on the air, will it be greeted by a group of enthusiastic people, eager to build a new world with a goal of a new standard of excellence in repeater operation and thereby setting a new standard for a nation to emulate? Or will the promised vendetta of a few selfish people force the final decision to be made, the decision that would spell an end to more than 15 years of WR6ABE and possibly signal an end to open format relay communication elsewhere? Many repeater people, both owners and users, will be watching this experiment, and once more it looks as if Southern California is about to set another trend. Will it work? Only the future will tell.

Last month we introduced WR6AKG and Keith Glispie WA6TFD to you. Keith is the young amateur who saw a need to provide children of school age who happen to hold amateur licenses a place of their own to communicate. Out of this need WR6AKG has been born. As of this moment, November 20th, Keith is busy at work readying his PYE Communications Model FM-50 repeater for service. While the SCRA has yet to confirm a final channel pair for this endeavor, the inverted split-split channel pair of 146.925 in, .325 out looks like it will be AKG's home. This channel pair is currently occupied by a private system in Palos Verdes, the owner of which, I have been informed, has agreed to co-channel with the AKG project. The only thing holding up final test sanction is that the output of a privately owned remote-base also utilizes .325 as a two meter downlink, and unlike repeaters, remotes are not SCRA coordinated. An organization known as the Southern California Repeater and Remote Base Association handles coordination of anything on 60 meters and 450 on up. Therefore, it is necessary for SCRA to contact SCRRBA and in turn have SCRRBA contact the remote owner in question and request that he either also agree to co-channel with AKG or that he agree to re-coordination to another two meter channel. It is this final step that Keith now awaits. Will the remote agree to co-channel with what might become one of the area's busiest open repeaters from sunrise, well . . . to sunrise, I guess? We should know soon.

However, with things starting to look quite positive after almost two years of work, the following letter went forth to all school radio clubs within the Los Angeles Unified School District from DHART, AKG's sponsoring organization.

ATTENTION ALL AMATEUR RADIO CLUB MEMBERS, WHETHER LICENSED OR NOT!

The Dorsey High Amateur Radio Team (DHART) is proud to announce a new idea in amateur radio. The idea is to invite all members of Junior High, Senior High, and even Collegiate and Vocational Schools to join us on two meter FM. If you are saying to yourself the idea is not new, listen further.

A new repeater system, licensed to the Los Angeles Unified School District, through WA6TFD, will be in service within 2 months. Ah, but this is only part of it. About 2 years ago, DHART found that there was a valuable need to keep in touch with other radio clubs at other schools to keep up with the new ideas, projects, etc., that another club may have. So we talked to several other schools, who also agreed that there should be something done. Some schools had tried to give their young hams a chance to get into 2 meters and the idea of "repeaters." Amateurs already established on repeaters didn't exactly see eye to eye, so the newcomers felt rejected and lost interest in repeaters.

With all comments and ideas in hand, and with help from outside organizations such as PARC, members of DHART set out to find the solution, and that was to have a school "interlink" repeater system instead of just one channel talking directly to one school at a time. Since some schools are situated in remote portions of the county, simplex operation at times would be very difficult. With this in mind, we set out to build WR6AKG, a repeater which was built from bits and pieces from everywhere. It was finally completed after long hours of hard work.

We found that it would almost be impossible to find a repeater channel, but we went ahead and tried anyhow. We wrote the SCRA and told them that we wanted to put a repeater up on two meters and that it would be used as a school interlink system. They sent us a letter back saying that the band is quite full and that they would try to find something. About two days later, we received a call from the SCRA saying that they were trying very hard to find an open channel on which to put our machine.

They were pleased to finally see a repeater go up in this crowded system that finally had a purpose, and that purpose is to stimulate amateur radio interest and promote student communication between themselves and between schools.

This, in other words, is a pilot project which has never been tried before and will be the first of its kind anywhere. Fellow hams, this is *your* machine. It is provided for *you* to stimulate *your* interest in amateur radio. If you want to, set aside time for code practice, operating procedures, radio club rag chew, IC logic lingo, etc. The list goes on and on. Remote control operations, crossbanding, low band operations, field days, etc. Invite your friends who are not hams or even CBers to join you and find out what amateur radio is all about. Handled just the right way, your school can have more hams than you can deal with! You never know what can come about!

DHART hopefully will have WR6AKG in operation before December. The test location shall be in the Baldwin Hills area, with 50 Watts transmit power and .2 microvolt receiver sensitivity. We are trying to get the site atop Mt. Wilson at channel 58 for all-around coverage. The repeater frequencies at this time are unknown, but you shall be notified as soon as we are. If you would like to find out more about this program, give suggestive comments, or find a 2 meter FM radio for your school, contact the control operator of WR6AKG, Bryan Glispie WA6TFD, 3861 2nd Ave., Los Angeles CA 90008, (213) 295-0721 or DHART, 3537 Farmdale Ave., Los Angeles CA 90016, (213) 296-7120 Ext. 1.

If you have 2 meter equipment that may be used by other schools, please call DHART and we can list your school as a source for a radio.

If you have any suggestions or donations please contact us.

Yours truly,
Club Advisors
J.A. Martin
Traci Campbell

While amateur radio and amateur radio clubs have been around both public and private schools probably since the inception of amateur radio itself, this is the first time (to my knowledge) that it may play as important a part in children's education as now seems possible. The potential for the concept that the Dorsey High Amateur Radio Team is pioneering might just go down in amateur radio history as one of its finest hours. I personally suspect that it will be one quickly emulated elsewhere. My hat is off to Keith Glispie and DHART for finally giving a real purpose to amateur relay communication and thereby bringing amateur radio a bit closer to the non-amateur world. From this only both can profit.

Calling all boats, calling all boats! Planning to sail or power your way into Los Angeles Harbour or Marina Del Rey? If so, it might pay to put 146.805 – 146.205 in your two meter radio. This inverted split-split channel pair is the home of WR6ACK, a newly redesigned repeater system whose purpose will be providing inter-boat and boat to land communication for aquatic oriented amateurs.

If you have been following Looking West for any length of time, you might remember a few years back when ACK was Los Angeles' first open autopatch and also the first open

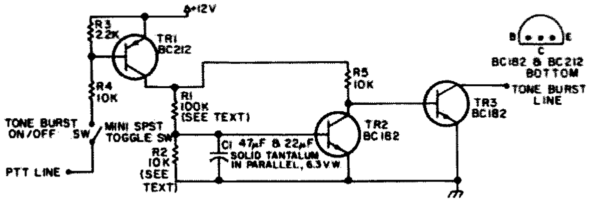
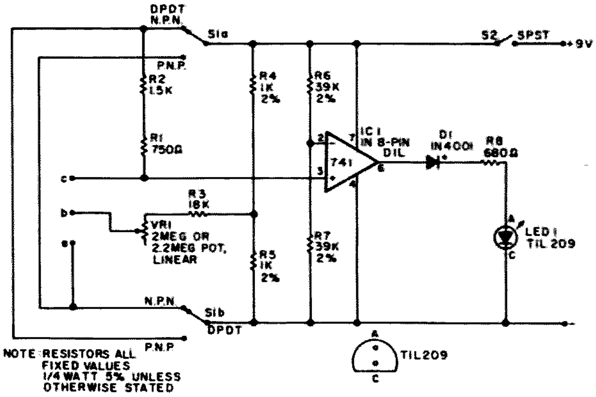
Circuits²

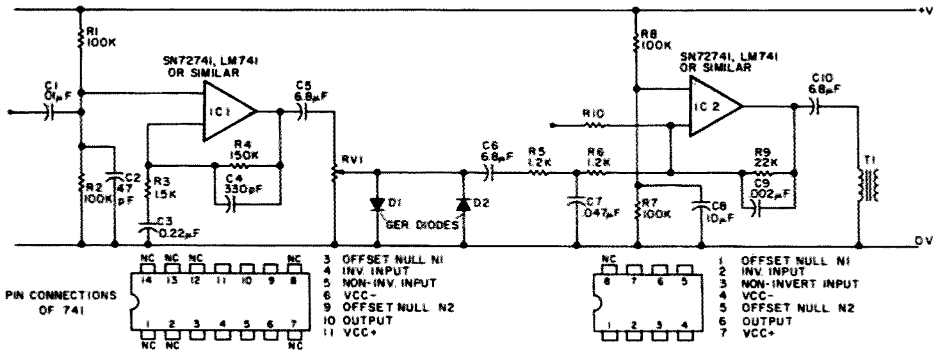
Want a free copy of any 73 publication? Sure you do. Just send in your favorite circuit, or even one that you don't especially like. If we print it, you take home the book of your choice.



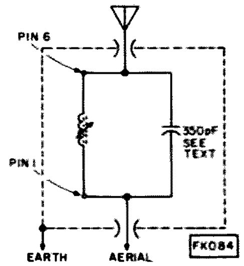
A tone burst timer for the Kenwood TR-2200A, with the length of the burst determined by the values of R1 and R2 so long as their ratio remains 10:1 (i.e., 100k:10k, 150k:15k, etc.). The burst length (with illustrated components) is about 400 milliseconds using a 12 volt supply. Reprinted from International Mobile News.



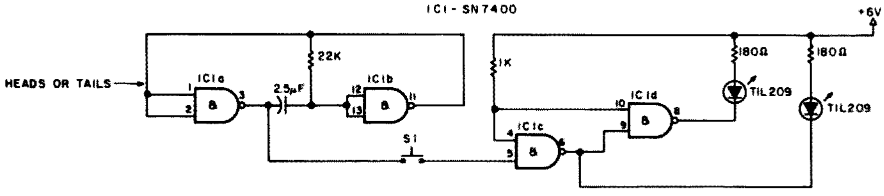
Simple transistor tester. Indicator lamp LED 1 is fed from the output of the op amp via D1 and current limiting resistor R8. D1 is included because the output of the op amp, when it is fully negative, is about 2 volts positive. Without D1 that would be just enough to produce a visible glow in LED 1, but with the voltage delay D1 produces, the LED is fully doused when the op amp output is negative. Reprinted from Practical Wireless, *England.*



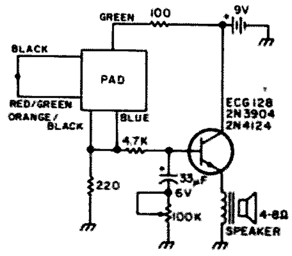
Speech-amplifier clipper using the 741 op amp. As shown, the unit will deliver about 30 V peak to peak output, but can be easily modified for less output by decreasing R9 and increasing C9. What's more, T1 can be eliminated to cut output to 15 V peak to peak. Reprinted from The Short Wave Magazine, *England.*



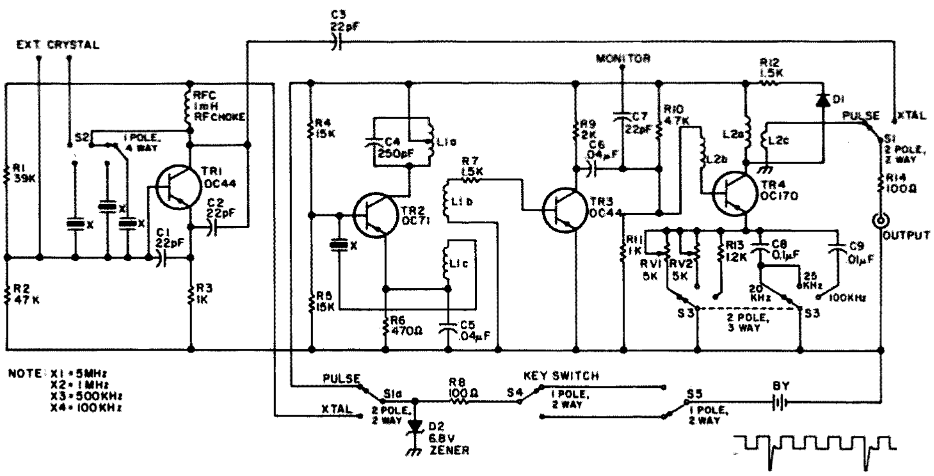
Tone cut control, for reducing the level of heterodynes. Also useful in compensating for deficiencies in small speaker systems. For best rejection of an unwanted signal, aim for minimum capacity and maximum inductance. Connect the trap as close as possible to the receiver antenna terminals for highest efficiency. Reprinted from Practical Wireless, *England.*



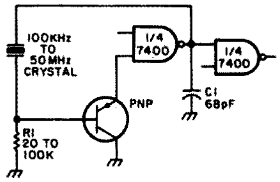
Low cost "heads or tails" game. S1 must be a push to make, release to break, switch. Thanks to D. Manoharan, Kuala Lumpur, Malaysia.



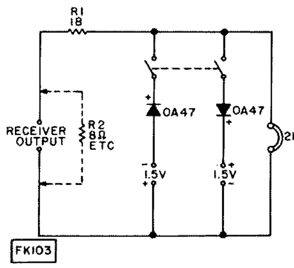
Hookup for an acoustical pad. Put the mike to the speaker and press the button. Not recommended for mobile use, as three hands are required. Reprinted from SCRAMSGRAM.



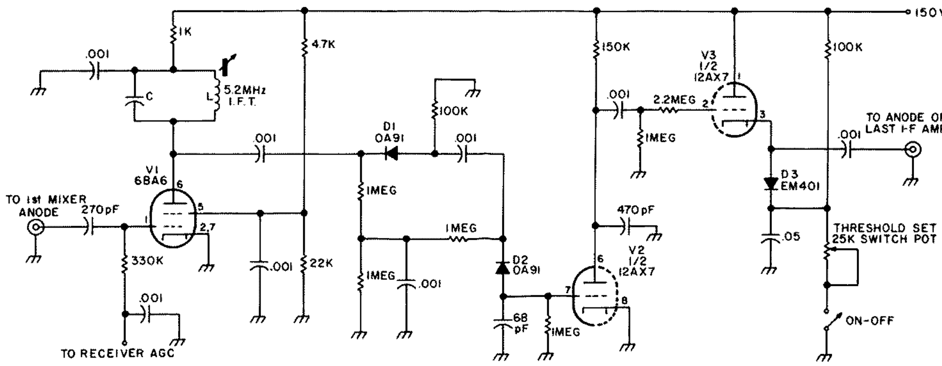
Crystal-controlled calibrator which generates pulse type signals at 20, 25, or 100 kHz. The unit covers the whole spectrum into the VHF region. Reprinted from The Short Wave Magazine, *England.*



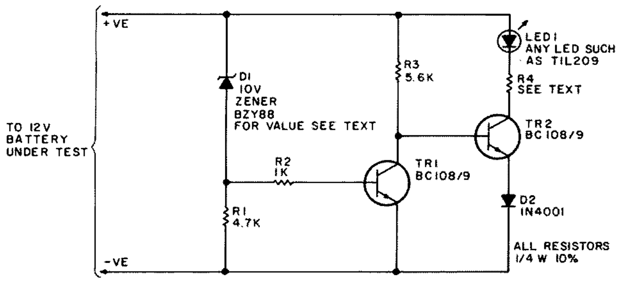
A TTL-compatible crystal oscillator. Adjust R1 for about 2 volts at the output of the first gate. Adjust C1 for best output. Thanks to Arvid Evans K7HKL.



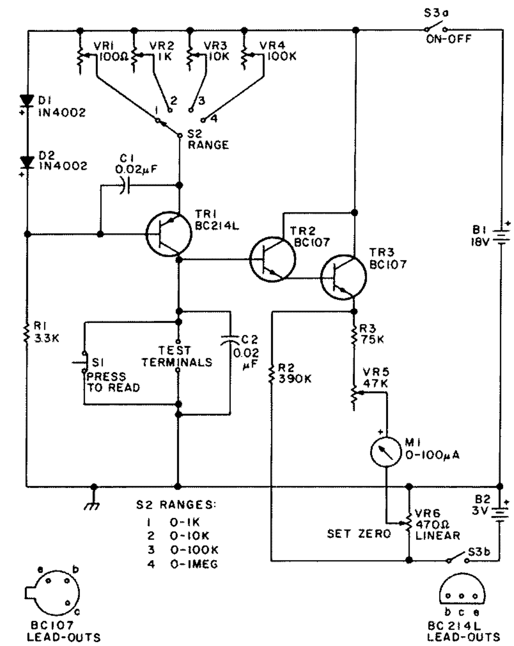
The basic noise limiter, for use with high impedance headphones. Very effective when your receiver is operating at maximum gain on a weak signal. Diodes must be germanium type. For receiver outputs of more than 15 to 80 Ohms, increase R1. If you're looking for a lower impedance load, use a 3 to 8 Ohm resistor across the input, as shown by the dotted lines. Reprinted from Practical Wireless, *England.*



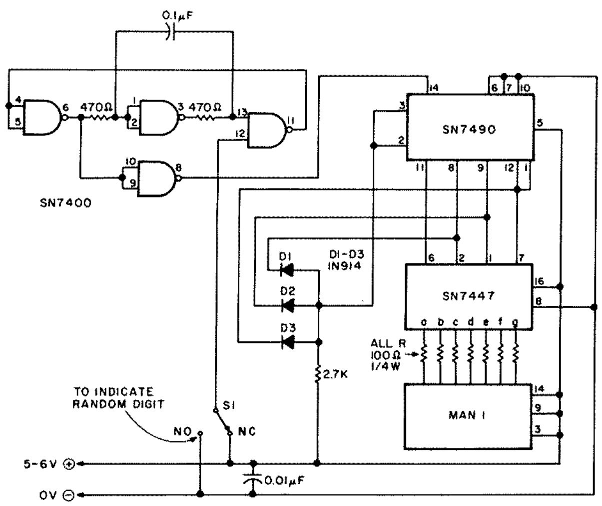
A cheap and dirty noise blanker, using tubes. FET conversion would be easy, as the circuit illustrates. Receiver oscillator line supplies 150 V, with AGC applied at V1. Circuit is especially good with FT-101 series. Reprinted from Amateur Radio, *Australia.*



Early warning circuit for battery discharge. Circuit shown is for 12 V operation, with zener D1 controlling low voltage cutoff. R4 = (voltage of zener diode)²/LED current. Reprinted from Practical Wireless, *England.*



Linear scale ohmmeter, designed to provide accurate measurement and a linear resistance scale at the high end. The circuit has four ranges, and another meter with a current range of 10 uA to 10 mA and sensitivity of 10,000 Ohms per volt is needed for setting up. Reprinted from Radio & Electronics Constructor, *England.*



Electronic digital dice game. Thanks to D. Manoharan, Kuala Lumpur, Malaysia.

NEVER SAY DIE

EDITORIAL BY WAYNE GREEN

from page 2

we are incredibly strong when we are able to come out ahead over a combo like that.

Some readers get bent out of shape when I enthuse over things which I find fun. I've always tried to share my enthusiasms with everyone I could, whether it be for a Porsche, FM and repeaters, RTTY (you probably won't believe how many years we had to fight the ARRL to try and get RTTY on the ham bands!), SSB, SSTV, travel, OSCAR operating, etc. I get much more enjoyment out of anything if I can share it and interest others in joining the fun. When I hear music I really like, I want to play it for everyone (it's a good thing it is illegal to play music over the ham bands!).

The Porsches are long gone, as are my plane, yacht, and Arabian horse. These days I'm lucky if I don't have to turn back a couple of items at the A&P at the checkout counter . . . one of the penalties of opting to "own" my own business instead of comfortably working for someone else. Now my employees own the planes, horses, and Porsches. That's the American way . . . right?

BUT DOES HE KNOW THE CODE?

From a clipping out of the *San Jose Tico Times* in Costa Rica (the sun never sets on the *73 Magazine* newspaper clipping input . . . with 100,000 readers watching papers all over the world for interesting items on hamming, CB, flying saucers, and who know what else?) . . . oh, yes . . . the clipping . . . it seems that Donald Nixon (nephew of guess who) got a ham ticket with the call TI2TT. He lives in Moravia.

I've gotten some interesting poop sheets (postmarked Hartford?) about retiring to Costa Rica and have been thinking of getting down there to see what is involved as a matter of interest to readers. I wouldn't be interested for myself until they improve the skiing facilities a whole lot.

Give That Professional Look to Your Home Brew Equipment

- - win prizes

Have you ever built a project and then felt disappointed with its appearance after it was done? Do you admire the beautiful projects that grace the pages of most electronics magazines? Would you be interested enough to spend a little time learning how to make your projects look better, be easier to build and service, and perhaps work better? If you answer a resounding "yes" to these questions, this article is for you! One of the problems facing electronics people who like to build their own gear is that there is more emphasis on *circuitry* than on nuts-and-bolts construction. You see this whenever you pick up a magazine and read a construction article. All too often you get a lot of "how it works" theory, a few paragraphs of "connect the green wire to point C" construction, a "how to use it" section and a schematic. That leaves a lot of open avenues for construction – great for experienced constructors, but a stumbling block for less knowledgeable people. We are going to get you started with the basics in electronic construction, and well down the road to successful project building.

The photo is a shot of the author's test bench and shows some homemade equipment. Everything you see here was built over the past two years using ordinary tools and techniques about to be discussed. Granted, large and costly projects such as an oscilloscope and frequency synthesizer are beyond the abilities of most people, but this is just to show you what can be done at home! Why not build your next project like a pro using our methods?

Good tools are the most important part of electronic project building. They save you time (your time is valuable!) and temper by making the work easier. Here is a *minimum* list of tools you should have:

Needlenose pliers
½" blade diagonal cutters
Adjustable wire strippers
25 Watt soldering iron for ICs
100 Watt soldering gun or iron for wires
1 lb 60/40 rosin core solder
Screwdriver set
Nutdriver set (especially ¼" unit)
Heavy duty jackknife (for deburring holes)
¼" hand drill or drill press
Set of drill bits
12" square/ruler

Check over your tools and be sure that all cutting edges are sharp. If you have to add tools, get good quality ones. The extra cost of good tools pays off in the long run. They stay sharper and don't break as easily. You will probably have to add tools to your present ones to handle the demands of different projects (e.g., chassis punches, etc.), but this list represents the bare minimum.

Okay, we're ready to start. We'll take each stage of the construction process step by step. To highlight the process, we are going to assemble a 5 volt, 1 Amp power supply along the way. You are welcome to build one along with us if you want. A 5 volt power supply is a great addition to any lab that works with digital ICs!

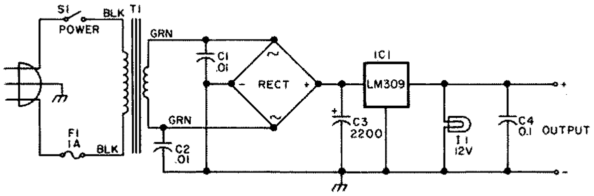

Fig. 1. A simple 5 volt, 1 Amp power supply. C1, C2 – 0.01 uF disc capacitor; C3 – 2200 uF 25 volt electrolytic capacitor; C4 – 0.1 uF capacitor; F1 – 1 Amp 3AG fuse and holder; I1 – 12 volt, 50 mA lamp and holder (Radio Shack 272-322 OK); IC1 – LM309K voltage regulator; RECT – 6 Amp, 50 piv bridge rectifier; S1 – SPST toggle switch; T1 – 12.6 volt, 1 Amp filament transformer; Misc – cabinet (LMB442 used in example), 3 wire cord and plug, binding posts, wire, etc.

Appraise the Project

The most logical way to start an electronic project is to appraise it for the best way to build it. When you find something you would like to build, you should start by looking over the circuitry and any method of construction that may be shown. If you are a newcomer to electronics, you may want to build a kit the first time out and then start building projects out of magazines and from schematics. This makes electronics a lot easier if you

start with a "paint by numbers" kit and gradually work up to more challenging projects.

Start by reading over the project (if it's out of a magazine) or by checking out the schematic. When you are reasonably familiar with it, ask yourself the following questions:

1. How am I going to assemble the electronics?
2. Am I going to build the completed project in a cabinet?
3. Are there any critical areas in the electronics that require special care, e.g., high gain amps?
4. Are there any special requirements in the mechanical construction, e.g., shielding?
5. Can I get all of the parts?

If you are building the project from a magazine article, you can answer the first four questions simply by copying the author's finished unit. The fifth question must be answered by you. If you can't get all the parts, or if they cost more than you can afford, don't build it. Instead, set the project aside, and tackle it in the future if you really have your heart set on building the item. If you are building your project from a schematic or custom building a magazine project, you'll have to answer these questions yourself and provide the solutions. Experience is the best teacher here. The schematic should give you some clues. Table 1 lists some pitfalls to watch out for.

Needless to say, the list could go on, but Table 1 is a sample. Make allowances for these things. Leave room for metal shielding, bypass capacitors, and heat sinks. Lay out parts carefully to keep input and output separate on high gain amplifiers (that includes i-f amplifiers) and leave space for heat sinks if necessary. Watch lead dress in logic circuits and VHF-UHF circuits, too. Good grounds are also very important. Keep these things in mind, along with anything else you can dig up on the project. All of the items mentioned here should influence how you build your project.

How would you like to sit down to a bench like this? This is part of the author's setup and all equipment is homemade. Shown from left to right are two stacked power supplies, a 0 to 60 MHz frequency synthesizer (signal generator), a frequency standard and digital multimeter on top, followed by a stacked function generator and counter. A triggered sweep oscilloscope is on the far right, and is topped by a digital alarm clock.

Collect the Parts

Now that you are reasonably familiar with what you are going to build, you can get the parts. There are many sources of electronic parts, of course, but you should start with your junk box. Don't have one? Start collecting old radios, TVs and other cast-off electronic devices and strip them for parts. You'll need hardware such as nuts and bolts (bought a box of screws lately?), so save all that you can get. Junk boxes are good for the basic stuff you need for a project. If yours is well equipped, you might be able to build an entire project, such as our power supply, but this is rare. For any ICs or other semiconductors and parts, you may have to turn to your local dealer, so get to know him well, if you don't already. Another parts route open to you is the surplus mail order dealer listed in the back pages of most electronics publications. If you haven't tried these dealers, you are missing out on some great bargains. But beware of reject or retested components. They can cause more problems than you would believe! Pros use quality, name brand parts – this one move often saves hours of troubleshooting later! All you have to do at this time is collect the electronic components. Leave the cabinet selection until later if you are "rolling your own" project, or buy the one called out if you are duplicating someone else's device.

Once you have all the parts, you can test them if you desire. Test any used parts that show signs of being hot; otherwise, this step is optional. Many people check all their components to save troubleshooting later, and that pays off with parts of poor quality, but this shouldn't be necessary if you use good quality parts as we recommend.

Select the Cabinet

Now that you have all the electronic components together, the time has come to select a cabinet to house your project, and perhaps a chassis as well. The secret of success in selecting the right housing for your equipment is *advance planning.* The idea is to get a cabinet that is large enough to house all of the parts of your project, plus allow room for easy servicing and future modification. You do not want the cabinet to be too large; this is an unnecessary expense, and oversize cabinets mean excessive bulk. Here's how to select the box or chassis that is right for you with a minimum of fuss.

The first step is to visit your dealer and find out what cabinets and chassis are available to you. You might also want to write the manufacturers listed at the end of this article for catalogs – this will help in your selection. Next, lay out the parts that normally mount inside the cabinet on a table. This normally includes circuit boards, large caps and transformers. Lay out the parts like you were assembling the unit into a cabinet. Allow at least 1" clearance around the circuit board (if used) and any adjacent parts. Separate heat producing parts such as transformers, power resistors, and power transistors at least 2" from any other parts. The back cover is a good place for resistors and transistors, while the transformer may be mounted toward the rear. This is just a "first fitting," so you don't have to place the

Pitfall	Solution
High gain amplifier or tuned amplifiers	Extra shielding may be required.
High gain amplifier or tuned amplifiers	Inputs and outputs well separated.
High gain amplifier or tuned amplifiers	Power supplies remoted or shielded.
AF or RF oscillators	Good shielding and bypassing of power leads.
AF or RF oscillators	Sturdy mounting of coils and capacitors.
Digital logic ICs	All power supply leads must be kept short and well bypassed with capacitors.
VHF-UHF circuits	All leads must be kept short.
Power supplies or power handling circuits	Good heat sinks for all power devices.
Power supplies or power handling circuits	Heavy wire where necessary to minimize losses in power.

parts exactly. Measure the height, width, and depth of the layout and you have the *minimum* case dimensions. Consider what components you have to add to the front and rear panels. If they would interfere with the parts layout you made, add more space to the *minimum* dimensions. Meters and speakers are great space hogs in this respect! Continue to add parts to the front and rear panels, making corrections to your minimum dimensions as necessary. Be conservative in your estimates. A little extra room in the layout makes construction and servicing much easier. Also, you may suddenly discover the space for shielding, as in the case of a radio receiver project. Consider using chassis in your more complex projects. You can mount your PC boards on top, over a suitable sized cutout, and this will make construction and servicing a snap. Chassis are also used as shielding boxes – this may be necessary in a project where many sensitive circuits must be placed in the same case. Our frequency synthesizer is a project in point: It uses 6 fully enclosed chassis boxes to isolate the many VHF frequencies the circuits generate from each other.

Finish up your case or chassis selection by taking your dimensions and selecting a box to fit. Since you will probably have some oddball dimensions, you may have to look for a larger box or an odd sized one. With practice, selecting a case can be done quickly, with just a few measurements and the catalogs.

Build the Electronics

This is the largest step you'll probably have to make, but we are going to simplify things a bit. Because of space limitations, we can't fully discuss the wiring phase of a project. Instead, let's look at the highlights of electronic construction.

To start with, there are three basic ways to assemble an electronic circuit. You can use a PC board, a perfboard, or mount all the components on the project's cabinet. Often two of these techniques are combined, as it is common to mount small components such as caps, resistors, or transistors on a PC/perfboard and then mount large components such as transformers and speakers on the cabinet. So which construction method is best for you? The choice is fairly easy – if a PC board is available, or if you feel you can make one, use it. PC boards are also recommended for complex digital circuits (about 10 chips or more) and critical circuitry such as high gain amplifiers. Perfboard construction is a handy method of construction for simpler, less critical circuits. Construction may be a little harder than a PC board because you have to figure out the placement of each part as you wire it up. On a PC board, the designer has determined layout for you and assembling a PC board (nicknamed "stuffing") is often like building a kit – easy! Another method of construction is assembling all the parts on the project's cabinet and wiring them up. This method works fine when there are few parts and most of them are made for chassis mounting. Small parts are often mounted on terminal strips to keep them from touching the chassis. You will often see this method used in power supplies (such as ours) and other simple projects.

Laying out your circuitry isn't necessarily difficult if you don't try to rush construction. Just take your time and use some intelligent planning and the results should be good. If you are using a commercial PC board, you can skip this part; just stick the parts in as per the pictorials and solder them! But if you are working with perfboard, or *laying out a PC board,* follow our hints to ease your job.

The schematic, and any other circuit information available, has the most powerful influence on how a circuit should be built. For example, if pictures or drawings are available, you might get by building your circuit from these. Or, at the very least, these illustrations can give you ideas on how to lay out the circuit to suit your own needs. So it goes without saying that you should read over any texts and illustrations available on your project before starting! There just might be enough information available to skip this section! Also you want to look for "problem areas," parts of a circuit that are sensitive to component layout. Examples of this area: grounds in HF to VHF circuitry, power supply bypassing around digital or linear ICs, component lead lengths, and so on. A good author will point these things out and probably more, so when a suggestion is made to handle these problems, take heed! *Caution:* If you see many problem areas in a project and you aren't sure you can handle them all, get a PC board if available, or drop the project. This can save you grief!

But suppose you are building a project from just a schematic. Now you have a challenge! But here's the basic way to go about building the circuitry: First, select a board large enough to hold all of the parts, then refer to the schematic. You can often lay out the parts on the board just like the schematic – you might consider this. This makes complicated circuits easier to trace, but a well-drawn schematic is required. Otherwise, try this: Stick the major parts (e.g., transistors, ICs, etc.) on the board. Then stick in the smaller components around the pins of the IC or transistors they would connect to. Try to position the parts for shortest lead length. And remember how you appraised the circuit to begin with? Try to account for any pitfalls you found at that time. You may do this technique for just one stage at a time, as in complicated circuits, or do an entire circuit at once! Some tips to use in your layout and construction: Leave plenty of room for all parts, avoid "layered" construction, or the placement of, say, resistors on top of capacitors, and always use sockets on ICs. When you have a layout that satisfies you, wire up the parts. Use #18 to #24 bare tinned copper wire for all grounds and power supply leads if possible. When you are done, check your work and plug in any ICs. You might be able to check out the board to see if it works, too.

Tackling the Cabinet

Now you get to lay out, machine, and label the cabi-

net. And in the bargain you'll get some exercise! Start by laying out the cabinet. You should have a general idea of what goes where in the cabinet from the section on its selection. Now improve on that by collecting the parts that would mount on the front panel. Oh yes, don't forget the box you selected! Play "chess" with the parts by placing them on the outside of the box and moving them around until you get an arrangement that looks aesthetically pleasing. Some tips to aid you: Lay out controls in a symmetrical manner – that means in a straight line (if you have many controls, stagger them). Balance them so they are neatly centered between the ends of the box. If possible, group the controls by function. Mark all hole locations. Masking tape works well here. Then follow the same procedure for the bottom and back of the box. Be sure that there is still room for all of the parts. If you need ideas for your cabinet layout, why not check out some commercial gear? This can be very helpful if you are stuck.

Once you have the locations marked, you can start drilling them. A center punch is recommended to punch all hole locations for greater accuracy, but this is an option. When you have all cabinet holes drilled, use the knife to deburr them. Then tackle special holes, such as square ones for displays or round ones for meters. You can cut these either by drilling holes around the inside edge of the cutout, punching out the slug and filing to size, or by using a chassis punch. A sabre saw could also be used, but it would mark up a painted panel. The choice is up to you! After you are done, deburr any leftover holes and wash the box. Use detergent and water if the box is painted, or a scouring pad and detergent if it is bare aluminum. Finish up by drying the box thoroughly.

You might want to paint the box. For best results, warm up the box to about 30 to 40° C. Then use your favorite color of aerosol spray to do the job. Follow the instructions on the can and you should get good results. (Incidentally, it is often cheaper for you to buy an unpainted box and paint it yourself!) Let the box dry in a warm dust-free place overnight. Then, take it and apply a light coat of clear acrylic spray; this will make application of the labels easier. Let it dry several hours.

Now you can apply decal labels to the cabinet. If you don't have any, you should be able to get them from the larger electronics distributors or perhaps by mail order. You can also get alphabet sets from most drafting suppliers for low cost. Typical names for decals are Letraset® or Technilabels®, and they come in sets for experimenter, ham, etc. Common words are already spelled out for you and they are very easy to use. The drafting alphabet sets have names such as Paratipe® and Zapatone® and have only letters – you must make up the words yourself. Applying these labels to the cabinet is easy – they just rub on with a blunt pencil. If you get a word or letter in the wrong place, it easily comes off by placing a piece of cello tape over it, rubbing it, and pulling it off. Be sure that you allow plenty of clearance for the knobs when you apply the labels. After you label the front you may wish to label the rear, too. This will complete the professional appearance of your equipment! Spray the outside of the cabinet with clear acrylic spray when it is labeled to your satisfaction and let the box dry.

Final Assembly

I can imagine that you are getting pretty excited by now, because you are in the homestretch! Now you get to connect up a lot of loose parts and see if the project really works.

Complete the final assembly by mounting all the parts on the front panel. Install the knobs (did you get good-looking ones?) when you finish. If you did everything well so far, the project should go together like a kit – fast and easy! This is something to shoot for. Continue with the rear panel, too. Then mount the circuit board in the bottom of the box (if a board was used) with ½" or longer metal spacers. Use at least 4. Mount any other parts as necessary, and the mechanical construction is done.

Complete the wiring and you are home free. Refer to the schematic for details. I should warn you that it may be necessary to loosen or disassemble parts to wire them, so you might want to keep this in mind. Despite the best plans of mice and men, this problem crops up from time to time, so keep a screwdriver handy! Note the power supply.

Checkout

The moment of truth has come! You plug it in and there is a very good chance your project will show signs of life. Our power supply sure did! If so, congratulations on a good job! If not, you'll find a carefully built project much easier to troubleshoot than a haywire rig with a maze of carelessly laid out wires and components. You really gain with a properly built project; it is more likely to work, it is easier to service, and it looks a heck of a lot better to boot! Isn't it about time you got on the bandwagon?■

autopatch to fail due to user abuse. Since that time, ACK has taken a few steps in its evolution, including a frequency change to make way for the Baja repeater. Now, with the formation of the Marina Repeater Association to sponsor it, it has come up with a new objective as well.

While the prime objective is to provide the aforementioned type of communication, I foresee another important aspect to both ACK and MRA, that of being in the right place at the right time should an emergency on water manifest itself. By its very nature, the organization will be composed of amateurs who are adept at the many aspects of seamanship and will have a goodly number of vessels as part of its flotilla. Should an emergency requiring instant communication manifest itself, this group will be in a position to provide it, as well as handle other aspects of such situations. Again, it's skilled amateur operators adding another direction to amateur relay communication – another repeater with a purpose.

Now, as if all that were not enough, there is still one more important aspect to MRA, according to organization President Al Ezor W6QOG and its Vice President Bill Hawley W6ZRZ. MRA also intends to publicize amateur radio as a communications agent augmenting the pleasure of boating through various boating magazines and thereby interesting would-be amateurs in taking that all important first step. In the LA area, it plans to operate and sponsor the necessary classes to provide this training, which could result in a goodly number of new combination amateur radio/pleasure boating enthusiasts.

So, if you are planning to sail the Pacific coast between Oceanside and Ventura, keep an ear on .205 for the ID that reads WR6ACK. It may have been there for a long time, but now that ID holds a whole new meaning. For more information about this project, contact the Marina Repeater Association, PO Box 9894, Marina Del Rey, California 90291.

A few months back, *73* published a letter to the editor from a Northern California FMer directed toward us about the night to day differences between FM up North and that which we practice down here in the Southland. Is there that much of a difference between North and South? What is FM relay operation like in the Bay Area? Next month, Looking West takes a drive to San Francisco to tell you first hand all about it. See you then.

You Already Have an Atomic Frequency Standard

-- here's how to use it

B.F. Jacoby WD8ASL
88 W. Frankfort
Columbus OH 43206

Whenever a frequency standard is brought up, usually the discussion turns to the National Bureau of Standards' shortwave broadcasts on station WWV, but using these transmissions at any distance from Fort Collins, Colorado, where the transmitter is located, is difficult when reception is poor.

If you service CB radio equipment, commercial transmitters or amateur radio gear, an accurate means of measuring frequency is essential. If you are an experimenter or radio amateur who has a frequency counter, perhaps you have either not calibrated it or let its calibration slip because you did not realize that an atomic frequency standard was as close as your color television receiver.

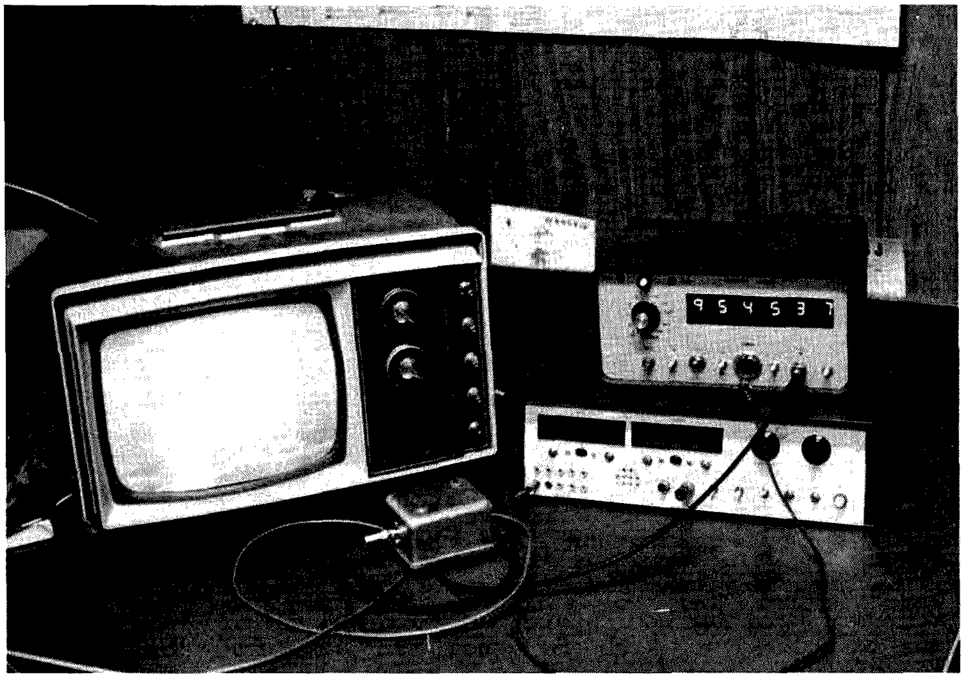
For some time now, NBS has been pushing the color TV burst frequency as a method of frequency dissemination, and once you use the system it will become apparent that it is both very accurate and inexpensive to implement.

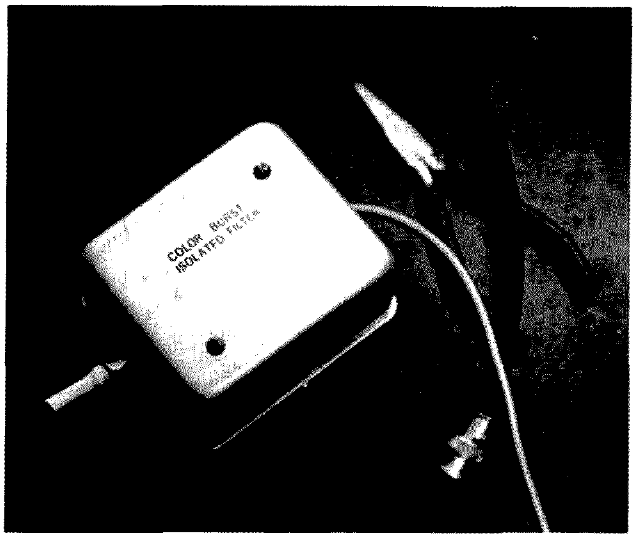
The basic idea is that all three major TV networks use atomic oscillators to produce the 3.57954545454 MHz color subcarrier frequency which is used to code and decode the color information in the video signal. This subcarrier frequency, or more exactly a piece of it, is broadcast with the video which is then used by the color receiver to regenerate a continuous carrier in the set for decoding purposes. The continuous frequency generated by the set is locked in frequency and phase to the transmitted piece of carrier or "color burst" as it is called, which thus produces an exact replica of the output of the network's atomic oscillator. While there may be minor phase shifts due to path length changes from network switching, the frequency stability is basically that of the generating source.

Thus, your access to an atomic frequency standard involves two simple steps:

1. Bringing the color burst frequency out of a TV and into your counter.
2. Waiting for a network program to come on. (Local stations use crystal oscillators which, while good, can be a couple of Hertz off frequency.)

The tapping of the color burst frequency in your set may take a little imagination, since each set is a little different. Receiver subcarrier regeneration systems fall into two broad categories: phase locked oscillators and ringing tuned circuits. To get into the right territory, look for the color burst crystal on your set's schematic diagram. Examine the circuit around the crystal to determine which type of system you have. If the crystal is an oscillator, then you have the phase locked type and it is the *output* of that oscillator





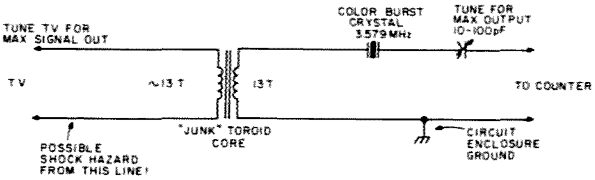


Fig. 1. Color burst isolator and filter.

that you want to bring out of the set. If the signal seems to pass through the crystal as a filter, then you have the "ringing" system and it is the output of the amplifier stage following the crystal that you should tap. Do not try to take an output from the crystal itself, as this can lower its Q and could stop oscillations altogether.

In either case, look for a good low impedance output point. Careful probing about with a scope should turn up a nice clean waveform you can use. Some set schematics have waveform pictures that can often be helpful clues. A word of caution is needed to remind you that many portable receivers have no power transformer, so the chassis could be 115 volts *hot!*

For this reason I have used the circuit of Fig. 1 on my portable set. The toroid transformer isolates the set from the line, and I have included an additional color burst crystal to peak the waveform into nice clean sine wave and filter noise pulses. This circuit easily drives my counter, which is not particularly sensitive. You may find that the "tint," "color" or "fine tuning" controls on the set, as well as the trimmer on the isolator circuit, may need to be used to peak your output waveform.

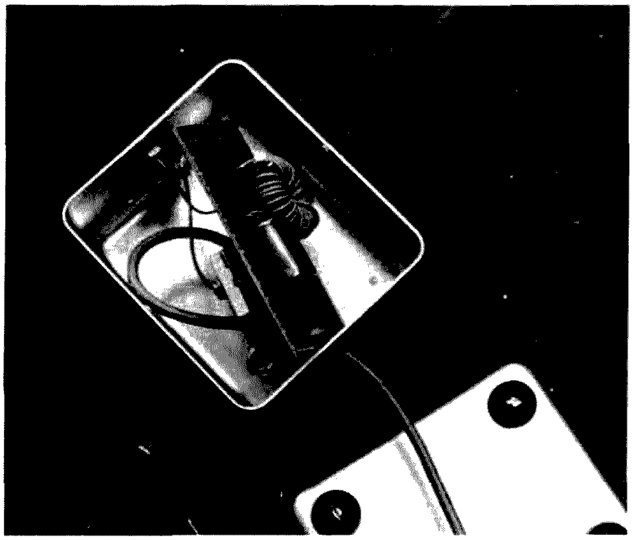
I've found that the tap-off circuitry tends to affect color reception, so you may want to have a jack to remove your output circuit when you are not using the set for calibration purposes. An alternative is to only use the set as a frequency standard. This may sound expensive, but my little set was free! It lost one of its colors in the picture tube and was deemed not worth fixing by the owner. This is a very common occurrence. Since you really need only one color to tell if a program is network (you could probably get by with just sound), so long as the color burst section is working, you have your atomic standard.

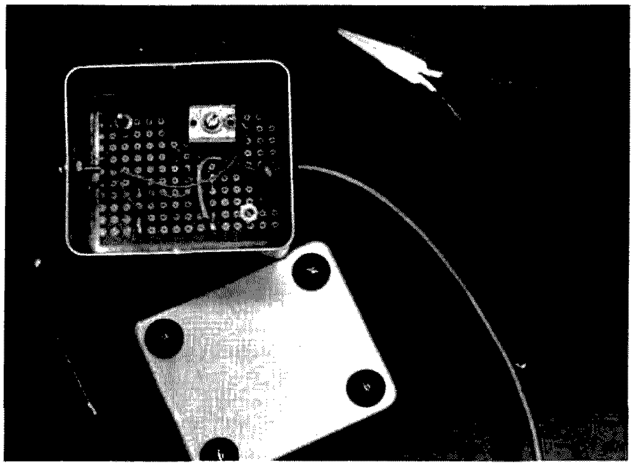
My home-built counter has a timebase that can be set as long as 100 seconds, which means that the counter, when adjusted, can read color burst frequencies to .01 Hz (or has an accuracy of .1 Hz at CB frequencies or .4 Hz at 2 meters). If your counter reads with a 1 second timebase, you can only set it to 1 Hz at color burst frequencies, giving you an accuracy of 10 Hz at CB and 40 Hz at 2 meters when calibrated.[1]

To calibrate the timebase oscillator on your counter, just feed the color burst frequency from the set into your counter and read its frequency with your maximum resolution setting. Now adjust your timebase oscillator trimmer until the display reads 3,579,545.35 Hz. The reason for the .35 Hz rather than the "ideal" .45 Hz is that all network frequencies are slightly offset due to a change in the international frequency standard after the oscillators were installed. You should measure with a good clear stretch of network programming and look out for commercials that may be local. Greatest timebase accuracy is attained when your counter is left on continuously, and in any event you should remember to allow a good warm-up period before calibration.

While the network frequencies have been 3,579,545.35 Hz for years, if you really want to stay on top of this situation you can subscribe to the NBS monthly time and frequency services bulletin, which lists the exact offsets for each network on a weekly basis. It is free on request, the only

[1] Notice that if you use the 15,734 Hz sweep frequency rather than the 3.579 MHz color burst to set your timebase, an error of reading ±1 Hz translates to an error of ±9000 Hz for 2m.





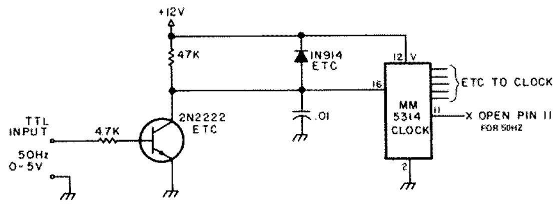


Fig. 2. Driving clock chip from timebase TTL output.

"cost" being a questionnaire they ask you to fill out about once a year asking which NBS service you use (WWV, TV data, etc.), how often, and why (ham radio, CB service, hobby, etc.). With the bulletin, great accuracy can easily be achieved. Those of us with clock and frequency standard hobbies have found the TV system to be a tremendous boon to obtaining synchronization of our secondary standards with little effort or expense. For extreme precision, a beat-frequency method can be used (but it is more complicated than the direct count method described here).

If you choose to leave your counter running continuously, you may wish to consider dividing your timebase to 50 Hz and building one of the numerous clock kits available today. Set your digital clock chip to run from 50 Hz, and feed the timebase signal into the circuit where it previously was connected to the power transformer. (The 60 Hz line is still used for power.) The simple interface circuit of Fig. 2 is an example that has worked quite well with the popular MM5314 clock chip.

The combination thus will give you a laboratory-accurate frequency meter and standard time source for your bench or radio shack. ■

Give the Hamburglar Heart Failure

-- car alarm system

With the theft rate of ham rigs on the rise, an alarm system should be installed by anyone who wants to protect his car and rig. Although an alarm system won't keep thieves from breaking into your car, it does make it much more difficult to do so unnoticed. After looking at the many, many alarms on the market, and their terrific prices, I decided that there must be a better and cheaper way. Many articles have pointed out the need for a "different" sounding alarm such as a bell, siren or similar device. But, for the money, the automobile horn is still hard to beat. After all, every car has one.

CMOS integrated circuits are a natural choice for use in automobile intrusion alarm systems due to their extremely low power dissipation. A sophisticated alarm circuit has been designed around two CMOS packages incorporating multiple time delays. The alarm circuit is armed by a hidden switch located inside the car. This design uses delay times to advantage. There is a delay from the time the operator turns on the alarm to when it actually is armed. There is also a delay from the time the intruder opens the door to when the alarm is actually sounded (this allows the operator to disable the alarm). In addition, there is a fixed time when the alarm is actually sounded, thus not running down the car battery more than is necessary. When the alarm is finished sounding, the circuit automatically resets itself, ready for another intrusion. In order to use the car horn as an alarm device, I decided to pulse it at a rate of 60 times per minute. This way people will not confuse it with a stuck horn. The circuit can either drive a relay, which in turn drives the horn relay, or it can drive a power transistor. The method depends on how much current the horn relay draws. The door switches are used as intruder sensing switches; other switches may be added on the hood or the trunk as considered necessary. All of the time delays are adjustable by changing several resistor values.

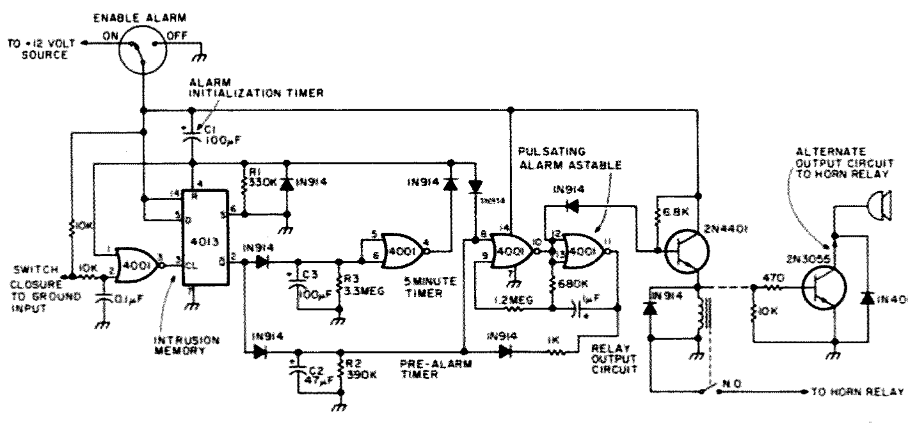

Fig. 1. This CMOS alarm circuit uses only two integrated circuits, yet provides a high degree of flexibility in its use. Delay times are provided to aid in the arming and disarming of the alarm. Once the pulsating alarm is sounded, it resets itself automatically after several minutes. $C_1 = 2C_2$; R_1C_1 – initialization reset timer (30 sec); R_2C_2 – pre-alarm timer (15 sec); R_3C_3 – alarm sounding timer (300 sec); ground 8, 9, 10, 11 on 4013.

Fig. 1 shows the schematic of the alarm using a quad NOR gate and a D flip-flop. The input to the alarm is taken from the door switches which control the dome light. When the doors are opened, these switches short to ground. The input signal to the alarm is normally 12 volts and goes to ground when the doors are opened. The driver enables the alarm by a hidden SPDT switch which connects 12 volts to the circuitry. Resistor-capacitor combination R_1C_1 develops a reset command signal to the intrusion memory when the alarm is enabled. This time delay permits the driver and passengers to exit the automobile prior to the arming of the flip-flop. Once the reset time delay expires, the flip-flop is ready to detect a switch closure to ground at the input. Once a closure to ground occurs, a positive going signal clocks the "D" flip-flop. Capacitors C_2 and C_3 were initially charged to 12 volts during the reset interval and they begin to discharge. R_2C_2 discharges below the NOR gate input threshold first, causing the 1 Hz astable oscillator to turn on. This astable oscillator is used to drive a small relay or transistor which turns on and off the horn relay in the car. R_3C_3 discharges below the NOR gate input at a much later time, generating a reset command to the intrusion memory. Thus, the complete process can repeat itself if another intrusion is detected.

The complete circuit can be built on a small vectorboard. IC sockets should be used for the CMOS circuits or a grounded tip soldering iron

should be used if soldered. Layout is not critical at all. For those who wish to duplicate the prototype, a 2" x 4" printed circuit board is being made available.[1] The circuit board can be mounted under the dash or under the seat. In one installation, the board was mounted in the trunk. The on-off switch for the alarm should be hidden, but within easy reach from the driver's seat. I would say where mine was hidden, but then it wouldn't be hidden anymore! Most horns use a horn relay located either near the fuse box or near the horn. The relay normally requires a switch closure to ground to sound the horn. If this is the case, then the transistor or relay output from the PC card can be used to connect to the horn relay. Since only four wires are needed to connect this alarm circuit, installation is very easy.

When the driver enters the car, the alarm is turned off, but will be initialized instantly if turned on again. In practice, a time delay of 30 seconds was chosen for the R_1C_1 time constant. R_2C_2 was chosen to be 15 seconds and R_3C_3 is 300 seconds. Either a relay or NPN transistor may be used to trigger the horn relay in the car, depending on how much current must be controlled. Since only two CMOS ICs are used, the circuits will easily fit on a small circuit board and mount under the dash. If the trunk or hood switch is paralleled with door switches, then it too will trip the alarm.

It is comforting to know that your car is being protected against intrusion. Since the alarm is controlled from the inside of the car, it is much more secure from intrusion. ■

---

[1] A 2" x 4" single-sided printed circuit board is available from I/O Engineering, 9503 Gambel's Quail, Austin TX 78758. Drilled $4.75; undrilled $3.75. Postpaid USA.

Contest Special Keyer

- - has short but adequate memory

Due to requests for the circuit of my keyer, displayed at the club home brew night, I decided to present the circuit, as well as a technical description, for those who might want to add it to their own setups.

The keyer portion is of straightforward TTL design.

Reprinted from *The Link*, Bulletin of the Buffalo Amateur Radio Repeater Association, Inc., May, 1975.

The clock, Z1, is an NE555 timer because of its stability, low cost, speed range and ease of operation. My keyer ranged from 5 to 35 wpm. Flip flops Z2a and Z2b form a counter in which the clock pulses are counted to provide dits and dahs with spaces. Z3a combines the outputs of the flip flops and Z3b inverts this. The diodes connected to the paddles provide self-completing dits and dahs.

Now the memory/control section. ICs Z4 and Z5 are two 4 bit binary counters which act as the "addressing" for the memory, composed of Z7 and Z8. Flip flop Z6 is the memory control. The clock from the keyer is gated with the control flip flop at Z3d to form the clock for Z4. This automatically stops the memory from writing over data just read in from the keyer. The LED gives a visual indication of the state of the control flip flop, telling you that the thing is through. The input to the memory comes from the keyer section. Gate Z3c combines the outputs from the keyer and the memory, allowing you to store and send over the air at the same time. The output of that gate keys a high voltage transistor, which should key any grid-blocked keyed rig. The control output is used to turn the clock on and off in the keyer.

Here's some information on the memory ICs used in the keyer. The 1101 is a static 256 x 1 bit random access memory (RAM). A dit takes 2 bits (dit-space), a dah takes 4 bits, and a space takes 3 bits. The total number of bits you can store is 255. To program this keyer, all you have to do is choose and switch the memory into *write* mode. Hit the *start* button and send the message on the keyer paddles. To send it back, change the mode switch and hit the *start* button. *Reset* will clear the address counter so you can start over if you goof. The address counter counts clock pulses and increments on the negative edges of them. Changing the message takes as long as it takes you to resend it.

This keyer works great, and I use it to send all my CQs and to ID the station when on RTTY. To those who build it, I wish you luck and much success.■

The Chintzy 12

- - a junk box wonder

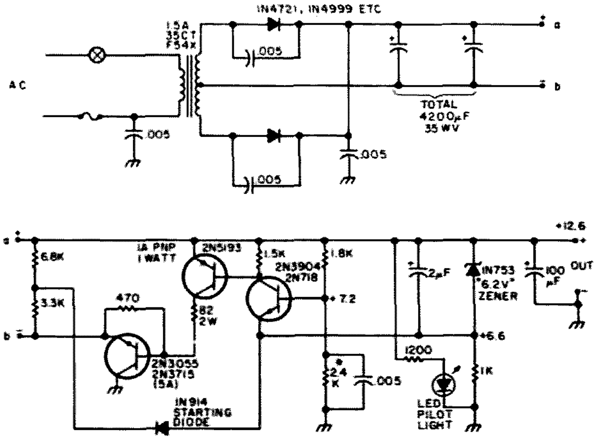

*Fig. 1. 3 A regulated supply (12.6 V). (a) Rectifier. (b) Regulator. The capacitor on the output is a tantalum slug type, of any value over 10 uF. The 3 A unit will carry a typical 10 or 15 Watt 2m transceiver. The 82 Ohm resistor constitutes the short circuit protection. *Adjust to set output voltage.*

This *is* a "how-to-build-it" article, but it also includes some hints in the "how-to-select-parts" area.

The problem with most "how-to" articles is that nobody ever has exactly the right parts. That's what keeps the kit business going. However, assuming that you do have some parts, how do you find out if they are appropriate? If you can find a suitable transformer (mine is sufficient for the cycles you may encounter outside the U.S.) and enough filter capacitance, the rest is sort of flexible.

I built my FM power supply inside a 4" x 8" x 2" aluminum chassis. Getting the transformer into the 2" dimension was a tight squeeze; 2½" would have been better, and 5" x 10" x 3" would have been spacious. The cord, switch, LED pilot light, output socket, fuseholder and the T0-3 power transistor went on one 2" x 4" end, leaving five faces blank. Inside, after finding room for two surplus electrolytic capacitors and the transformer, I wired the circuit on a couple of Cinch-Jones 2012 terminal strips. No sweat; no PC board. Save that jazz for complicated circuits!

Using a bigger transformer or more (thousands of) microfarads could only improve things. The power transistor was bolted directly to ground and the aluminum box provided adequate cooling. If you use a steel chassis, however, you may need some sort of heat sink, but remember that a silicon transistor will work all right even when its case is uncomfortably hot.

Fig. 1 shows the schematic of the 12 V supply. The transformer is nominally 35 V at 1.5 Amps, center-tapped. It weighs about one kilogram. An 18 V, 2.5 Amp unit of about the same weight and size, used with a bridge rectifier, would probably be satisfactory. I wouldn't try to use a 12 V transformer, as there isn't enough reserve for low line voltage. Instructions on checking out the alternative transformer you have on hand are given later in this article.

With the F-54X at a line voltage of only 100 V, the supply put out 3 Amps before losing regulation; at 105 line volts, 4 Amps; at 110 V and up, 5 Amps. For continuous service, two Amps is probably the limit, but since FM transceivers spend most of the time on receive, the low current works OK. The above figures are for 12.6 V out. For higher outputs, the transmit power will increase, but the current capability at any particular

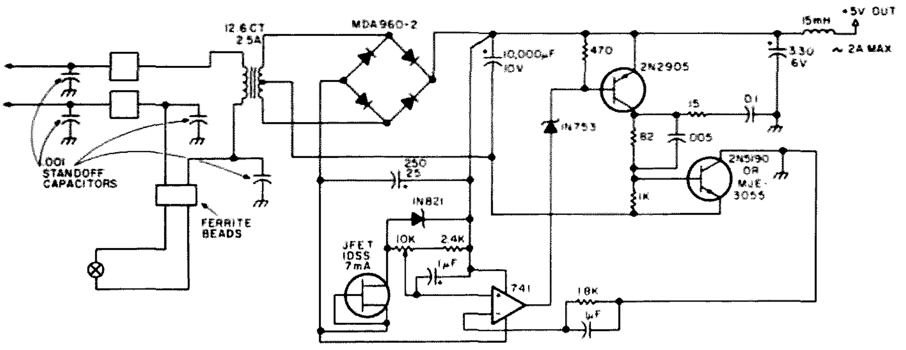

Fig. 2.

primary voltage will be less.

Each diode specified is rated for 300 Amps surge, 3 Amps average and will stand a short circuit long enough for the primary fuse to blow. No heat sinking is needed.

The filter capacitors may see more than 30 V, so you need capacitors rated at either 35 working volts or 25 working volts/40 V surge rated. They should have at least 2000 uF per Amp of rated load (more is better).

The pass transistor I used was a 2N3715 (similar to a 2N3055). The plastic MJE 3055 (or any one of the many T0-3 size silicon NPN power transistors) should be satisfactory.

Although the regulator circuit is simple, it continues working down to less than a volt between input and output – this is unusual. To keep the voltage drop down, the pass transistor is driven from the regulated output voltage, but this means that a separate starting circuit (two resistors and a diode of no particular type) is needed to turn things on initially. Once the starting diode has disconnected (during operation, its cathode is more positive than its anode), the regulator is unaffected by the magnitude of the unregulated input voltage – which is why it wouldn't start without the extra circuit.

Multistage regulators may oscillate. Stabilize this one by putting 10 uF or more (tantalum type preferred) on the output. I used a CS13AE 101K (100 uF, 20 V), because I had a lot of them.

The PNP driver could probably be a 2N2905, but the 1 Amp plastic power transistor (2N4918) I used is harder to blow out and has good gain down to 1 mA. I mounted it inside the chassis with a 4-40 metal screw using the mica washer provided. The 82 Ohm, 2 Watt resistor protects both the transistor and the power supply in the event of a short on the output. If you use higher resistances, you'll get a lower maximum base drive to the pass transistor and less short circuit current.

Depending on the actual voltage of your reference (zener) diode, you may have to adjust the voltage divider in the base of the NPN amplifier. I prefer setting things up with a soldering iron and putting a high resistance across one or the other divider resistor. In this case, I used a 24k Ohm across the 2.7k Ohm, because the 1N753 had only 5.9 V drop at 6 mA. If you put a 1000 Ohm pot between the two resistors, with the 2N3904 base hooked to the arm of the pot, it will still work. The capacitor still goes from base to ground.

Connect a capacitor across the reference diode. I've tried everything from 1 to 40 uF, so the size is not critical.

Place ceramic disc bypasses across the diodes (right across – with very short leads) to reduce hash picked up on AM broadcast sets. A number of commercial supplies, as well as automotive alternator diodes, can cause this sort of interference.

In wiring high current supplies, it is good practice to run wires from diodes and the power transformer directly to the big filter capacitors and then run additional wires from the capacitors to the regulator. Run the input leads together to keep the stray field down – those wires are carrying 10 Amp pulses. In a ham station, it is also smart to filter all leads for rf; audio rectification in a transmitter power supply can give some strange feedback.

A design-it-yourself program is as follows:

a. Measure the output voltage. In this case, given 12.6 V, I added 1 V for regulator variations and 15% for power line variation, for a total of 15.6 V minimum instantaneous (dc minus ripple) input to the regulator at 115 V.

b. Measure the load current and calculate ripple. For 2 Amps, given 4200 uF (that was what I had), peak-to-peak voltage = 2 x 1/120 x 1,000,000/4299 = 3.97. On that basis, required dc is 17.6 V and rectifier load R is 8.8 Ohms.

c. Using a VOM, check the power transformer for the following values: line voltage = 115 V; secondary, no-load voltage = 39 V (10% higher than nominal); ratio of primary to half secondary = 5.9; dc resistance of primary = 9 Ohms. Primary resistance reflected into half secondary is then 9 divided by $(5.9)^2$ = 0.26 Ohm. Measured secondary resistance = 1.1 Ohm; half of that = 0.55 Ohm. Thus the series resistance of the transformer is effectively R_S = 0.55 + 0.26 = 0.81 Ohm. At 20 Amps instantaneous, the diodes I picked have a 1.2 V drop with a slope equal to 0.01 Ohm at that point for a total of 0.82 Ohm.

Referring to the curves,* I put in the ratio R_S/R = 0.81/8.8 = 0.093 and C x R x 2π f = 13 with a result of 20.9 V. From this, I deducted the 1.2 V dropped in the diodes to get 19.7 V dc. Since I needed 17.6 V, this worked, leaving an extra ten percent to take care of transformer heating (the resistance increases when the windings get hot) and nonsinusoidal power line waveforms.

In applications where noise and ripple requirements are moderate, a grounded collector pass transistor is often convenient. Fig. 2 shows the 5 V supply I built for a receiver frequency counter that used LED readouts. The display added a strobed 1 Amp load to the other drain, putting the requirements out of reach of the usual IC units. The circuit, as shown, fit the parts I had on hand and performed well enough down to below 90 V from the power line. I used a compensated reference diode, but a 1N753 will do as well. The FET current regulator (if you have one with I_{DSS} around 7.5 mA) is an improvement over a 1200 Ohm resistor, and of course a 741 is one of the best op amps you can buy for forty cents. The driver and pass transistor are treated like the equivalent parts of the 12 V regulator. (Refer to previous discussion.) The power transformer was a Triad F-26X, 12.6 CT at 2.5 Amps. The 10,000 uF filter is no bigger than necessary. ■

*Originally from O. H. Schade, *PIRE*, July, 1943, but can also be found in the *Radiotron Designer's Handbook* and, with some modification, on p. 108 of the 1976 *Radio Amateur's Handbook*.

You Can Sound Better with Speech Pre-emphasis

-- a simple circuit which will work wonders

73 Magazine *Staff*

This article describes a very useful single transistor stage peaking filter together with a low noise, rf protected preamplifier stage. One of the main features of the circuit is that the overall gain of the filter stage remains essentially constant except at the frequency which is to be peaked. The peaked frequency can be continuously increased in gain up to about 20 dB as compared to the overall frequency response (about 200 to 4000 Hz).

The main application of this filter is to improve speech intelligibility for any mode of modulation, particularly for those of us who tend to be rather bass-heavy. Simple high pass filters can, of course, remove bass frequencies, but that is all they can do. A peaking filter, on the other hand, can be used to emphasize the so-called "presence" effect as hi-fi enthusiasts know it. This means a soft peak in the overall frequency response of a system around 1500-2000 Hz, which adds a great deal to the improvement of speech intelligibility. By choosing a good communications type microphone which normally attenuates frequencies below 300 Hz, and with the aid of a peaking filter, most base-heavy amateurs can achieve a good, solid, communications speech response without sounding unnatural or distorted. The variable gain feature of the filter at the peaking frequency allows one to adjust the filter to suit individual voice characteristics.

A secondary use of the peaking filter circuit in receiver application is as an audio-type CW or SSB filter. Admittedly, there are sharper, single frequency IC designs available for such filters using also only RC components, but the filter design to be shown can be made both variable in frequency (over a narrow range) and variable in peaking amplitude. Thus, by connecting in series two such filter stages which tune 500-1500 Hz, one can peak a single audio frequency with both stages with sharper selectivity, or any one of two audio frequencies independently with variable gain, depending upon how QRM conditions vary.

The circuit of the combined preamplifier and filter stage is shown in Fig. 1. The microphone preamplifier is especially suited for low to medium impedance dynamic microphones, but it will work well with almost any impedance microphone. The ferrite beads, a low Q 1 mF electrolytic coupling capacitor, the 10k resistor and the 200 pF base to emitter bypass in the input stage all are designed to keep rf out. Assuming the preamplifier and filter stage are mounted in a separate shielded enclosure, no rf problems should be encountered. The 200 pF base to emitter bypass is a nominal value. For 2 meter usage, a 100 pF with very short leads is better. For 80 meters, the capacitance might be increased up to 330 or 470 pF. The rest of the preamplifier stage is designed for low noise amplification with a gradual roll-off below 200 Hz and above 4000 Hz. If a still sharper roll-off is desired on the low frequency end, try reducing in value the 1 mF input coupling capacitor to the filter stage. But, keep the

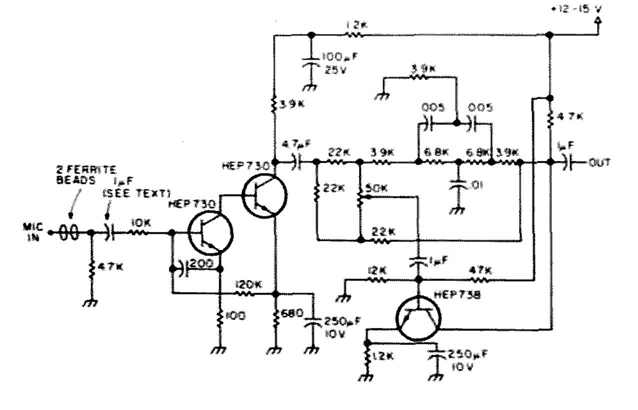

Fig. 1. Circuit of the complete unit. First two stages are a low noise preamp followed by a constant gain peaking stage.

input coupling capacitor an *electrolytic* type. The low Q of such type capacitors offers better protection against rf feedback effects than disc ceramic or paper types.

The HEP 738 peaking filter stage makes use of a parallel T network (R1-R3 and C1-C3) as its primary element with the rest of the circuitry arranged around it to provide a feedback arrangement for peaking while the overall stage gain remains essentially constant. The values shown will produce a peaking frequency of about 1500-2000 Hz. The exact peaking frequency for transmitting application does not seem to be too important if it fails within this range. Thus, nominal 10% tolerance components for the network elements will suffice. If one wants to use the filter stage as a selective filter for receiving purposes, component tolerances should be held to 5% or less. The peaking frequency can be raised or lowered as desired by adjustment of the values in the basic T network. The formula for the peaking frequency is equal to:

$$\frac{1}{2\pi \times C1 \times R2}$$

where R2 equals R3, R1 is half the value, C1 equals C3, and C2 is twice the value.

The 50k peaking frequency amplitude potentiometer will allow adjustment from a flat response (microphone plus preamplifier shaped response) to one where the approximate 1500-2000 Hz range is boosted from 0-20 dB. The determination of how much peaking effect to use is necessarily a subjective one. Probably the best method to use is to make a tape recording using good quality equipment at different peaking levels and request on-the-air comments. Make the receiving operator, however, reduce the af or rf gain on his receiver to a level where you are just intelligible under ordinary modulation conditions. The use and proper adjustment of the filter will not make the difference between a marginal and a solid QSO, but in most cases it will definitely add a noticeable degree of intelligibility and communications "punch" to the audio on any phone transmission. The reason why? There is no simple answer to this, although textbooks such as *Reference Data for Radio Engineers*, Fifth Edition, Chapter 35, will provide all sorts of interesting data on human hearing versus frequency of transmission. Perhaps one of the most interesting charts is that shown in simplified form in Fig. 2. It shows equal loudness contours versus intensity for different frequencies. The curve is generalized, of course, because of the variations in hearing with age, etc. But notice the marked sensitivity of the ear around 2000 Hz. Raising the level of sound transmission at this frequency, where the normal ear is most sensitive, will create the effect of a louder and more intelligible signal. ■

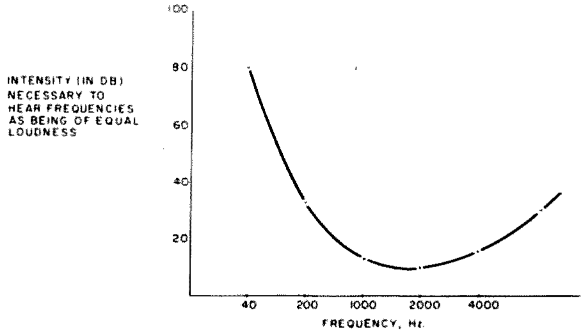

Fig. 2. The reason why boosting the frequencies around 1500-2000 Hz gives the effect of better intelligibility to voice communication circuits.

BE MY GUEST
visiting views from around the globe

from page 11

the transmitters, the Scandinavian countries were especially hard hit by the noise with their radio communications being almost completely wiped out. They poured a continuous stream of complaints into the Soviet Union.

A source at the State Department called the Soviet statement "encouraging," but declined to speculate on the reason for it. He said that despite the admission, the formal complaint was sent.

Articles about the noise appeared in newspapers throughout the world. Government sources were surprised about the great degree of publicity that was generated.

The "Big Noise" is only the tip of the iceberg regarding interference. FCC files currently contain over 300 pending cases of alleged international interference.

Whether the noise will be gone for good is a fact that remains to be seen. Propagation study or transmitter test, the foibles of international politics are involved. We may not have heard the end yet.

Associate Editor

HF-Texas Style

As reported last month, a series of raids in the Baltimore area late in October netted over sixty-five thousand dollars worth of radio equipment. The engineer-in-charge of the Baltimore FCC office, Robert Mroz, told *73* that, of 19 HFers raided, criminal charges were brought against 18 by the US Attorney's office. Each was charged with between 9 and 33 counts of illegal use of radio transmitters, punishable by fines of up to $500 per day, per violation. One of those involved was a General class ham. Administrative action has been taken against his license.

Early in December, a single raid in Delaware resulted in the confiscation of HF equipment worth $1200, as well as a CB unit that was illegally modified for 40 channel use. FCC engineer Mroz said the office of the US Attorney is helping the Commission catch the illegal operators through cooperation with FCC authorities. In the case of the Delaware raid, a search and seizure order was issued the same day the HFer was located by an FCC monitoring station.

In mid-November, two FCC agents, six US marshals, and ten police officers raided a home in Houston TX. They confiscated 20 linear amplifiers ranging in power from 250 Watts to a *6000 Watt* homebuilt unit using television transmitter tubes. At press time, charges were pending against three men in connection with the raid. Houston engineer-in-charge Allan Kantrall said that it was believed that one of those facing charges was selling the linears to fellow HFers. He added that a group of neighbors applauded the confiscation, as television reception in the neighborhood had been disrupted.

Kantrall told *73* that the Houston office faces an extremely severe problem in dealing with illegal activity because the Texas area has the highest concentration of CBers in the country. The city of Houston has the greatest number of CB licenses of any city in the United States, according to the FCC. Kantrall said his "greatest headache" is the use of linears. A few years ago, power levels of one to two hundred Watts were common. But with the increase in activity, illegal operators have had to go to higher and higher power in an effort to drown one another out.

Along with the out-of-band activity and linears, the FCC engineer added there has been a huge increase in profanity and threats over the air, which has resulted in beatings, stabbings, shootings and even murder.

Kantrall hopes that a large public service effort on the part of the Houston office will help to educate the public about FCC enforcement operations and the results of illegal activity. In one recent case, FCC personnel spoke to a gathering of over 5000 CBers.

Despite a shortage of enforcement officials and monitoring equipment, FCC officials do not intend to let the illegal activity continue. Raids and prosecutions are expected to continue. In fact, after the recent raids in Baltimore, FCC engineer Mroz said that as of year's end there were "no HFers operating in the state of Maryland."

Are You Really Insured?

-- time to read the fine print

Amateur radio operators are familiar with Morse code, but how many have taken the time to learn the National Electrical Code (NEC)? The purpose of this article is to familiarize you with the provisions of the NEC and how they apply to the amateur radio station and to give you some common sense applications of these rules. Compliance with these rules, by the homeowner ham, could prevent the loss of both home and fire insurance. Many insurance policies contain the clause that, if fire occurs and the investigation shows NEC violations, benefits payable under the policy may be disallowed. Ignoring the insurance requirements, the NEC provides for a safe and efficient installation and should be given serious consideration by the ham.

ANTENNA SYSTEMS – GENERAL

Material

To comply fully with the NEC, the antenna must be comprised of hard-drawn copper, bronze, aluminum-alloy, copperclad steel, or other high strength, corrosion resistant material. Soft-drawn or medium-drawn copper may be used for lead-in conductors where the maximum span between points of support is *less* than 35 feet. Table 1 shows the required size of conductors for amateur receiving and transmitting antenna systems. As you can see, most spans will require at least number 14 wire.

Outdoor antennas and lead-in conductors (including vertical antennas and dipoles) shall be securely supported. The antenna must *not* be attached to any electrical service mast or pole (this includes utility and telephone poles). No antenna can be mounted on a pole or similar structure carrying electrical light or power cables of more than 250 volts. The antenna and its supports should be located far enough away from the various power lines that in the event that the antenna or support falls, contact with these power lines will be avoided.

To apply this rule for, for example, a 21 foot vertical, locate your antenna so that if you were to visualize it as the center of a circle with a radius of 21 feet, at no point in that circle would you find a power carrying cable. If you are able to find a clear 21 foot radius, you have found the best location for your mast.

A sturdy mount and enough guy wires to provide the necessary strength to withstand ice and wind loading conditions should be installed. The guy wires should be located well away from overhead conductors of electrical light and power circuits.

Avoidance of Contact With Other Conductors

Outdoor antenna and lead-in conductors from the antenna to a building should not cross over electric light or power circuits and should be routed well away from these power lines to preclude accidental contact. If proximity to power service conductors carrying *less* than 250 volts cannot be avoided, there must be at least two (2) feet of clearance.

The code recommends that these antenna conductors be installed in such a manner that they neither cross *over* nor pass *under* power carrying conductors. The reasoning is sound: In the event that your conductor was above the power line and fell, it would short the power cable and impress high voltages into your antenna system and allied equipment. Conversely, if your cable was below the power line and it fell, the power conductor would short to your system and again impress a voltage on your system, causing a safety hazard.

Splices

Any and all splices on the span should be made with approved splicing devices and offer a firm mechanical joint. Soldering may ordinarily be expected to weaken the conductor. One method is to use an antenna insulator (as shown in Fig. 1) and jumper between the two sides. This will provide a firm mechanical connection as well as an

Elliott S. Kanter W9KXJ
3242 W. Hollywood Ave.
Chicago IL 60659

electrical path. Several layers of electrical insulating tape may be applied to the splice if desired.

Grounding

The NEC requires that masts and supporting structures be permanently and effectively grounded with no splice or connections made to the ground wire. The easiest method of providing a good ground is taken from the telephone company and requires that a conductor of at least AWG 12 (copper) or AWG 8 (aluminum) be run from the mast to the cold waterpipe. The lawn sprinkler faucet located on the outside of many homes is a good termination point for our ground.

In order to use this system, you must first verify that there is a direct metallic path through the cold water pipes. A visual inspection will show you if you have metal or plastic pipes. Assuming that you have metal pipes, follow them to the water meter.

Use your ohmmeter to verify an electrical path through your water meter. This is necessary because certain water meters have an insulated coupling. If you do not have a metallic path through the meter, refer to Fig. 2 and sand or file an area at least two inches wide around the pipes. Coat this shiny area liberally with Vaseline and install two grounding clamps (one on each side of the meter). Run a conductor of at least AWG 14 between the two clamps and connect the ends of this wire to the clamps. You have now made a metallic path, and can use the outside faucet fitting for your ground termination point. Prepare this pipe in the same manner as you prepared your water pipe bridge and fasten your ground wire securely to the ground clamp.

Alternatively (in the case of plastic water pipe), drive a ground rod into the ground and connect the ground wire firmly to the rod. Because of the differences in soil resistance, the water pipe method of grounding is recommended wherever feasible.

Lead-in Conductors

Lead-in conductors for amateur radio stations shall be at least as large as the antenna conductor shown in Table 1. For example, a long-wire antenna fed with a single wire should carry the same sized conductor for the antenna and the lead-in (150 foot antenna – AWG 14).

Material	Minimum Size of Conductors When Maximum Open Span Length is Less than 150 feet	Over 150 feet
Hard-drawn Copper	14	10
Copperclad steel, bronze, or other high strength material	14	12

Table 1. Amateur station antenna conductors.

CONNECTIONS TO BUILDING AND SYSTEM

Clearance on Buildings

The antenna conductors, if attached to the building, should be firmly mounted clear of the surface. These standoff insulators must provide three inches of space between the wall of the building and the conductor. In the case of a permanently and effectively grounded wire enclosed in a continuous shield (coax), the three-inch requirement is negated.

Entrance to a Building

Except in the case of coaxial feedlines, all lead-ins should enter the building by one of the following methods:

1. Through a rigid, noncombustible insulating tube or bushing.
2. Through an opening provided for that purpose in which the entrance conductors are firmly secured to provide a clearance of at least two inches.
3. Through a drilled window pane.

Safety and Protection

Protection Against Contact: Each conductor of the outdoor antenna should be located in such a manner that accidental contact with them is difficult or impossible.

Lightning Arrestors – Transmitting Stations: Each conductor of an outdoor antenna should be provided with some method of static charge drain (either a switch or lightning arrestor). The only exceptions to this requirement are as follows:

1. Where the conductor is protected in a continuous metallic shield (coax) and is permanently and effectively grounded.
2. Where the antenna is permanently and effectively grounded.

System Grounding Requirements

Grounding systems for the transmitter and the receiver follow the same basic rules set forth in the section on antenna grounding. However, the size of the conductor must not be less than AWG 10 (copper) or AWG 8 (aluminum).

Interior Installations

It is advisable to have a separate power line for radio transmitting equipment. Ideally this should be run in separate conduit or Bx (consult local electrical code) and separated from the normal house power wiring by at least four inches. This circuit should be fused and the conductors capable of carrying the rated current load. Past experience in installations has shown that if one takes the entire current requirement and allows about a 25% safety factor for future expansion, this total figure will give a much more realistic guideline to the choice of conductors. For example, if we calculate that our total current drain is 15 Amps and we allow an additional 5 Amps for future expansion, we arrive at a figure of 20 Amps. The wire table shows that the best choice of wire size for this load would be AWG 12. Fusing should also allow for this current level but should not exceed the current carrying capacity of the wire chosen.

Transmitters – General

The transmitter should be enclosed in a metal frame and have a barrier (either panel or mesh) separating the inner works from external contact. (The transmitter cabinet fulfills this requirement.)

All external metallic handles and controls accessible to operating personnel should be effectively grounded.

No circuit in excess of 150 volts should have any controls or parts which carry this voltage exposed.

All access doors should be provided with interlock switches which will disconnect voltages in excess of 350 volts when these doors are opened.

SUMMARY

We have explored the code and seen that many of its requirements are founded on safety. It would be wise to abide by the dictates of the NEC. This will increase the safety and efficiency of your operation. Using common sense, a grounding rod and interlocks on your transmitting equipment will help avoid injuries and enhance your enjoyment of amateur radio.

Before implementing these rules, check with your local electrical inspector and get a copy of your local electrical code. There may be some deviations from the NEC, and, in order to be safe and legal, you must be aware of all local as well as national electrical code requirements as they apply to amateur radio stations.

Remember, the code complying station is a safe station . . . so let's code it. ■

Getting a Patent--

Is It Really Worthwhile?

--how to do it, if you really want to

George A. H. Bonadio W2WLR
373 East Avenue
Watertown NY 13601

Because of the very nature of our amateur hobby, we have more inventors per banquet table than at any other conventions. Inventors bring up the idea of patents. Patents bring up thoughts of publications from the Commissioner of Patents, like: "Rules of Practice," "Answers to Questions Frequently Asked About Patents," "Patent Laws," "General Information Concerning Patents," "Office Consolidation of the Patent Act," "Guide for Patent Draftsmen," and so on, little of which I want to mention here.

Besides completing a course on patents and their management, I have seven patents, an eighth applied for, several abandoned, one infringed and the usuality of none producing an income.

What Is A Patent?

Your patent is a legal document proving that you first made public a "new and useful device, process or plant" and therefore can legally go to court and "start an action" against someone else who refuses to recognize your monopoly rights so granted. In this court action you are alone. The government will not help you.

Your patent (and its rights) is a thing which you can sell entirely, or in part, or license out under any kind of restrictions, or keep all to yourself. It lasts 17 years from its "date of issue."

What Does It Entitle Me To?

For 17 years, if you do not dispose of it, it entitles you to charge all the traffic will bear upon all those who will commercially use your patent. It lets you spend a fortune in each court "action." If you are "small" and it is "big," you can expect some legal rough-and-tumble action with it before the end of 17 years. You can sue up to triple damages on infringers, who will be ready for you. They may counter with a suit that proves that your patent is invalid, for some little oversight. Then you are entitled to pick up the heavy court costs.

How Do I Proceed?

Be sure that you have something which is "new and useful." Send $3.25 to the Superintendent of Documents, Washington, D.C. 20402, for a copy of "Patent Attorneys and Agents Available to Represent Inventors Before the U.S. Patent Office."

Find the nearest several patent attorneys, who do not advertise, and write or call each, asking, "Do you handle electronic patent applications for private inventors?" Do not use an attorney who discourages a preliminary visit by you.

You will have to trust this attorney in many facets. Be sure he has a good reputation. Inquire around. Ask him who he has worked for in the past and talk to them.

You cannot assay the market for your item by yourself. You are too biased. You must use friendly advice. I'll tell you now that it will be darker than your outlook. Companies spend heavily to introduce new items. Is yours worth it?

Is It Patentable?

A "search" by your attorney's agent in Washington will cost up to $100. It will pop up with patents back to the last century (which were better than your idea) or a diagram from the pages of *73 Magazine* which is completely unrelated, you point out.

I "invented" a terrific navigational device for the last 200 feet of a plane's descent onto a runway (using 7 kHz and 9 kHz whole field loops) only to find it had been "issued" the very day I "invented" it. (Yes, I'm good at ESP, giving demonstrations at conventions.) However, the real inventor has not gotten it onto the market. It is simple, foolproof, unobstructive, workable in a power dead plane, inexpensive, and on and on, but it expired in 1961, unused.

Is It Competitive?

If your invention costs more and does less, you are dead. If it costs less and does more, you still have only a fighting chance. It has to be much better on the market than what is there now, or you will not even get a hearing. Even if it is good, who is going to risk his present profits to see if the crazy consumers will do him much better on your item?

Who Will Market It?

A company with back orders now may tell you to go away. A weak company may tell you that it cannot afford the big risk to tool over to your invention. A speech compressor company doesn't care about your new antenna system.

Your best marketer is your own company, and the best patent is one developed for your own company to advance on from its present successful position.

Patents from outside a company are immediately suspect. They are not in line with plans. They can embarrass the company engineers. The claims may not be well-written for their uses.

Where Is A Patent Attorney?

He is on the other end of your phone or letter, or in court. If he does not go to court for his clients, he may not be able to help when you most need someone who understands all of your patent.

He is in there working with you on your selling or licensing agreement (in his office, not yours). Your regular lawyer is not very informed on patents. Patent laws are in a world by themselves.

If you cannot spare a thousand dollars and a hundred hours per patent application, don't start. There are filing fees, artist fees, attorney fees, and final fees, at least, on top of mail and phone and travel in business hours.

Less than one quarter of one percent of patents "issue" on the first "action" by the Patent Office "examiner." However, my Box Diagonal Antenna did, and this saved me, perhaps, $200 in additional fees. My attorney and I would have had to argue around the examiner's "action" with a new "response" material, if I could, or "abandon" the whole thing. Sorry, no refunds.

The attorney, if he is experienced in working for corporations, can do an excellent job for you. If he is an advertising attorney, he cannot show you that one half of one percent of his inventors have ever made a profit on any one of their patents. Most of the corporate patents are credited with netting $1, or more. Think about it.

What Do I Claim?

Your attorney will have to rewrite what you claim in language you can scarcely understand. What you display, but do not claim, is gone. What you claim, but which the examiner "disallows" or "rejects," is lost.

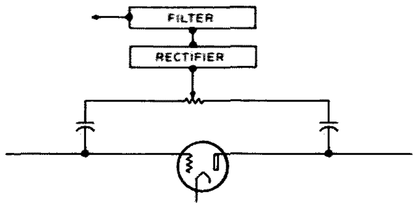

Fig. 1. The Bonadio Automatic Distortion Control, Patent #2,634,339. The tap position is at the null of detection, with distortion-free output. Any distortion will produce a detected signal at this setting, and can be used for automatically controlling the distortion level.

When your claims are long and have many conditions, they are "narrow" and cost more for attorney's fees than they are worth to you or anybody else.

The only test of a patent is in court, which you would rather not invite. A good patent is in a newer field, like electronics, rather than mechanics, and has no near misses in the "search," no near collisions with the "examiner's actions," has a few adjustments of the "claims" to satisfy the examiner, and covers all possible variations by an "omnibus claim," which covers the field like a tent.

How Secretive Must I Be?

Ask your patent attorney. On a simple patent, he may have you out hawking it after it has been filed for three months or, if it is a complicated patent, after six months from filing date. After you file an application, a later similar filing, by another inventor, produces an "interference." The later inventor must prove that he was "diligent" in getting his application filed, even while he must also show that he actually invented it, or "reduced it to practice" before you did. He's got troubles.

My fastest invention took months to prepare for filing, only 23 months in the Patent Office, and issued July 1, 1969. It had no extra "actions" and "responses," which could extend a few years its time while "pending."

After your patent attorney has notified you of your filing date and number, you must, in public, refer to your invention as "patent applied for," either by a note in the text or by putting that phrase on the item for sale, or you can lose your rights.

Later, after the examiner has allowed one or more claims, you must refer to it as "patent pending." Actually, you may obtain more claims many months later, and then "issue" six months or more after that.

As soon as you conceive it, or even before, you can contract to sell it, say, to your employer, as part of keeping your good job. Have your patent attorney do all the contract paper work, even if your company has its own patent attorney. Yours will earn his pay for you.

If it's a company patent, you may get a guaranteed first option on any job in the company for which you can qualify, during the life of the patent. You might extend this to your child, and even to your family, if the patent is valuable in keeping the company going. This type of payment can be a bigger reward than any cash outlays that the company can afford.

This department is where your patent attorney's talents will show up – trust him.

What's An Interference?

It's a signal that two minds are on the same idea and filed patent applications at nearly the same time. If you filed second, save your money. Abandon it right there.

If you filed first, and the other party is in a company which was planning to use it, you have a captured audience. Have your attorney contact them at once to see about improving the claims to satisfy them and to license the application to them the best way your attorney can.

What If My Claims Are Rejected?

Then you have wasted considerable time and money. Forget it. Abandon it. A true inventor has more good ideas than he can afford to try and probably has an application brewing at all times.

Should I File?

This question finally has to be answered. If you are working in, for, or with a company which will use the patent, by all means, yes. If you have a financial backer, whom you do not have to repay (by a contract approved by your patent attorney), again, yes. However, if you are like the 220 private inventors who attended an inventors' convention in Cleveland, who all agreed that none, representing about 400 patents, had made a profit on any one patent, the answer is no.

The typical private patent covers an invention which not enough people either need, want, will pay for, or will switch over to. This typical home invented patent does not fit in with any manufacturer's planned progression.

If your patent, like my Automatic Distortion Control (Patent #2,634,339), can be buried in a large electronic device, forget it as a private invention. I can show how I was invited by the military to sue for damages; they even gave me the contract numbers. Two manufacturers, whose names you know, have used the ADC. Possible royalties are not worth the tens of thousands of dollars I would have to risk to fight the cases.

The Bonadio Automatic

Distortion Control is the ultimate in electronic simplicity, a desirable patent trait. In Fig. 1 there is a blocking capacitor, or two; a bridging resistor between input and output of a tube, valve or transistor; a tap on that resistor leading to a detection unit, such as a diode; and a filter. Without distortion it detects no signal, the tap being at the null. As distortion increases, the null point moves away and useful output develops, which can be used to reduce both the gain and the distortion. For example, on a transistor radio it would hold the audio output to all the quality output possible, even following a dying battery down in output. Imagine all transistor radios with no audible distortion!

Unless you are a big manufacturer, you cannot police infringers on this size device. I can't. An infringement suit could cost me $40,000 if I lost, to say nothing of the years of anxiety involved. One's health has quite a value, too.

As long as a manufacturer knows that I cannot afford to sue him, he knows that he can use it without fear from the patent owner. He will never buy it from me under these conditions.

His only fear would be that I might put it into profitable use myself, and then be able to sue him. While this hope, on my part, is futile for my ADC, it could happen with something wholly covered by patents and harder to bury, such as my several antennas. However, he can see my operations and calculate my actions years in advance and prepare to negotiate, fight or abandon the device. He knows that no other manufacturer will be foolish enough to pay for what he, too, can have free, especially in a small device.

What's The Success Ratio?

Aiming to increase my success ratio, my latest patent applications and patents have been in units entirely covered by a patent, not just a small bit circuit in a huge monster assembly. Not only that, but they stand exposed outdoors – for all to see, instead of buried, as in the ADC.

I estimate my first antenna patent possibility of producing a profit at about one in 500! With the related second patent I probably improved my chances to one in 50. Now, with the third, a "continuing patent," I believe that my chances are as good as one in five! I have had some encouraging results on one more patentable advance on these. If it works out, some years from now I should be able to negotiate.

How Do I Negotiate?

You negotiate through your attorney, at about $25 per hour. You don't make a move without his approval. He will probably let you advertise to your heart's content after you have been filed for three months or more.

Your problem is to find someone who can be convinced that he cannot afford to ignore your patent – and to convince him of this fact. I found that antenna companies receive about a dozen offers a year. Compare this with the number of really new antennas on the market each year.

Nobody Wants Them?

I mailed 157 notices to antenna companies. Seven addresses were returned as "unknown." Five gave useless responses. Then I mailed a series of three hard hitting letters to 19 likely manufacturers. Four (a splendid response) inquired further. None want to test under the conditions I recommend.

Although I warned that my antenna "effects" happen only in the ionosphere, one turndown referred to a computer test and another to an all earth test range. No company has tried them in the ionosphere yet.

A small, friendly manufacturer, whom I phoned, told me that he could not sell his patents either, so he and his wife struggled for ten years and now are doing fine as a manufacturer. He suggested the same route for me.

Use Them Or Lose Them?

Because of the fast moving electronic advances, patents are generally estimated to have a 5 year profitable life, out of their 17 year legal life.

Like anything else, if you don't use them, you lose them, and I estimate that I have spent over 1,000 hours on these few.

What Should Be Done?

Don't become like the neurotic inventor, who produces a patent that only he could love and then spends the rest of his life wasting his time, money and health trying to force it on a world which won't have it.

Don't deprive your family of its needs in order to obtain a $1,000 patent. The odds are over 200 to one against getting your money back.

Don't expect a patent sales agent, to whom you are fair game, to sell your patent any better than you can, for his price. He doesn't sell 1% of his customers' patents.

Don't keep an invention buried until you can afford a patent. Name the circuit after yourself and sell a story about it to the editor. He will pay you for the story. If the circuit is continuously usable, you will have your name hung on it, and you will be immortal. That's better than an expensive dead patent which you might, helplessly, see infringed under another name (my ADC infringements were under two other descriptive names) after you paid for a patent to have your own name known.

Do ask the editor to spell your name right, like B-O-N-A-D-I-O's ADC. ■

Social Events

Annual Ham Auction, Sunday, March 20, 1977 at the Lucas County Recreation Center, Maumee (Toledo), Ohio. Auction, flea market, commercial displays and good eyeball QSOs. Time: 8 am to 5 pm. Admission: $2 advance, $2.50 after March 1, 1977 or at the door. Talk-in on 52-52 and all Toledo area repeaters. Send SASE, Toledo Mobile Radio Association, Inc., Box 7548, Oregon OH 43616.

COLUMBUS GA
APR 2-3

The Columbus, Georgia Hamfest will be held April 2 and 3, Palm Sunday weekend, at the Fine Arts Building at Fairgrounds, 9 am to 4 pm daily. Flea market, ham auction, prize drawing at 1:30 pm Sunday, talk-in 28/88, 3975 kHz, buffet dinner Sat. at 8 pm. For more information write K4JNL. Advance tickets: K3MTY/4, Rt 5, Box 750, Phenix City AL 36867.

GRAND RAPIDS MI
APR 2

The Third Annual Swap and Shop will be held at the Northeast Jr. High School, 1400 Fuller Ave., N.E., Grand Rapids, Michigan, on Saturday, April 2 from 9 am to 5 pm in the cafeteria. Featured will be: CBs, monitors, ham equipment and electronic parts. For further information contact Grand Rapids React at the above address.

ST. CLAIR SHORES MI
APR 3

The South Eastern Michigan Amateur Radio Association is holding its Nineteenth Annual Hamfest on April 3, 1977 from 8 am EST to 3 pm EST. It will be held at the South Lake High School in St. Clair Shores, Michigan, 21900 Nine Mile Road and Mack Avenue. For further information contact Dorothy Spilski WB8PRJ, Secretary S.E.M.A.R.A., 11906 Riad Avenue, Detroit, Michigan 48224, 313-521-6646.

PLAIN CITY OH
AUG 14

Hamfest 77 is to be held on Sunday, August 14, 1977 at the Plain City Fairgrounds, Plain City OH. Talk-in on 146.16/76 or 146.52. Advance tickets $1.50 – gate $2.00. For additional information or reservations, write UCARC, 13613 U.S. 36, Marysville OH 43040, or call Gene Kirby W8BJN 513-642-9861.

Keeping the Wind Down

-- timer for your mobile rig

"Timing a repeater out," as the jargon goes, may not seem to be a significant event for the user, but it can generate a fury of activity on the part of the control station. With the addition of the timeout timer/alarm shown here, one can help minimize repeater timeouts.

The timeout timer/alarm does essentially one thing — keeps track of the length of time that your transmitter is on, and if it has been on longer than its timing period, deactivates it and sounds an audible alarm in the rig's own speaker. Resetting the circuit is accomplished by releasing the PTT button. If transmissions are made of durations shorter than the timing period, the normal operation of the transceiver is not affected.

The circuit operates in the following manner: Under normal conditions, point D on the schematic (collector of Q2) follows point A (base of Q1); that is, grounding point A provides a transmitter PTT ground output at point D. Generation of the warning tone and elimination of the PTT signal only occurs when point C is low and point B is high. This condition only exists if the PTT button is held in after the timer A1 has disabled the transmitter. The warning tone generated by timer A2 produces a tone in the transceiver's speaker at this time. Once again, resetting the circuit by removal of the PTT ground at point A instantly readies the rig for normal operation — until you talk too long again!

Construction is relatively simple, and should probably begin with the selection of R3 and C3, the main timing components. These values can be selected from the table or by calculation (Fig. 1). A potentiometer could be substituted for R3, but in my prototype I was interested in conserving space. My prototype was constructed on a 1" by 1.5" board and was installed in an Icom IC-230.

Hookup of the circuit requires that you break the normal PTT line, reconnecting it to points A and D, attaching the free end of R7 to the positive speaker terminal, and applying +12 volts and ground.

This circuit has already proven itself useful on more than one occasion, and I hope others will find it handy in helping to prevent unnecessary repeater timeouts. I would also like to thank Bruce Bechtol K8VAK for his assistance in the circuit's design. ■

SSB: The Third Method

- - bet you can't even name the first two

I first ran across this particular method of SSB generation some years ago when involved in a communications course. At the time I was deeply involved with getting a phasing type SSB generator on the air and only gave this method a casual glance. Never having heard of this method in the amateur journals, or of a commercial unit using this type, I was inclined to write it off as an impractical method, as I am sure many others have done before and since. This assumption couldn't be further from the truth, as the Third Method is in direct competition with the filter method. It requires neither sideband filter, nor wideband audio phase shift network (as in the phasing method), does not require critical adjustment, and any misadjustment results in interference to the user only.

As you can see, this method has much to offer the radio amateur and indeed the commercial user. The original paper on this subject was by D. K. Weaver, Jr., titled, "A Third Method of Generation and Detection of Single Sideband Signals," *Proceedings of the IRE*, December, 1956. At present this method is used in commercial equipment manufactured by Redifon Telecommunications, England, and has been since a unit was introduced in 1960.

Enough of the selling job on the Third Method – let's get into the circuit description. If you will refer to the block diagram of Fig. 1, you will note that we have four balanced modulators. These can be of any configuration. Balanced modulators A1 and B1 are operating at audio frequencies, so layout is not too critical. The circuit also requires phase shift networks. Since these are operating at only one frequency, obtaining an exact phase shift is no problem and even RC networks can be used. This application also lends itself well to digital schemes, one of which is shown in Fig. 3. The low pass filter (the one from the original paper is shown in Fig. 4) is also operating at audio frequencies and can be constructed using LC networks. It is also possible to use active audio filters.

The input audio consists of 300 to 3,000 Hz, the normal bandwidth of speech communications. When these frequencies are mixed (in balanced modulator A1) with the 1800 Hz oscillator, the modulation products that appear in the output are as shown in Fig. 2(b). In particular, note that the lower sideband is "folded" over. This results from the choice of carrier frequency. The carrier frequency is actually in the middle of the audio spectrum to be transmitted. As an example, consider an input audio signal of 500 Hz. When it is mixed with the carrier frequency of 1800 Hz, the modulation products (sum and difference components) are 1300 Hz and 2300 Hz. Next consider an input audio frequency higher than the carrier frequency, for example, 3100 Hz. When it is mixed with an 1800 Hz signal, the modulation products are 1300 Hz and 4900 Hz. Thus at the output of balanced modulator A1 we have a lower sideband which has the audio frequencies higher than 1800 Hz folded back on top of the lower audio frequencies – and all this is contained in a bandwidth of 1500 Hz. An upper sideband also extends from 2100 Hz to 5100 Hz. The upper sideband is then filtered out by the low pass filter, leaving only the lower sideband as shown in Fig. 2(c).

This "folded" lower sideband is then applied to balanced modulator A2, where it is mixed with the rf carrier.

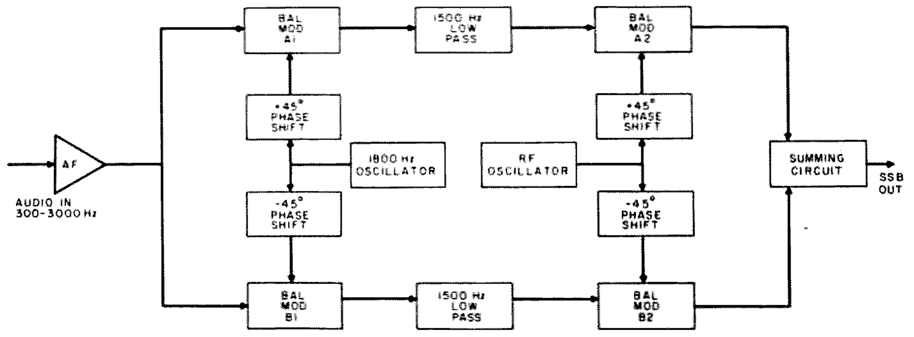

Fig. 1.

The rf carrier may be the operating frequency, or a lower frequency which is then heterodyned to the operating frequency. The output of this balanced modulator is shown in Fig. 2(d). It consists of the 0-1500 Hz "folded" sideband from modulator A1 as two double sidebands of the rf carrier, which is balanced out in A2. A careful analysis of this diagram will reveal that we are once again back to our original bandwidth of 3,000 Hz. Also, because there are both high and low original audio frequencies represented in both the resultant sidebands of balanced modulator A2, we will have both inverted and direct speech contained in the 3,000 Hz bandwidth of Fig. 2(d).

It has been shown by the phasing method of SSB generation that by using two modulator chains of the proper phases we can generate two sets of sidebands, which when added together result in cancellation of the unwanted sideband and reinforcement of the wanted sideband. Much the same technique can be used here, with the Third Method. By using two modulator chains, as shown in Fig. 1, and the proper phase shift networks (quadrature), which as stated before are for only one frequency and can be made to exhibit the exact phase shift needed with little trouble, and then adding the output of these two chains, we can reinforce the wanted sideband and cancel the unwanted sideband. The result is illustrated in Fig. 2(f). For additional clarity, the outputs of modulator chains A and B are shown in Fig. 2(e). Note that both sidebands occupy the same frequency spectrum, as well as the 180 degree phase difference between the lower sidebands.

It can be seen in Fig. 2(f) that the carrier frequency of the SSB signal, in this case for upper sideband, appears 1800 Hz below the rf oscillator frequency of the generator. This means that the carrier frequency of the sideband signal is actually not generated (due to the use of the folded sidebands). Therefore, any misadjustment of the final balanced modulators will result in the rf carrier appearing in the middle of the sideband spectrum and causing an 1800 Hz tone to be heard on the receiving end. The important fact is that no out-of-channel interference will occur. Only the user will suffer from misadjustment. Another important fact is that if there is incomplete sideband cancellation, again no out-of-channel interference will occur. The unwanted sideband will appear in the same spectrum as the wanted sideband, causing interference to the user only.

This method of single sideband generation has some very positive advantages over both the filter method and the phasing method of single sideband. I have included some sample circuitry of various parts of the Third Method SSB generator. If you are considering building an SSB generator, I hope that you will give serious consideration to the Third Method. Though it is rather complex, the construction and alignment is simplified, due to the fact that most of the circuit is at audio frequencies. The advantages are many. If anyone is interested in a more detailed and mathematical description of the circuit operation, any of the references listed will be of help. Good luck with

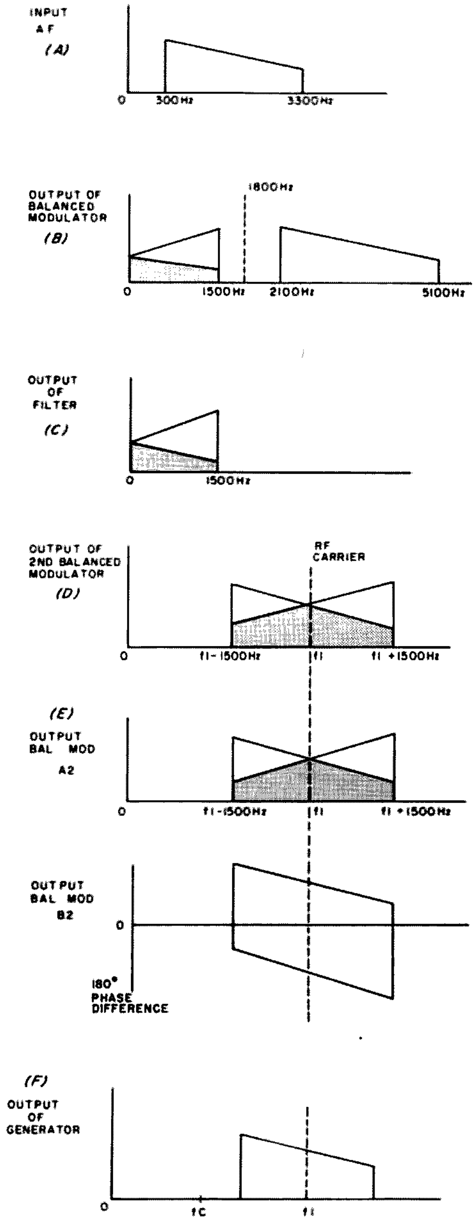

Fig. 2. (a) Represents average speech power distribution. (f) $F_C = F_1 - 1800$ Hz (upper sideband output).

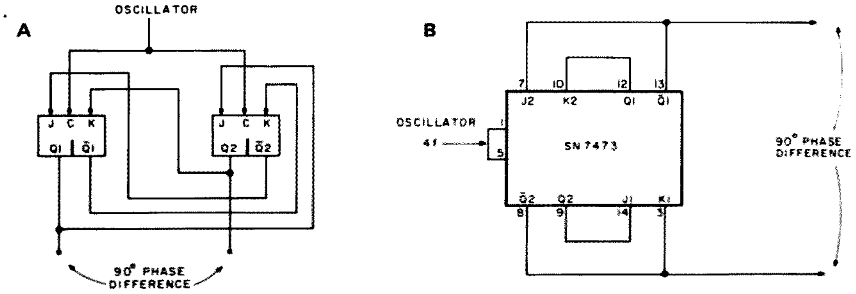

Fig. 3. (a) Using two JK flip-flops to obtain a 90° phase shift for use in Third Method generators; oscillator frequency must be four times the desired output frequency, i.e., for 1800 Hz output, oscillator frequency is 4 x 1800 = 7200 Hz. (b) 90° phase difference network using dual JK master-slave flip-flop 7473.

building a Third Method generator, and I hope to hear many of you on the air. ■

The TTL One Shot

- - another digital building block

Bill Voight WB8YJE
8065 Hillandale Dr.
San Diego CA 92120

Many amateurs are afraid to build projects using integrated circuits, either because they do not know what is going on inside the chip, or because they think that they need a room full of test equipment to get the project working. What follows is a description of four types of TTL (Transistor-Transistor Logic) monostable multivibrators, or one shots, along with some simple circuits that are useful and easy to get working. No special components or printed circuit boards are needed, and most of the necessary supplies may be found in hobby-type electronics stores.

The one shot is a nifty device that can find many uses around the shack. Basically, the one shot will put out one pulse of a specific length, regardless of the shape or duration of the input signal. A retriggerable one shot is one that may have its output pulse extended by supplying one or more additional signals at the input before the end of the output pulse. The output pulse will end after the normal time interval after the last input. Example: If you have a non-retriggerable one shot that has been set for an output pulse width of one second, and you apply a very short input pulse to it every three-quarters of a second, you will get a string of 1 second pulses out with a space of ½ second between each pulse. If the same input were applied to a retriggerable one shot, you would get a continuous output until 1 second after the last input pulse.

Fig. 1 shows the pin assignments and function tables for the 74121, 74122, 74123, and 74221 monostable multivibrators. The inputs labeled A on the pin assignments diagram are the negative-transition triggered inputs. A signal at these pins will trigger an output pulse when it transitions from a high level to a low level if all other inputs are high. The inputs labeled B are the positive-transition triggered inputs, and will cause an output pulse to begin when the input at these pins goes from a low level to a high level as long as any other B inputs are high and at least one A input is low. For these TTL devices, a high should be between 2 and 4.5 volts and a low should be from 0.8 to 0 volts.

The outputs from these one shots are complementary: The Q output is normally low and goes high when the input is triggered, the $\overline{Q}$ (pronounced Q-not) output is normally high and goes low. The length of the output pulse is determined by an external resistor and capacitor connected to the pins marked Rext/Cext and Cext for each one shot. The length of the output pulse may be determined from some involved equations provided on the manufacturer's data sheet for each type of one shot. For amateur purposes, the pulse length may be approximated by

$$T = K \cdot Rext \cdot Cext$$

where:

T is the pulse length in milliseconds
Rext is in k Ohms
Cext is in microfarads
K = .7 for the 74121 and 74221, .32 for the 74122, .28 for the 74123

The 74121 and 74122 have internal fixed resistors, marked Rint on the diagram, which may be used as all or part of Rext. The value of Rint is 2k for the 74121 and 10k for the 74122.

Perhaps the best way to become familiar with these one shots is to build some small practical circuits. Fig. 2 is a simple T/R switch (or VOX, COR, etc.). This circuit uses a single retriggerable one shot and one NAND gate.

The output of a NAND gate is high unless both inputs are high. In this circuit, the input and the $\overline{Q}$ output of the one shot are both normally high and hold the output of the NAND gate low, so the transistor will be off and the relay will be de-energized. When the input goes low (during key down, speech, or whatever), pin 1 of the 7400 goes low and pin 3 goes high, causing the transistor to conduct and closing the relay. When the input returns high, the positive transition at the B input of the one shot causes the $\overline{Q}$ output to go low for the period determined by the DELAY potentiometer. This keeps pin 2 of the 7400 low and pin 3 high for the time between dots or dashes and will time out and cause the relay to de-energize if another input signal does not occur before the end of the delay period. Either the 74122 or ½ of a 74123 retriggerable one shot may be used in this circuit, but the input must be kept compatible with the TTL devices (between 0 V and 4.5 V). Unused B inputs should be tied to Vcc through a 1k resistor. Unused A inputs should be tied to the A input that is used. This is true for all of the circuits described here.

A square wave generator or pulse generator is shown in Fig. 3. The 25k dual pot will give an almost symmetrical output waveform. Two single pots may be used if the up time and down time of the output are to be adjusted independently. When the switch is in the OFF position, the A input of A1 is held high and prevents any output. When the switch is moved to the ON position, the negative transition at the A input causes the Q output of A1 to go high for the time T_1 determined by the setting of the FREQ pot. Then, when this pulse falls, it triggers the A

Technical data and pin assignments diagrams for this article were taken from the *TTL Data Book for Design Engineers*, First Edition, published by Texas Instruments, Dallas TX.

Fig. 2. A simple T/R switch using a retriggerable one shot and one NAND gate. Switch may be removed and other TTL-compatible input applied at point X for practical applications.

input of the second one shot, A2, and the output is taken from the Q output of A2. The Q̄ output of A2 rises at the end of time period T_2, and triggers the B input of A1 to start another sequence. This will continue until the switch is turned OFF.

With the short pulses encountered in TTL logic, an oscilloscope is almost a necessity, but a good oscilloscope may cost a small fortune. Fig. 4 shows a gadget that is useful for "viewing" the workings of TTL logic if you do not have an oscilloscope available, and can be a handy accessory even if you do. The one shot is used here to light LEDs when transitions of the input are detected. Even very short pulses are visible on the LEDs, since the one shot "stretches" the pulse length. One half of a 74123 is used to detect positive-going transitions and light D1. The other half detects negative-going transitions and lights D3. D2 will light any time the input is at a high level. If the input is a constant high level, D1 will blink on and then go off because of the positive transition when you first apply the input, and D2 will come on for the duration of the high level. When the input is removed, D2 will go out, and D3 will blink on and then go off because of the negative transition. If the input is a series of pulses, the LEDs will either blink in sequence or stay on all the time, depending on the pulse width and

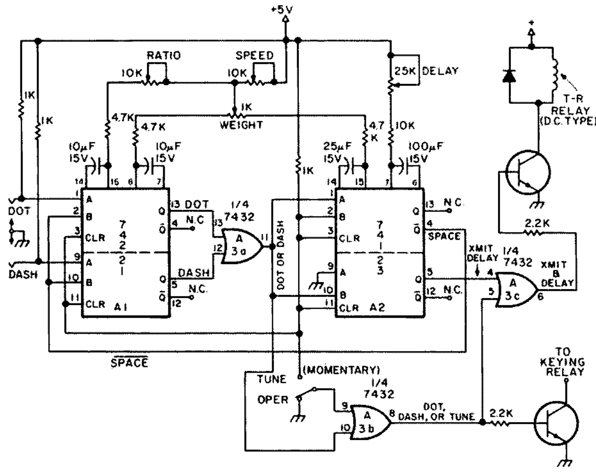

Fig. 5. An electronic keyer that provides for control of the T/R relay.

repetition rate. The Rext resistors may be made variable for more flexibility.

With a little experience in using this device, you can get a pretty good idea of how the circuit under test is performing. Of course, a scope would give an even better idea, but you get what you pay for.

The keyer of Fig. 5 looks fairly complex at first glance, but it is really only a combination of the circuits of Figs. 2 and 3. It uses only three integrated circuits and provides control of the T/R relay for break-in operation. The entire circuit was built on two experimenter boards that were purchased at the local hobby electronics store. The 74221 forms the dots or dashes. This part of the keyer works like A1 of Fig. 3, except that the paddle selects which side of the IC will put out the pulse. Pin 1 of the 74123 acts like the A input of A2 in Fig. 3, and this half of the 74123 makes the spaces between the dots or dashes. The remaining half of the 74123 and A3b and A3c are similar to the T/R switch of Fig. 2. OR gates are used here instead of a NAND gate, and the Q output of the one shot is used instead of the $\bar{Q}$ output, but the circuit is basically the same.

The information presented here should give you an idea of what one shots do and how to hook them up. If you haven't tried using ICs yet, why not get started by trying a few projects using one shots? ■

DVMs Get Simpler and Simpler

- - wait'll you see the MC-1405!

With all of the interest in digital electronics, and with prices of the related parts dropping, it seems natural to me that much of the equipment in our labs and shacks could be "digitized." The result would be that equipment would be much easier to read (no analog meters to interpret) and perhaps the readings would be more accurate. This is part of the rationale I used to justify starting this project – to design a digital voltmeter so cheap and easy to build it could be included in my power supplies, communications gear, etc. It would also be nice to have a digital multimeter, too. So with that I got started.

You may be aware of the fact that many semiconductor houses offer *digital voltmeter* chip sets. These consist of an analog to digital converter chip and a digital counter array chip. All you have to add, at the most, are a power supply, a system clock, a reference source and a display system. That can easily mean six chips and up! This means high cost and lots of construction. I know because I built several voltmeters this way, and that includes a so-called "One Chip Voltmeter!" But there is a better way.

Motorola has introduced a chip set that requires only a power supply and a display system. It's easy to work with and easy to calibrate. And the best part is that it's available and cheap (under $18 for the set), too! Accuracy is rated at 0.05% and that is probably worst case! Your voltmeter accuracy will depend upon the accuracy of the standard you use. I'll show you how to build a good one. This is the system our "Cheap and Dirty DVM" is based on!

I feel I should mention some of the disadvantages of our DVM, to be fair. The first one is that it won't measure negative voltages. You have to reverse the input leads for that, like on an analog VOM. The second disadvantage is that the chip set has an input impedance of 4k Ohms, but this is changed to 10 megohms input with a $2.00 op amp in our unit. None of these problems are serious – the first requires a quad op amp and some parts. The second has already been taken care of. I'll discuss the solution to the polarity problem in a future article *and* show you how to measure ac volts and Ohms at the same time. If you want to read further about the Motorola chip set, call or write them for the data sheets and ap notes listed at the end of this article.

Construction isn't too difficult, but there are several areas to watch. Probably the biggest problem you will have is finding a box to house the finished unit. If you want a general purpose meter to be used around the shack, a minibox will work fine. However, if you are like me and want to build a digital panel meter to be installed permanently in a piece of equipment, you are in a sticky situation, as digital panel meter cases are very hard to get! I finally found a few in surplus, but I can't get enough to share the wealth. Let me suggest you use a small minibox if you're stuck. Cut a rectangular hole in the

Photos by Roger Wilcox

front of the box and put a red filter behind it. Then cut and bend aluminum stock into two L brackets, large enough to fit on the ends of the box. You could then cut a hole large enough to accommodate the box front in your panel and use the L brackets to secure it. A possibly better way would be to make up an aluminum plate larger than the front of the box and use it to secure the box to the panel. You would have to duplicate the display cutout in the plate, of course, but the result could look pretty neat!

If you have never built a digital voltmeter before, you are in for some interesting construction! If you have, the construction hints I am about to give will sound familiar. The layout isn't too critical, and the parts may be placed nearly anywhere. However, I would like to suggest that the heat generating power supply be located as far away as possible from the MC-1405 chip. In fact, try to get it in a separate module. The layout for one of my digital panel meters, despite the close proximity of the power supply components, hasn't caused any problems, but you never know. Why the caution? Heat may cause drift of calibration if it is great enough. By the way, this circuit draws around 100 mA from the +5 volt line. Also, when you wire up the LM-308 and the MC-1405 circuitry, the grounds are critical. Improper grounding causes calibration errors, drift, and other problems. You'll notice how all grounds come together at one point on the schematic; this is the way to wire your unit! Remember that this voltmeter can be a laboratory quality instrument if you follow my simple precautions.

I built up six different units and I built them pretty much alike. First, I assembled the display board. Three HP 5082-7740 LED readouts were used for the multiplexed part, and an HP 5082-7730 readout was used for the 1 on the display. Note that the 7740 readouts are *common cathode* and the 7730 is *common anode*. You could use all 7740s if you wish. Or even Data Lit 704s; you name it in common cathode! A separate LED was used for the decimal point; this makes for easier reading at a distance. The three 7740s were wired up for multiplex operation; this means that all A segments were wired together, all Bs and so on. Homemade L brackets were used to attach the completed display to the rest of the electronics board.

The next part of this project is to get the electronics built and running. Fig. 1 shows the schematic of the basic meter. This is the circuitry that is recommended by Motorola for their chip set, so you'll find it well described in their ap notes and bulletins. The illustrations show one of my first meters – a panel meter in a power supply. Both the schematic and the illustrations should help you get your unit built and on the air, pronto!

I built my first units on scraps of copperclad perfboard, known as "ground plane" board. This method of construction works fairly well, because the grounds are very easy to make, but extra time is required to drill out the copper from holes where parts are going to be mounted. Regular perfboard works fine, though, and you are welcome to use this method. It's also cheaper and you don't have to worry about shorting IC pins to a copper ground plane. I started building my units by installing the IC sockets and wiring up the grounds. On the non-ground plane boards, I brought the grounds from all ICs to one point – pin 8 on IC2. The #24 bare wire I used for all connections worked just fine. Then with the hard part over, I wired up the rest of the unit. Note that the pin numbers on IC1 are for the TO-5 can. If you use the DIP version of the LM-308, you have to look up the new numbers. The driver transistors, Q1 through Q4, are not critical. Almost any silicon NPN unit with a beta of 100 or better will work for Q1. And any silicon PNP units with betas of 100 and up will work for Q2 through Q4. I suggest 2N3904 and 2N3906 because they have given me the most consistently good results. If you can't easily buy the ICs, try Circuit Specialists, PO Box 3047, Scottsdale AZ 85257. They can help. The MC1405L is $8.95, and the MC14435VP is only $7.95. The LM308 is available from Radio Shack. Yes, the parts are available for this project!

As you finish up the electronics board, I would like to make a comment about the pots you use for R1 and R2. Don't try to squeeze by through subbing single turn pots. They will be very hard to adjust and you probably

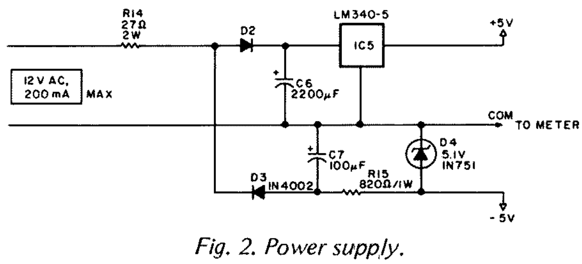

Fig. 2. Power supply.

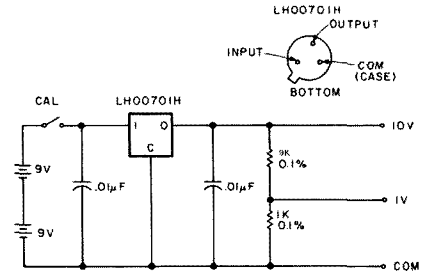

Fig. 3. Calibrator.

won't be able to calibrate. Always use 10 turn wire wound units, or better yet, 20 turn units if you have the space. I found mine for 50 cents each at Poly Paks. The exact resistance values aren't especially critical, so you can sub pots fairly easily. Another thing you can do with the pots is to "remote" them by mounting them off the electronics board and attaching them with wires. You'll notice that I went this route with the unit in the photos. Be safe and bring out separate ground wires for each pot. As before with the other wiring, terminate them at pin 8 of IC2. I finished up by attaching the display board to the electronics board with homemade L brackets on my units. Use resistors R7 through R13 to attach the display segments to IC4 and save yourself some wire.

You may need a power supply. You'll need plus 5 volts at about 100 mA, and minus 5 volts at about 10 mA. You might be able to borrow these voltages from other equipment if they are regulated. If not, build the optional power supply shown in Fig. 2, and power your voltmeter from a 12 volt filament transformer. I did this with the unit shown; one of the power supply's internal transformers had an extra 12 volt, 250 mA winding, so I used it. You could also use one of those line plug transformers used for calculators, if you open the case and remove the diodes that are usually there.

You might want to add a range switch to the input of your new meter, or perhaps just change ranges. As built, it measures 0 to 2 volts. Fig. 4 shows some ideas for attenuators, both simple and deluxe. I built the simple one into the power supply voltmeter. I needed a 0 to 20 volt meter, so I made a x10 divider. R_B was 10k, 1%, and R_A was 100k, 1%. Ideally, these resistors should add up to 10 meg, the standard digital voltmeter input resistance, but in a power supply, these resistances aren't critical (no loading problem!). Also, I had these values! You can use whatever precision resistors you have for x10, x100, or even x1000 dividers. If you don't need a divider at all, connect a 10 megohm resistor across the voltmeter input to cut zero drift when the test leads are open. The deluxe divider shown is what you would use in a digital multimeter. It features 10 megohms input resistance and overload protection. For best results use 0.1% resistors throughout. You will also want some kind of decimal point switching on the display; that will mean another deck on the range switch and two more LED/dropping resistor combinations.

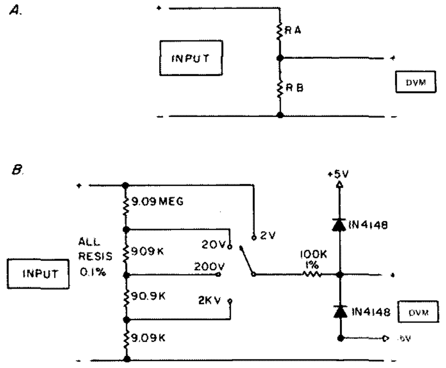

Fig. 4. Input attenuators, simple (a) and deluxe (b).

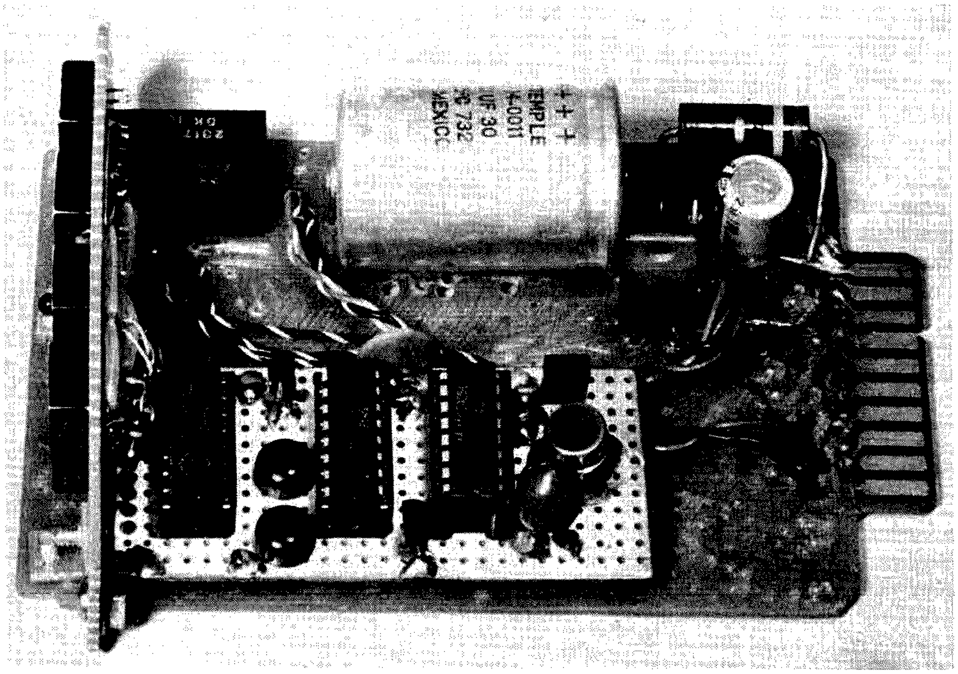
Calibration is quick and easy once you are set up. Beg, borrow or ? a dc voltmeter calibrator that is at least 0.01% accurate. Or, lacking that, you can build the calibrator shown in Fig. 3. It is designed around the National LH0070IH 0.01% 10 volt reference, which sells for about $5.00. Circuit Specialists might be able to get one for you. Power is supplied by two 9 volt batteries. Lacking this calibrator, you can either calibrate your voltmeter against another DVM, or (shudder) with a 1.34 volt mercury battery. The battery is a last resort, because you might be able to get only about 1% accuracy or so, depending upon the condition of the battery (it should be fresh and unused).

With that out of the way, connect up the voltmeter and apply power. Let it settle down for about 20 minutes or so and then short the input leads together. Adjust the zero pot, R2, for a 000 reading. You'll see the meter read something like 087 – 093 – 097 – 098 – 099 – 000 – 001 – 002 if all's well.

Once the zero is adjusted, apply either +2.000 volts



from the commercial calibrator (preferred) or +1.000 volts from our calibrator. This is assuming you have the basic 0 to 2 volt unit; for other units increase the input voltage by x10, x100 or whatever. Then tweak R1, the calibration pot, for a 1.999 to .000 reading (or 1.000 with a 1 volt calibrator). Go back and short the input leads to check the zero; if it is necessary to adjust zero, recheck the calibration, too. These adjustments interact somewhat.

I hope you like your new "Cheap and Dirty Digital Voltmeter." It really adds a touch of class to have equipment in the shack with digital readouts. The price is right, too; you probably spent about ¼ as much for your meter as you would have for a commercial unit! ■

Parts List

C1 – 4.7 uF, 10 volt electrolytic cap
C101 – 100 pF disc cap
C2 – 47 uF, 10 volt tantalum or electrolytic cap
C3 – 0.01 uF disc cap
C4 – 220 uF, 10 volt electrolytic cap
C5 – 0.0033 uF disc cap
C6 – 2200 uF, 25 volt electrolytic cap
C7 – 100 uF, 25 volt electrolytic cap
D1 – 1N4148 diode
D2, D3 – 1N4002 diode
D4 – 1N751 zener diode, 5.1 volts
IC1 – LM308 Radio Shack
IC2 – MC1405L Circuit Specialists
IC3 – MC14435VP Circuit Specialists
IC4 – MC14511P Circuit Specialists
IC5 – LM340-5 Circuit Specialists
Q1 – 2N3904 transistor
Q2-Q4 – 2N3904 transistor
R1 – 5k trimmer
R2 – 20k trimmer
R3 – 10k resistor
R4 – 10k resistor
R5 – 470 Ohm resistor
R6 – 2.2k resistor
R7-R13 – 150 Ohm resistor
R14 – 27 Ohm, 2 Watt resistor
R15 – 820 Ohm, ½ Watt resistor
All resistors ¼ Watt unless noted
DIS 1 – HP 5082-7730 Common Anode Display
DIS 2 to DIS 4 – HP 5082-7740 Common Cathode Displays
DIS 5 Man 5024 LED
Misc: Case for meter, perfboard, assorted wire, etc.

Instant PC Boards

-- using new Color-Key technique

More people would make printed circuit boards by the photographic method if they weren't discouraged by the chemical processes and darkroom requirements that are necessary to produce a film negative from their positive artwork master. Although I have a complete darkroom setup for developing and printing black and white and color film, I have never actually

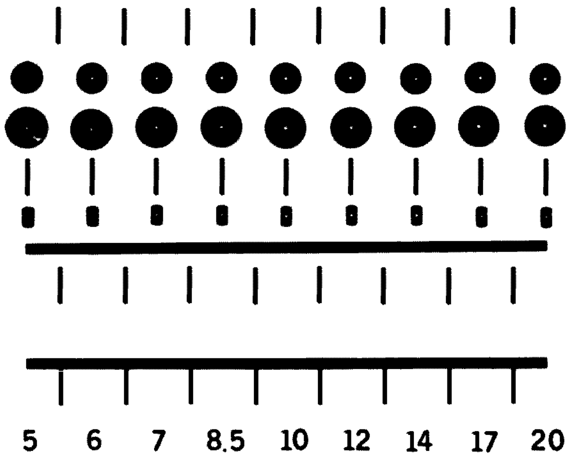

Fig. 1. Color-Key exposure test artwork.

used a photographic film for making printed circuit negatives because there is a material called Color-Key that is far more convenient to use and does not require the array of chemicals, trays and accessories demanded by photographic film.

While a darkened area is necessary during the time the positive artwork and the Color-Key negative material are placed together in some type of holder before the exposure, it doesn't have to be a darkroom. It can be any room or closet lighted by subdued artificial light. A sunlit room cannot be used as the Color-Key material is sensitive to ultraviolet radiation.

After exposure, the Color-Key material needs only to be developed to make an excellent printed circuit negative. The developing step is very simple and doesn't even require a tray, just a flat surface to lay the material on while applying the liquid developer to the sensitized side. No trays, shortstop, fixer or temperature control; you even work in normal room light. After development, just hold the negative under the cold water faucet for a few seconds to wash away the residue and hang the negative up to dry.

Color-Key contact imaging material, as the manufacturer identifies it, is a product of 3-M. It is supplied in several colors and as a negative material or as a direct positive material. It is sold in boxes of 25 sheets and the smallest size is 8½ by 11 inches. I have been purchasing it from a large photographic supply store. It's also available at some art and drafting supply stores as it is used in the preparation of ads by some advertising agencies.

I have been using the type identified as black opaque negative acting material. When exposed and developed, it gives a solid black and clear transparent image, just what is needed for printing a sensitized board.

The developer for Color-Key material is sold in ready-to-use liquid form. It is identified as negative acting developer for Color-Key material. A quart of developer is sufficient to develop a box of 25 sheets of the 8½ by 11 inch size.

As the name suggests, the material is intended for contact printing; that is, the positive artwork is placed in contact with the material during the exposure. Ultraviolet radiation must be used for exposure, in the same manner that sensitized printed circuit boards are exposed. Direct sunlight is a source of ultraviolet radiation, but a more practical source for making negatives (and PC boards) is an ultraviolet lamp. While the same exposure setup can be used for printing negatives and boards, the exposure time is

not necessarily the same for each.

I have been using a small 15 Watt ultraviolet fluorescent tube which I bought complete with fixture for less than $20 for exposing negatives and boards. The lamps and fixtures are sold at large self-service hardware and variety stores.

I use an 8 by 10 inch photographic contact proof printer to hold the positive artwork in contact with the Color-Key material during the exposure. Lacking a contact printer, a small piece of window glass from the hardware store could be used to weight down the positive and negative material. The Color-Key material has a natural curl so it must be flattened during the exposure.

The sheets of Color-Key material can be cut to match the size of the artwork before making the exposure. You can work in a fair amount of artificial light without exposing the Color-Key. I have a bare 15 Watt bulb plugged into an outlet about 3 feet away while cutting the material and placing the negative material and the artwork positive in the contact printer. Once the contact printer is loaded, I turn on a 60 Watt overhead fixture which remains on during the exposure and development steps.

Like photographic film, the Color-Key material has a shiny and a dull side. The dull side contains the sensitive material while the shiny side is the transparent base. Exposure is made through the shiny side, which requires the dull side to be placed down in the contact printer and the artwork positive placed right side up over the Color-Key material in contact with the shiny side.

When the exposure is completed, the Color-Key material is ready for its single processing step, development. Unlike film which is soaked in a tray of developer for a specific time, Color-Key material is developed by laying it on a flat surface, dull side up, and rubbing a small amount of the liquid developer over it until the image is formed. The black material that is removed to form the image comes off very quickly in the form of a sludge.

I use a piece of window glass about 14 by 20 inches for the flat surface. The exposed material is placed dull side up on the glass and a small amount of developer is poured over the negative. The natural curl of the material aids in keeping the developer from running off the negative. The instructions suggest the use of special pad and pad holder to rub the developer over the negative, but a piece of facial tissue works very well and costs much less. The developer is rubbed over the dull side with the tissue until the image is complete. This takes only a few seconds and since the overhead light is on during development, the image can be seen forming as the black is removed. When the image is complete, the negative is washed under cold running water for a few seconds to remove the residue and then hung up to dry.

Rubbing too hard or too long will remove some black material from areas where it should remain. You can avoid rubbing to excess with a little care, since with the light on you can see the image appearing. If an area doesn't seem to respond to development, add a little developer liquid instead of rubbing harder.

It is possible to develop the negative so quickly that the first rub with the tissue will reveal the image. I run hot water from the faucet over the glass developer plate for several minutes while the exposure is finishing, stopping the hot water a minute before the exposure is completed. The glass plate is placed on several folded newspapers to retain the heat. The warm glass plate under the negative activates the developer so much that development takes place before you can pick up the tissue and begin to rub. Developing the Color-Key on a warm plate seems to produce better negatives as the black material left on to form the image appears to be bonded to the base much more tightly than when the development is accomplished at room temperature. The developer itself should not be heated as it may exhaust itself, although it may be warmed slightly if it has been stored in a cold location.

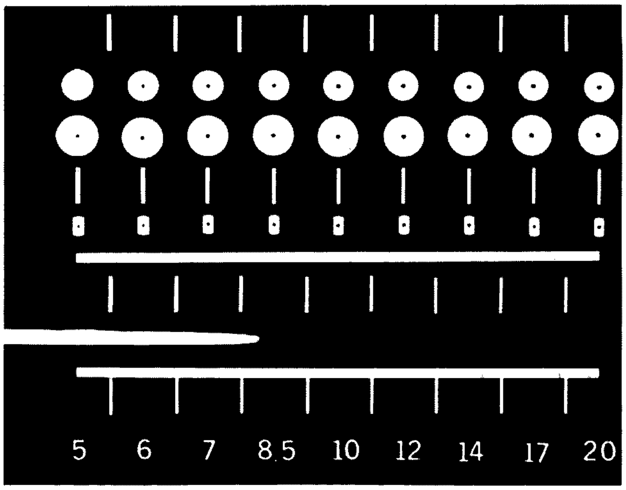

Fig. 2. Color-Key exposure test negative.

Exposure time for each ultraviolet lamp and film holder has to be determined by test. Exposure depends on the amount of ultraviolet radiated by the lamp, the distance the radiation has to travel to reach the sensitized material and the attenuation of the glass in the contact printer or film holder. My ultraviolet lamp is positioned 8 inches above the glass in the contact printer and my exposure time is 14 minutes. Lowering the lamp would reduce the exposure time, but could cause the exposure to be insufficient at the edges of large pieces of the negative material as the rays have to travel a greater distance from the lamp to reach the edge than to the center of the contact printer. If I felt a need to shorten the exposure time, I would add a second lamp as the most practical way to do it.

Finding an exposure time that will work satisfactorily is fairly simple. It can be done by using a test positive that has been made to aid in determining the correct exposure time. Since our prime use for the Color-Key material is to make printed circuit board negatives, I made a test positive using printed circuit decals for solder pads, lines and IC pads. Fig. 1 is the test positive 1 used to determine exposure time for the Color-Key material in my exposure setup.

The test positive is divided into nine sections as identified by the numbers at the bottom. The number 20 at the far right means that section will be exposed for 20 minutes. The four items in the section above the number 20, an IC pad, a short thin line and two solder pads, are the items to be exposed and examined on the negative to determine the exposure time for Color-Key negatives.

Each numbered section contains the same four items, and the section number is the time in minutes the section should be exposed to ultraviolet radiation. After exposing and developing the negative, the section which shows the best reproduction of the items will be selected as having the correct exposure time. The various lines separating the sections are

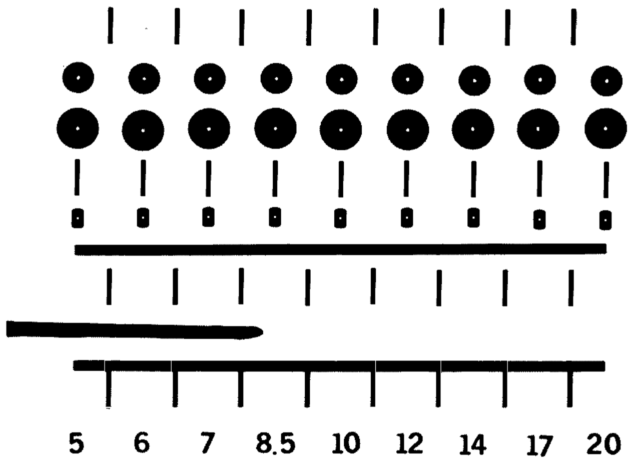

Fig. 3. Color-Key positive made from test negative.

guidelines for exposing the negative and cannot be used for evaluation of the negative.

Exposure is made by placing a piece of Color-Key material and the test positive in the contact printer or film holder that will always be used for making Color-Key negatives and placing a piece of dark paper or cardboard on the contact printer so it covers the sections that have received their allocated exposure.

To begin, place the cardboard over the section numbers at the bottom, leaving all the sections uncovered, and place the contact printer under the ultraviolet source. After a 5 minute exposure, remove the cardboard from over the section numbers and use it to cover the section marked 5. The numbers at the bottom and sections 6 through 20 should be exposed for 1 minute. Note that the bottom numbers are not covered again after the 5 minute exposure. They are to receive all subsequent exposures. After the 1 minute exposure, slide the cardboard to the right to cover section 6, leaving section 5 covered. After a 1 minute exposure of sections 7 through 20, move the cardboard to cover section 7. Expose sections 8.5 through 20 to the ultraviolet radiation for 1.5 minutes. The slide the cardboard to the right to cover section 8.5 and expose sections 10 through 20 for 1.5 minutes. After 1.5 minutes, move the cardboard to cover section 10, keeping the previously exposed sections covered and expose sections 12 through 20 for 2 minutes. Then cover section 12 and expose sections 14 through 20 for 2 minutes. Slide the cardboard to the right and cover section 14. Expose sections 17 and 20 for three minutes. Slide the cardboard over section 17 and expose section 20 for three minutes.

When the test exposure is completed, each section of the negative will have received a total exposure in minutes equal to the number of the section and the numbers at the bottom will have been exposed for 15 minutes. While performing the exposures it is not necessary to turn the ultraviolet lamp on and off. The cardboard can be repositioned in less than a second and the resulting exposures will probably be more accurate than if you try to control the radiation by switching it on and off. Be sure your cardboard is large enough to cover sections 5 through 17, that it will not be obstructed by nearby objects and that you use a small weight to hold it in position if it extends past the edge of your film holder or contact printer.

After developing the negative, each section should be carefully examined to determine the best exposure time. My test negative, Fig. 2, shows that it was badly underexposed at 5 minutes. The dot is missing in the small solder pad, the other pad dots are too small and some of the black near the large pad came off because of the underexposure. Fig. 3 is a positive made from the test negative and perhaps may be more easily read. Sections 6 and 7 are better but are still underexposed as the holes in the pads are undersized. This shows very clearly in the IC pads. Section 8.5 is much better, while sections 10 through 17 look very good. Section 20 is overexposed, as can be seen by the slight enlargement of the pad holes. This is more easily seen in Fig. 2, the negative, as overexposure is easier to determine by noting an increase in the size of dots.

The clear strip that begins at the left edge of the negative and runs through section 10 was caused by the edge of the cardboard used for masking off the sections and should not be considered in evaluating the negative.

Fourteen minutes was chosen as the correct exposure time, as that results in a negative where the subjects are the identical size as on the positive. While this is difficult to see from examining the figures with this article, you will find when you make your own test negative the easiest way to evaluate the results is to place the test positive over the developed negative and align the items in each section. You will discover that the underexposed negative subjects are larger than the positive ones, as the positive items will not completely cover the negative subjects in the sections that were underexposed. In the overexposed sections, the reverse is true. The subjects on the positive are larger than their negative images in the overexposed sections. The closest size match between positive and negative images is in the section that has received the most nearly correct exposure to the ultraviolet radiation.

The positive in Fig. 3 was made by exposing the test negative for 14 minutes. This has always been about the correct exposure time for my untraviolet lamp and contact printer when spaced 8 inches apart. These exposures were made recently and duplicate the results of the test I made four years ago when I began using Color-Key material. Apparently the ultraviolet radiation from my lamp hasn't changed after several hundred hours of use.

If your first test negative is completely under- or overexposed, multiply the exposure time for each section by 2 if underexposed or by 0.5 if it was overexposed and print a second negative.

If your exposure time is much longer than anticipated, the problem could be the glass used in the contact printer or film holder. Some types of glass block out ultraviolet radiation fairly effectively. The glass in my contact printer is ordinary plate glass, as I had to replace the original glass which shattered from the heat of a 500 Watt bulb, my first source of ultraviolet.

While practically any source of ultraviolet radiation also emits some visible light, the amount of ultraviolet cannot be judged by the quantity of visible light. Ultraviolet radiations are not visible and can be harmful in large doses. You can be "sunburned" by large amounts or even have your eyes affected just as can happen by excessive exposure to the sun. The ultraviolet radiation from the sun causes the sunburn. The 15 Watt fluorescent lamp should cause no problems, but if one is tempted to obtain a more powerful source of ultraviolet radiation, he should also buy a pair of goggles specifically designed to block ultraviolet radiation.■

I/O EDITORIAL

GETTING STARTED

The chances are that you may be thinking about maybe getting a microcomputer. With many of them appearing to be in the $300 to $500 price bracket, it isn't something where you are going to send away a check blindly. And you're probably still asking a lot of questions about what you are going to be able to do with it if you do get it.

There are a discouraging number of alternatives, so perhaps if I lay down some guidelines it will help. I'd make specific recommendations, but that would upset some manufacturers . . . and let us not ignore them as is paying the bills for the magazine.

The heart of a computer these days is the chip of your choice: 8080, 6800, 6502, Z-80, etc. This is nestled in the central processing unit (CPU). Each chip has its clique and there are enough pros and cons for each to bring on a fistfight in the most peaceful of computer clubs. The proponents of the Z-80 have some persuasive arguments, since it is a sort of super 8080 contraption, with some of the charm of the 6800 thrown in to confuse Motorola fans. Having given you little real help with this aspect of your system (the key to the whole thing), we can pass on to less substantive matters.

In addition to the CPU, you'll be needing a good sturdy power supply and a nice cabinet. None of the manufacturers have yet caught on to the Star Trek type of computer . . . the one with the thousands of flashing lights and brilliant colors . . . and we all know way down in our subconscious that any real computer is going to look like that. Who wants a box with a switch and pilot light on the front? That's not a computer!

Now, about that power supply. You'll either start out with a heavy duty supply or you will rue the day and end up modifying it or adding more supplies later on. A little research will give you a good general idea of how much power you are going to need. Figure on a CPU, at least 16K of memory, a couple I/O boards, a PROM board, character and graphics generators, etc. Once you've added up the current needs of all that, you might as well double it, because you will hardly ever be cutting down on your system . . . there will always be some new and exciting gadget which will plug in to let you do something else . . . it might be generating full color art . . . writing music . . . some special games such as Tank . . . you don't know what. Looking up the specifications for the many boards available (over 150 are now designed for the Altair Bus) will help you get familiar with this new world.

Memory. It's expensive and you're going to want to buy as little as you can to save money . . . and as much as you can afford to make your system work better. Your presently available systems will generally support a maximum of 64K of memory. I doubt if your pocket will. Mine doesn't. You can't get along with much less than 12K since most of the BASICs take 8K of that and need some elbow room to be used. There are some Tiny BASICs which only use 4K, but I doubt if you will be satisfied with the restrictions of Tiny for long.

You'll need input/output (I/O) boards to permit you to communicate with the CPU. You get into a lot of complication with these things with serial vs parallel, baud rates, parity bits, and all that other stuff which you'll eventually learn via articles in the magazines. You can hook a lot of different things into your system . . . a Teletype, a CRT (also known as a television typewriter, TVT, or video display terminal, VDT, or just plain "tube"), a cassette recorder, a paper tape system, magnetic tape . . . etc.

You should be aware that all of the Teletype compatible I/O boards are 20 mA systems which are designed to match the ASR-33 and 35, and these machines start around $800 or so. That Teletype you have in the shack is probably a Model 15 or 19 and it needs 60 mA to operate, so you'll have to build an interface between the two. Your machine speaks Baudot code and the I/O talks only ASCII, so you need a converter for that . . . or a program in lieu of the hardware. It probably won't be long until there is a Baudot I/O board for 60 mA machines available, but I haven't seen one yet.

The VDT is probably the handiest way of communicating with your computer. The selection of these available is very limited so far . . . with the Southwest Tech CT-1024 being the most used. This comes in kit form (it is fun to build) and requires you to use a black and white television set for the display. Since TV sets are selling for under $100 brand new these days, it is a reasonable path. The HAL keyboard and character generator also use a TV set. Many of the surplus keyboards are fine, but be wary of some of the complete VDTs in surplus . . . some of them take a lot of know-how to convert and I've been unable to get much in the way of articles on them so far.

Once you have your CPU, the power supply, a beautiful cabinet, a VDT, and plenty of memory, you are ready for the big leagues. Your system will be capable of doing an amazing number of things . . . like keeping the log, keeping track of OSCAR, translating CW or RTTY, playing a hundred or so games, running many business programs, etc. Note that I said "capable." The fact is more like it will be a fantastic coffee table conversation piece until you get software. There are few other instances where a hobbyist is able to spend so much money and time and end up with something which is in perfect working order and still is totally unusable.

If you've invested in a CPU on the basis of hype and color pictures, you could join a not insubstantial group of hobbyists way up at the end of a very familiar creek. There are some people who live and breathe to program computers. It is unlikely that you are one of these . . . or even know one. This cat does not even get close to such as us, and if he did, we wouldn't be able to talk with him. All too late many hobbyists have begun to realize that all that bunk about hardware only being half of a computer may have some basis in fact. Don't say I didn't warn you.

Okay . . . programs. How do we get programs? Firstly, you make sure that the system you are going into has software available . . . and available where you can get it. You'll want to be sure they have BASIC on hand, and while Tiny BASIC is a lot of fun, this will limit you in the number of published programs you can get running. Make sure you will be getting an 8K or better BASIC. If you have that, you will be able to use programs published in books and hobby computer magazines to go the rest of the route.

Eventually there will be other languages available . . . FORTRAN is certain to come soon. In the meanwhile, you'll soon get used to BASIC and enjoy writing many of your own programs. Without a language such as BASIC, you are stuck with machine language . . . which is no language at all. With this you have to put in every single step of the program in binary. Some experienced computerists may love machine language; however, I suspect that this is a love which requires considerable cultivation . . . and not a little masochism.

A little while back I briefly mentioned cassettes. I was covering up a lot of confusion with vagueness in the process. The fact is that the microcomputer industry definitely does not have its . . . er . . . act together when it comes to cassette systems. If you want to get a heated argument going, just walk up to a group of computerists and say you think such and such a cassette system is best . . . and stand back. You can fill in the blank with Tarbell, Kansas City, Mits, Digital Group, National Multiplex, etc. They're all different and all have *something* in their favor. Your best bet, for the time being, is to go with whatever system the CPU manufacturer likes at the moment and figure that you're going to have to change before long.

There is much to be said for going with the most popular systems. Along this route you'll find more help from fellow sufferers . . . more peripherals . . . more options . . . more articles . . . and a whole lot more programs.

So what's the most popular system? No one in the industry is giving out any sales figures, but I've looked carefully into my crystal ball and I think it works out about like this . . . at least for the hobby computer market . . .

System	*My Guess*
Altair 8080	2650
Imsai 8080	1025
Other 8080 type	515
Z-80 type	525
8008 type	550
Southwest Tech 6800	600
Sphere 6800	140
Other 6800 type	600
OSI 6502	230
Kim 1 6502	450
All other hobby systems	1825

Yes, I realize that the total comes to a bit over 9,000 hobby systems, but that's what I see out there. You can bet I'll be running polls in *KB* to keep tabs on what systems are selling and what peripherals are being used with them. The above does not include the microcomputer systems which have been sold to firms for later resale . . . called original equipment manufacturer (OEM) sales.

Since we're projecting a readership of about 35,000 for the third issue of *Kilobaud*, it is obvious that the great percentage of computer hobbyists have yet to buy hardware. I doubt if they would be subscribing to *KB* if they weren't serious enough about computers to want their own, so we're looking at a considerable market among the *KB* readers for hardware. This is probably one of the best times in history for the entrepreneur to put a product on the market and build up a company . . . but I digress, as usual.

Why do I keep hearing you mumbling about cost? This is a *hobby* . . . like sports cars . . . flying . . . blondes . . . and, as you know, the difference between a man and a boy is the price of his toy. You can add up all the components for yourself, but it is unlikely that you are going to have much going for under $2000. I counted up the claimed investments in hobby computing of about five hundred subscribers to *KB* and it

Computerized Satellite Tracking

-- the needed software

Satellite tracking — a subject that I would think could get pretty sticky for us non-whiz-kid math types. Bob Henson presents the subject in such a manner that the math seems almost incidental (i.e., he doesn't get bogged down in the details like many authors would have a tendency to do). Another neat feature of his article is the fact he offers some suggestions for modifying his BASIC program so that it can be rewritten and run on other BASIC interpreters. — John Craig.

Bob Henson WBØJHS
PO Box 605
Waukee IA 50263

To date, several articles have appeared in ham publications describing graphical techniques for calculating antenna aiming data for amateur and weather satellites. While these methods provide results that are accurate enough for most satellite communications purposes, the inconvenience involved in the preparation of the necessary charts and graphs is not particularly appealing, leaving one with the notion that there must be a better way. Those particularly adverse to the graphical approach will inevitably look to the application of the digital computer to relieve them of these computational chores. Formerly limited to a fortunate few who had access to large, expensive computers, the advent of the microprocessor and subsequent development of low cost hobby computer systems have put the computerized approach to satellite tracking within the reach of many.

Even with the computer hardware now available at an affordable price, one necessary element is still missing: namely, the software, or program, to perform the calculations. This article will describe such a program. While the intent is to provide sufficient background information so that the reader can modify and execute the program on any computer in any language that he might have available, a listing of a version written in BASIC will be presented, since it appears to be the current "standard" with hobbyist systems.

Without attempting any rigorous mathematical derivations, equations necessary to afford a solution will be presented. If desired, more detailed information on these equations can be gleaned from the references listed at the end of the article and from the many handbooks and textbooks dealing with spherical trigonometry. Since the program to be described is a minimal operating configuration, performing only the most basic tasks required by a tracking program, suggestions for extensions, modifications, and enhancements will be presented at the conclusion of the article.

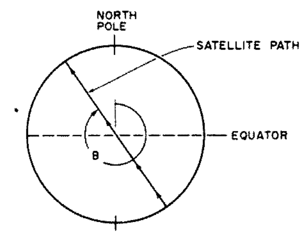

Fig. 1. Bearing of the satellite sub-point path at EQX (represented by the angle B).

Background

Several excellent articles have been published presenting the fundamental concepts of satellite tracking. Rather than reiterate the information in those articles, I will instead summarize only those orbital characteristics with which we need concern ourselves in developing a satellite tracking program. Those who need a "refresher" are urged to read the articles referenced at the end of this article.

To begin with, let's define the information that we want the program to calculate for us:

1) The time of each EQX (northbound equatorial crossing by the satellite sub-point). Satellite sub-point — the point on the Earth's surface that would be intersected by a line connecting the center of the Earth and the satellite.
2) The longitude of each EQX.
3) The azimuth (degrees clockwise from true North) of the satellite position with respect to the station

Elapsed Time (minutes)	Latitude (degrees)	Longitude (degrees)
0	0.0	0.0
2	6.13	1.79
4	12.26	3.60
6	18.38	5.48
8	24.49	7.46

Table 1. Latitude and longitude of OSCAR 7 at two minute intervals after an EQX at 0 degrees longitude.

versus elapsed time from EQX.

4) The elevation (degrees above the horizon) of the satellite position with respect to the station versus elapsed time from EQX.

5) The distance in statute miles between the station and the satellite versus elapsed time from EQX.

The orbital parameters of the satellite that we need to know in order to calculate this information is:

1) The altitude at which the satellite orbits above the Earth's surface. For OSCAR 7, this is approximately 910 statute miles.

2) The satellite orbital period in minutes (the number of minutes it takes the satellite to make one complete orbit about the Earth). For OSCAR 7, the orbital period is 114.9458 minutes.

3) The bearing of the satellite sub-point path at EQX (see Fig. 1). For OSCAR 7, this bearing is 348.23 degrees.

4) The difference, in degrees of longitude, of the satellite sub-point at consecutive EQXs. Each EQX of OSCAR 7 is 28.73625 degrees west of the previous EQX.

5) The time of the EQX of a reference orbit of the satellite. This can be obtained from reference data available from AMSAT or from one of the ham publications.

While most of the examples presented will be based on the orbital parameters of OSCAR 7, the program will be developed for general use for tracking satellites with the following orbital characteristics:

1) Constant orbital height (circular orbital pattern).

2) Constant orbital velocity.

3) Non-synchronous orbital pattern (the satellite sub-point is not stationary).

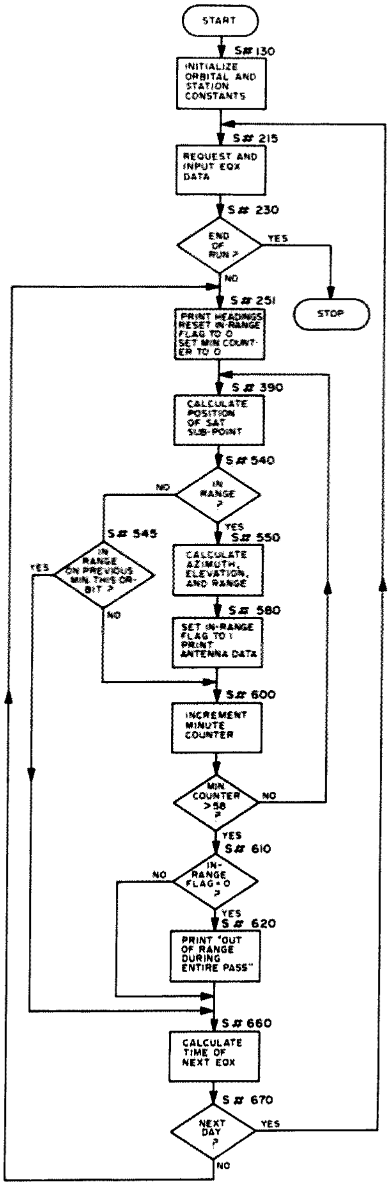

Fig. 2. A flowchart of the satellite tracking program.

Mathematics

The necessary equations to describe the orbital characteristics listed above are contained in the appendix. Without attempting any derivations or providing any lengthy explanations of the origins and ramifications of these equations, let's instead concentrate on what information the equations provide for us, and how we can utilize them in a computer program.

The first problem that we must tackle is that of pinpointing the location of the satellite sub-point at a given instant in time, knowing only the orbital characteristics of the satellite and the location of the satellite at a reference moment in time (such as at EQX). Equations 1 and 2 give us this means. It should be noted that the latitude of the satellite sub-point versus time depends only on the orbital constants of the satellite, and is not dependent on the longitude of the sub-point at EQX. However, the longitude of the satellite sub-point with respect to time is dependent on the longitude of the sub-point at EQX.

Equations 3 and 4, derived from general equations 1 and 2, are applicable only to OSCAR 7. Table 1 is a com-

pilation of the latitude and longitude of the OSCAR 7 sub-point versus elapsed time from an EQX at 0 degrees longitude. As previously stated, the latitude of the satellite sub-point versus time can be taken directly from the table regardless of the longitude at EQX. However, to determine the longitude of the satellite sub-point versus time, we must add the longitude of the sub-point at EQX to the value given in the table. For example, the longitude of the satellite sub-point 26 minutes after an EQX at 43 degrees longitude is 60.03 degrees (from the table) plus 43 degrees, equaling 103.03 degrees. The latitude at that moment, read directly from the table, is 75.48 degrees.

Now that we have the means of determining the position of the satellite at any given moment in time, we can employ equation 5 to find the angular separation in degrees of great circle arc between the satellite sub-point and the station for which we are calculating the antenna aiming data. While this intermediate result is of no value as it stands, it is required for the remaining calculations.

Equation 6 gives us the bearing in degrees from true North of the satellite sub-point from the station. Equation 7 then gives us the final piece of information we need for accurately aiming the antenna — the elevation in degrees from horizontal that the satellite appears above the horizon. The final equation, equation 8, allows us to calculate the distance in statute miles between the station and the satellite.

In all cases, the unit of distance is statute (not nautical) miles, and the angular units are degrees rather than radians. Equations 1, 2, 5, and 6 are applicable to any satellite with the previously mentioned general orbital characteristics. Equations 3 and 4 are specialized versions of equations 1 and 2, applicable only to OSCAR 7. As presented, equations 7 and 8 are also applicable only to

OSCAR 7. However, they can easily be modified for use with other satellites by replacing the constant 4867, which represents the sum of the Earth's radius and the altitude that the satellite orbits above the Earth's surface. For example, to modify the equation for a satellite that orbits 950 miles above the Earth's surface, simply replace the constant 4867 with 4907, the sum of the Earth's radius (3957 miles) and the orbital height of 950 miles.

While these mathematical manipulations are not exactly formidable, they are certainly not trivial. A great deal of number crunching is necessary to calculate antenna aiming data for just one moment in time, and even with the aid of a scientific calculator, the task of calculating an entire day's worth of aiming data would take hours of tedious effort. Fortunately, solving the equations is a snap for the digital computer.

Flowchart

Unfortunately, computer technology has not yet evolved to the point where computers program themselves. While eagerly awaiting this development, we are faced with devising our own problem-solving algorithms, and with the often tedious task of programming and debugging the software implementation of these algorithms.

Even with an adequate set of mathematical equations to solve the problem, such as those just discussed, they must still be arranged into a logical and orderly framework from which the computer can proceed. This is often an iterative process, a matter of trying many ideas, and determining by trial and error the most expedient (not necessarily the best) method of realizing a solution. Perhaps the easiest way of explaining the final choice of the algorithm is with a flowchart. A flowchart for the satellite tracking program is depicted in Fig. 2. Statement numbers have been affixed to the flowchart symbols, referring to the BASIC program statements of the listing in Fig. 3.

Beginning at statement 130, the fixed data for the program is initialized. Note that the latitude and longitude of the satellite sub-point versus time for an orbit with an EQX at 0 degrees longitude is stored in the program in two arrays (or matrices) and initialized at this time in statement 185. At statement 220, the computer asks for data for the reference pass (time and longitude of the first EQX of the day, as published monthly in *73* and other sources). If a 99,99,99 is typed in at this time, the program will halt (statement 230).

At statement 340, the in-range flag and minute counter are reset to 0. The in-range flag is a means by which the program can keep track of whether the satellite was ever within range of the station during a particular orbit. The minute counter is a register where the program remembers the minutes that have elapsed since EQX.

Beginning at statement 390, the program calculates the position of the satellite sub-point for the time stored in the minute counter. If the satellite is in range, antenna aiming data is calculated and printed (statement 550) and the in-range flag is set to 1, which will later remind the program that the satellite has been in range during at least one moment during the orbit. If the satellite is not in range, the program checks to see if it was in range during a previous minute of that particular orbit. If so, it knows that the satellite will not come into range again until the next orbit, and it branches to statement 660. If the satellite has not been in range during a previous minute of the current orbit, the program branches to statement 600, and after incrementing (adding 1 to the current value) the minute counter, checks whether over 58 minutes have elapsed since EQX. If so, the program prints an appropriate message and calculates the time of the next EQX. If 58 minutes have not elapsed, the program loops back to statement 390 to calculate the position of the satellite sub-point at the next checkpoint in time (two minute intervals in this case).

At statement 660, the time of the next EQX is calculated. If that time is still in the current day (before 24:00:00 GMT), the program loops back to statement 340 and repeats the entire process for the next orbit. If the next EQX occurs during the next day (after 24:00:00 GMT), the program loops back to statement 220, giving the

Fig. 4. Sample output from the satellite tracking program.

APPENDIX

Equation 1

A general equation for calculating the latitude of a satellite sub-point versus elapsed time from EQX.

$Lat(T) = \sin^{-1}(\cos(\text{sub-point bearing})\sin(360T/P))$

T = the elapsed time in minutes from EQX

P = the satellite orbital period in minutes

Sub-point bearing = the bearing of the satellite sub-point path at EQX (see Fig. 1)

Example — Given a satellite with an orbital period of 100 minutes, and a sub-point path that has a bearing of 330 degrees at EQX, find the latitude of the sub-point 10 minutes after EQX.

$Lat(10) = \sin^{-1}(\cos(330)\sin(360 \times 10/100))$

Lat(10) = 30.60 degrees North

Equation 2

A general equation for calculating the longitude of a satellite sub-point versus elapsed time from EQX.

$Long(T) = \cos^{-1}(\cos(360T/P)/\cos(Lat(T))) + (0.25T) + L_0$

T = the elapsed time in minutes from EQX

P = the satellite orbital period in minutes

Lat(T) = the latitude of the satellite sub-point as calculated with Equation 1

L_0 = the longitude of the satellite sub-point at EQX

Example — Given a satellite with an orbital period of 100 minutes, and a sub-point path that has a bearing of 330 degrees at EQX, find the longitude of the sub-point 10 minutes after an EQX at 100 degrees longitude.

$Long(10) = \cos^{-1}(\cos(360 \times 10/100)/\cos(30.60)) + (0.25 \times 10) + 100$

Long(10) = 122.46 degrees

Equation 3

An equation for calculating the latitude of the OSCAR 7 sub-point versus elapsed time from EQX.

$Lat(T) = \sin^{-1}(0.9790\sin(3.1319T))$

T = the elapsed time in minutes from EQX

Example — 10 minutes after EQX the latitude of the sub-point would be:

$Lat(10) = \sin^{-1}(0.9790\sin(3.1319 \times 10))$

Lat(10) = 30.590 degrees

Equation 4

An equation for calculating the longitude of the OSCAR 7 sub-point versus elapsed time from EQX.

$Long(T) = \cos^{-1}(\cos(3.1319T)/\cos(Lat(T))) + 0.25T + L_0$

Lat(T) = the sub-point latitude as calculated with Equation 3

T = the elapsed time in minutes from EQX

L_0 = the longitude of the satellite sub-point at EQX

Example — 10 minutes after an EQX at 20 degrees West longitude, the sub-point longitude would be:

$Long(10) = \cos^{-1}(\cos(3.1319 \times 10)/\cos(30.590)) + 0.25 \times 10 + 20$

Long(10) = 29.569 degrees West

---

operator a choice of requesting data for another day's orbits or for stopping the program.

Program Listing

The listing in Fig. 3 has been thoroughly annotated. The following comments should provide additional insight into the inner workings of the program and will hopefully expedite the process of implementing the program on other computers:

1) All the modifications required to use the program for calculating tracking information for other satellites are made in lines 130-180 and 800-830. Station location data is entered at lines 170 and 180.

2) Few will probably wish to leave the program exactly as it is once they get it running on their machine. An attempt has been made to keep the program structure modular so that new features can be easily added. Some of the following modifications and enhancements that might be made are:

a) Print out in local time rather than GMT (or UCT).

b) Print out orbital data in smaller or larger time intervals than 2 minutes.

c) Print out when both the local station and another station of interest are within range of the satellite.

d) Calculate the Doppler shift of the received signal.

e) Suppress printout during specified hours of the day.

f) Interface the program to an assembly language program to perform real-time control of the antenna during satellite passes, providing automatic operation.

3) Anyone who has had experience in trying to implement a "canned" program on any computer system has undoubtedly been faced with the task of converting certain non-standard code of the "canned" program to code that his particular system would accept. This consideration applies to both large and small systems, even in languages such as FORTRAN and COBOL, where there are generally accepted standards to promote program portability. Since the microcomputer field is still in its infancy, it should come as no surprise that the BASIC interpreter available from any particular manufacturer is more than likely different in at least some respects from the BASIC interpreter supplied by any other manufacturer. To my knowledge, there is not yet a standard on what features comprise the "4K", "8K", "12K", and "extended" BASIC interpreters being marketed by the various manufacturers and systems houses.

Without making a thorough study of the BASIC interpreters available on the market today, I would guess that the program as listed in Fig. 3 will run with very few modifications on most of the interpreters billed as "12K" or "extended." To execute the program on the more elementary interpreters, some or all of the following modifications will be required:

a) Delete the latitude and longitude tables from the program and add subroutines to directly calculate the satellite sub-point latitude and longitude each time it is required. The essence of the required mathematics for this conversion is contained in equations 1 and 2 in the appendix. The Q and V matrices can then be eliminated from the program, allowing the program to be executed by interpreters that cannot support matrix variables. This modification will have the effect of minimizing the amount of memory required, but will measurably slow down the execution of the program.

b) Substitute iterative routines and approximations for the library trig subroutines in the program. There are a number of handbooks on the market that describe techniques for performing trigonometric and other transcendental functions on simple four function calculators. These techniques can be utilized in developing simple subroutines to provide approximate function solutions that will be accurate enough in this application. This will allow the program to be executed on machines that cannot support trig functions.

c) Delete the "PRINT USING" statements from the program. They are used to format the output in a particular fashion, but are certainly not essential to the program. The output can then be formatted in

Equation 5

An equation for calculating the angular separation of a station location and a satellite sub-point.

$D = \cos^{-1}(\sin A \sin B + \cos A \cos B \cos L)$

D = the angular separation in great circle degrees of arc between the station location and the satellite sub-point

A = the latitude of the station in degrees

B = the latitude of the satellite sub-point in degrees

L = the station longitude minus the sub-point longitude. If the algebraic difference is outside of the range of -180 to +180 degrees, add or subtract 360 degrees, whichever will result in a value in the range of -180 to +180 degrees.

Example – Given that the station is at 39 degrees N. latitude and 77 degrees W. longitude and the satellite sub-point is at 23 degrees N. latitude and 63 degrees W. longitude, the angular separation is:

$D = \cos^{-1}(\sin 39 \sin 23 + \cos 39 \cos 23 \cos 14)$

D = 19.95 great circle degrees

Equation 6

The equation for calculating the true bearing from a station to a satellite sub-point.

$\text{Bearing} = \cos^{-1}((\sin B - \sin A \cos D)/\cos A \sin D)$

A = the latitude of the station in degrees

B = the latitude of the satellite sub-point in degrees

D = the angular separation of the station and sub-point as calculated in Equation 5

Bearing = degrees clockwise from true North of the position of the satellite sub-point with respect to the station. If the value of L in Equation 5 was negative, the bearing is (360 - bearing).

Example – For the conditions in the example of Equation 5:

$\text{Bearing} = \cos^{-1}((\sin 23 - \sin 39 \cos 19.95)/\cos 39 \sin 19.95)$

Bearing = 139.23 degrees from true North

Equation 7

An equation for calculating the antenna elevation for tracking OSCAR 7.

$E = 90 - \tan^{-1}(4867 \sin D/(4867 \cos D - 3957))$

D = the angular separation calculated in Equation 5

E = the angle above the horizon of a straight line between the station and the satellite

Example – For the conditions in the examples of Equation 5 and Equation 6:

$E = 90 - \tan^{-1}(4867 \sin 19.95/(4867 \cos 19.95 - 3957))$

E = 20.41 degrees

Equation 8

An equation for calculating the distance from a station to OSCAR 7.

$M = (4867 \cos D - 3957)/\cos(90 - E)$

D = the angular separation calculated in Equation 5

E = the elevation calculated in Equation 7

M = the distance in statute miles between the station and the satellite (its true position, not the sub-point)

Example – Using the same conditions as for the examples in Equations 5-7:

$M = (4867 \cos 19.95 - 3957)/\cos(90 - 20.41)$

M = 1771.93 miles

---

other ways by the user.

Conclusion

The intent of this article has been to present sufficient information on a satellite tracking program so that the interested individual can implement the program on any computer he might have at his disposal. While the version presented here is admittedly a minimal configuration, the additions or refinements to enhance operating convenience should not be difficult. I will gladly assist anyone who encounters difficulties if the questions that arise are submitted along with an SASE. ■

Building the Polymorphics Video Board

-- the voice of experience

Glen Charnock WB6JKM
864 Palomar Way
Oxnard CA 93030

For someone who is primarily a software-oriented person, I seem to do a lot of hardware building. In September, 1974, I started building TVT-I. I got it working in December and had it connected to my Altair 8800 in December, 1975. A friend, also with an Altair, built TVT-II and it was so much faster and better designed that I sold my TVT-I and built a TVT-II. I didn't keep detailed notes on the construction of these two projects, but I learn from my mistakes. When another friend showed me his Polymorphics video board, I knew I was doomed. This video board plugs directly into the Altair or IMSAI bus, eliminating a large boxfull of power supply, TVT-II, and cables, and frees the parallel I/O port I used with the TVT-II. This time I kept notes on the subject. The kit is of good quality and there should be no more than the normal problems putting it together; nevertheless, there are some pitfalls. This article will explain the ones that I encountered and how to solve them.

The video board appears to the program to be a block of random access memory which is constantly displayed on your monitor or modified TV. The display has sixteen lines which may be either 32 character lines ($185) or 64 character lines ($210). The 32 character lines will probably work with a modified TV which has a bandwidth of 2.5 MHz, but the 64 character lines may require a monitor, as they need a bandwidth of 5.5 MHz. The memory uses 91L11 chips and acts as a normal memory. It can be used for program or data storage in addition to its normal uses. Data may be entered into any of its memory locations at any time, giving the capability of scrolling, paging, columns, fixed format entry, or any other display mode you would like to use. This flexibility requires suitable programming – more on this later!

An 8-bit parallel input port is built into the video board so that a keyboard may be attached, thus giving both input and output from one board. Unfortunately, there is no corresponding status port for this input port, so the program must check the data to see if it has changed in order to know when new data is available – again, more programming overhead.

The 6572 character generator chip provided with the kit gives 128 ASCII characters, including upper and lower case, numbers, and special symbols. Lower case Greek letters print in place of the ASCII control characters. Other chips in the same series may be substituted, giving different special symbols instead of the Greek letters. The graphics display is handled external to the 6572 chip. The character space is broken up into six spaces – three rows of two blocks each, giving 64 possible graphics characters. The blocks cover the entire character space so that the entire screen may be made light with no spaces between characters.

Buying The Kit

When I decided that their kit would satisfy my needs, I called Polymorphics and asked them to send me a kit.

I've learned several things from the boards that I've already built. I use sockets for all ICs (sockets come with the Polymorphics video board) and I test all of the parts that I can test. These two things can save hours of time later in the project when it doesn't work.

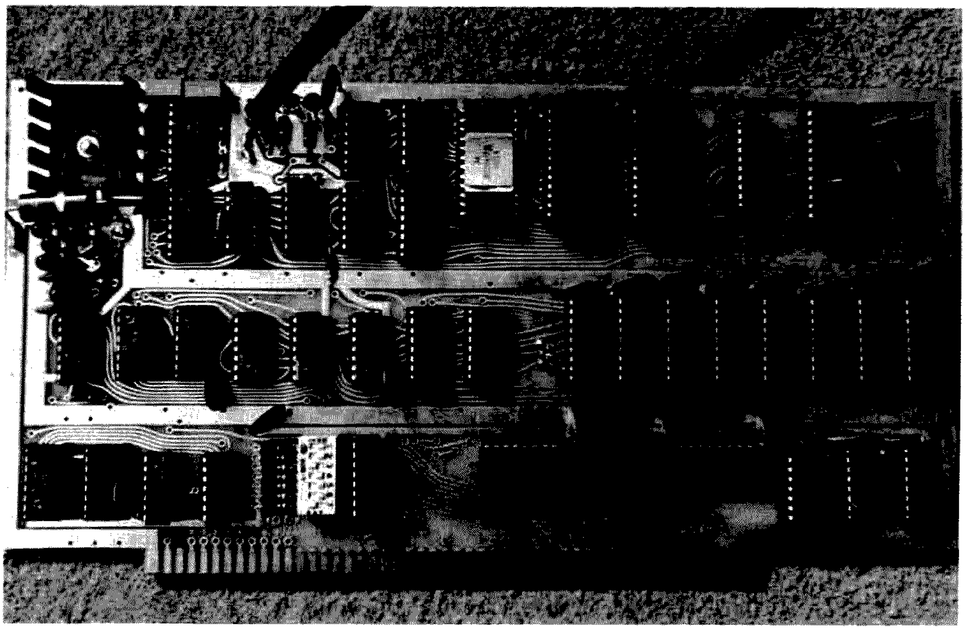
The first thing I did when I opened the box was to look at the instruction book. This is an impressive manual of about 72 pages and covers assembly, theory, troubleshooting, and software. The section on troubleshooting is especially impressive as many kits have no such section. Polymorphics devoted 16 pages to troubleshooting, arranged in a logical manner. Hopefully you won't need it (I didn't), but it's nice to know that it's there and reading it will help give you a better understanding of the circuits involved.

Building The Kit

The first part of kit-building is checking the parts supplied against the parts list. I was missing a 27 pF capacitor and a 150 Ohm resistor, but it turned out that neither part was used in the kit. A 1N759 12 V zener diode was also missing, but a 78L12 was supplied instead. An extra 10 uF electrolytic capacitor was included and was used in the kit.

Having determined which parts were supplied, the next

step was to test all that I could. It is much easier to find a shorted capacitor, for example, when you have not yet mounted it than it is to find it when you discover that your board doesn't work! The resistors supplied with my kit were all within tolerance, but I found that one end of one 10k Ohm trimpot was open. I was able to use it for R22, so it caused no problem. I checked the capacitors for shorts and observed the charging of those over .01 uF. All capacitors tested good. All diode and transistor junction resistances (forward and backward) were good. By inspection I found a solder bridge on one of the ICs. This is not uncommon and can cause a lot of grief if it isn't found before the IC is mounted.



Getting It All Together

The assembly instructions are aimed toward the person who has had some prior kit-building experience. A drawing of the board is given showing the locations of the various parts. Each part is listed with a space to check as each is soldered in place. The drawing in my manual was smeared in places so that I couldn't read the parts labels. I was able to get the needed information from a friend with a Polymorphics video manual with a clear drawing. There were also two pages missing from my manual which I was able to copy from his. Further confusion can arise from C25, which is labeled .01 uF on the schematic but is given as 4700 pF in the assembly instructions (4700 is correct). The polarity is not given for one of the electrolytic capacitors and is shown reversed on the schematic for one of the others. It may be obvious to everyone but me, but I still think that a note should be included telling which way to orient the trimpots so that they can be adjusted while the board is in operation. I also think that instructions on connecting the video output cable should be included.

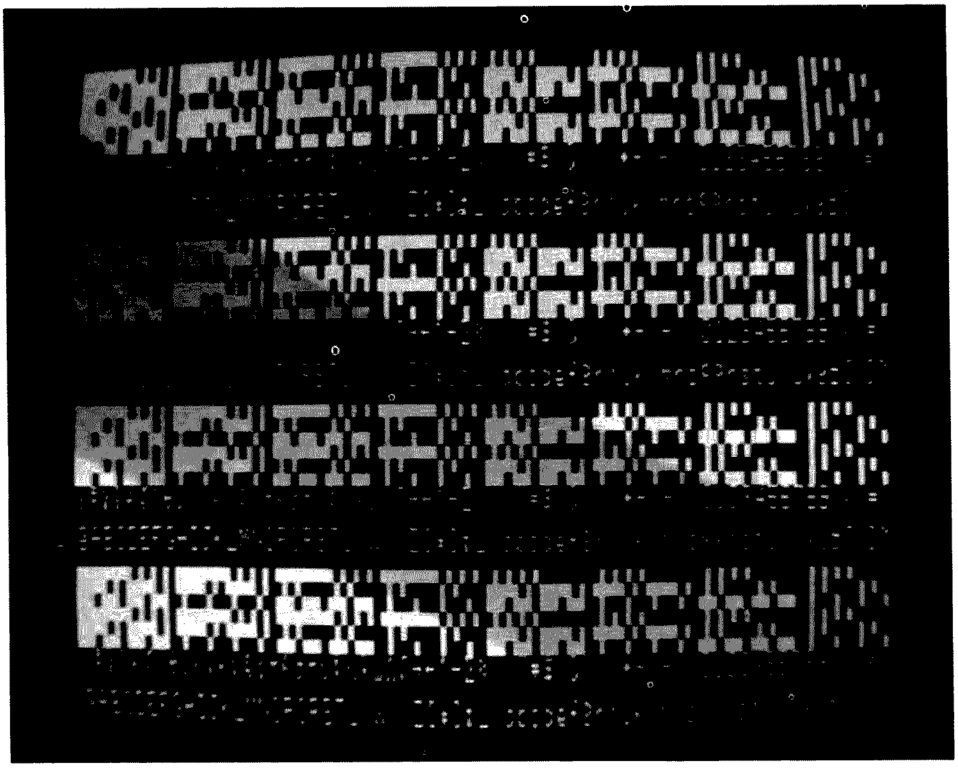
In all, construction time was probably well under 10 hours, but it is hard to tell when the time available to work on it comes in blocks of 30 minutes or less. In any event, the moment of truth finally came. I plugged it in and turned power on. A few quick adjustments of the horizontal and vertical controls on my monitor and voilà – a screen with funny-looking characters on the left side of the screen and wavy lines running from top to bottom. The characters didn't look too good either. A quick voltage check: Yipes! 6.6 volts instead of 5.0. Replacing the 7805 regulator brought the voltage down to an acceptable 5.06 volts. I decided that it is worthwhile to test voltage regulators also! Somewhat afraid that, after the 6.6 volts, I now had a board of write only memory, I tried again. No ripple this time and the voltage was good, but the characters were still all at the left side of the screen and still looked funny. I could enter characters or change them but they looked like negative images. Enter my friend again. I had used twinlead to connect the board to my monitor because I didn't have any coax handy. (No cable is supplied with the kit.) My eagle-eyed friend pointed out that I had reversed the connections to the monitor, thus reversing the video. This also caused the monitor to sync on the first white square (black in the negative image) on each line, thus preventing me from centering the display. Changing the cable restored a positive image and fixed the sync. The board now worked just fine with respect to hardware.

Apparently there is a problem with some monitors due to the fact that the video board operates at 17.094 kHz, which is above the normal horizontal sweep frequency. Instructions are given to lower the board's frequency if required. It is also possible to use an onboard crystal to obtain any desired sweep frequency. Normally the signals are divided down from the 2 MHz clock on the CPU board. This modification was not needed with my Sanyo VM-4092 monitor.

Software – The Last Pitfall

Because the board is so versatile, the software to control it is complex and lengthy. For paging, the control software must determine where the character is to be put, control a cursor if desired, and watch for end of page. Line feed and carriage return instructions must be intercepted and handled as well as any optional commands you wish to implement, such as backspace or backline, etc. One problem which could have been avoided is the fact that the board looks at the most significant bit to determine whether to display an ASCII character or a graphic character. If the bit is a 1, the ASCII is displayed. Most packaged software, such as MITS BASIC, will mask this bit to a zero so the video control software must also fix this bit.

Polymorphics includes a listing of a program to control their board. It allows for input from their keyboard using interrupts to determine when data is valid. The program offers quite versatile control of the display. Home, erase, right, left, down, delete character, insert character, etc., as well as optional paging or scrolling, are available under software control. The video control routine is 455 bytes long and is given as an assembly listing in hexadecimal. It uses memory locations Ø through 44 and 1DØØ through 1E83. The board is assumed to start at memory location 88ØØ hex. This is a



lot more overhead than a simple I/O port which might use 20 bytes. The best idea is to put the driver routine in PROM. Another disadvantage is that this video output will not be compatible with other packaged software such as MITS BASIC, although such programs can be modified to call the video driver.

Another program listing is included in the manual. This one plays the "game" of LIFE. LIFE loads into memory locations Ø through Ø1Ø6 hex and also uses blocks of memory starting at 3ØØ and 8ØØ hex.

Since I work in octal, don't have an assembler operating, and these routines overlay my control programs, I don't have either of them loaded yet. Both are well-documented with comments, though neither appears to use structured program techniques. It should not be difficult to get them running.

Summary

Overall, the kit seems well-designed. Except for a bad part (the voltage regulator) and my own stupidity (the reversed video cable), the board would have worked the first time. Even if it hadn't, the troubleshooting section seems well thought out and requires no test equipment but a voltmeter and your monitor. I built it and I'm glad I did. ■

RTTY Goes Modern

-- using microprocessors

Robert C. Brehm WB6QFA
1095 Sherman Avenue
Menlo Park CA 94025

Today's RTTY amateur has available a choice of equipment and techniques that allow him to develop sophisticated radioteletype-computer links which were only dreamed of several years ago. Moreover, with the ever-increasing usage of RTTY on VHF repeaters, the feasibility for radio-linked computer programming from a central computer is not only plausible, but is on its way to becoming a reality.

This article provides a general introduction into amateur RTTY as well as a chronological background of RTTY developments over the past 15 years. This article should familiarize non-RTTY amateurs and computer hobbyists with the early developments and how they have influenced the current state of the art. Finally, I have taken the liberty of predicting what the marriage of microprocessors and RTTY will bring in the future. So pull up your easy chair, relax, and follow me as I take you down the evolutionary path of amateur radio TTY.

Amateur RTTY – What Is It?

Amateur radioteletype, or RTTY for short, started in the early 1950's when many of the military surplus teleprinters and associated equipment became readily available at reasonable prices. In addition, in 1953, the FCC allowed amateurs to use RTTY on all frequency bands above 3.5 MHz.

In the early days of RTTY, activity on the ham bands was split between groups who primarily worked the frequencies below 30 MHz and those who were content to use VHF frequencies. One group desired long distance RTTY communication while the others used RTTY for local net-type operation.

In those days RTTY was, and still is, transmitted in one of two ways on frequencies below 30 MHz. The first method, called frequency shift keying, or FSK, involves changing the carrier frequency each time a mark or space pulse is encountered during a character's transmission. Using FSK, a constant carrier is transmitted for a mark pulse, with a space pulse causing the carrier to shift down by 850 Hz. More recently, common practice has changed the shift to 170 Hz due to the increasingly crowded ham band signals which cause interference within the wider 850 Hz shift. The other common method of RTTY transmission utilizes audio frequency shift keying, or AFSK. With this method, a pair of audio tones is fed into a single sideband system, utilizing a well-suppressed carrier and operating in the lower sideband mode. The shift of the audio tones, usually generated with 2125 (mark) and 2295 (space) Hz signals, again presents a 170 Hz signal to a copying receiver. On the receiving end of things, both FSK and AFSK generated signals sound exactly alike, and it is unlikely that you could tell them apart. On VHF, the audio tones are usually fed into an AM or FM transmitter using either 850 Hz or 170 Hz shift, depending upon which shift is being used in the particular area.

The AFSK signal generation used in RTTY is similar to the AFSK used in most computer-telephone-modem links except for the frequencies of the tones. Another obvious difference is the transmission media, which is radio waves instead of telephone wire pairs. The RTTY speed of 60 wpm (45.5 baud) is also somewhat slower than conventional modems which operate at 110 or 300 baud. The code used for RTTY is the common 5 level Baudot code which has 32 characters in the "letters" mode and another 32 in the "figures" mode; however, not all characters are used.

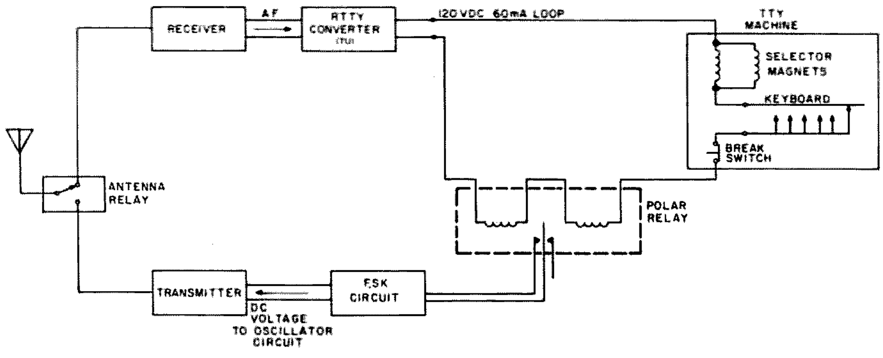


Fig. 1. Early RTTY FSK system.

The similarity between modems used on computers and modems for RTTY, which are called terminal units, also exists on the reception end. Most common of the terminal units are ones with tone selective filters which respond to 2125 and 2295 Hz tones taken from the receiver speaker terminals. Additional circuitry is often incorporated to compensate for selective fading of signals and space-only or mark-only copy. The terminal units basically function as tone decoders which drive a tube or transistor keying stage adjusted for 60 mA of printer loop current. A typical receiving system is shown in Fig. 1.

In this setup, the converter (TU) connects to the audio output of the receiver, and modulates (keys) a 120 V dc "loop" adjusted for 60 mA of current required by the selector magnets of the teleprinter. The keyboard of the teleprinter is also connected in series with the loop supply; consequently, whenever a key is depressed, it breaks the loop in a predetermined sequence, which causes the printer to print that character. In addition, when the transmitter is on, depressing a key will cause the Baudot encoded character to be transferred through a polar relay into an AFSK generator which can modulate the transmitter.

Transmitting and receiving are conceptually easy to understand although, depending upon the accessories that are hooked into the system, the switching circuitry can get quite complicated.

Many amateurs started with simple setups as shown in Fig. 1; however, they soon learned that adding accessories could significantly enhance both receiving and transmitting operations. Early in the RTTY game, most additions to the RTTY station were mechanical in nature. Paper tape perforators and transmitter distributors (tape readers) were probably the first added luxuries. These items allowed you to punch a tape for transmission later at full speed. It is common practice to punch a tape while the other person is sending to you, so that when he is done, you can immediately start sending back to him. Another mechanical feature which proved to be quite popular was the stunt box available in the Model 28 machines. This mechanism allowed the printer to decode or "recognize" certain characters or combinations of characters in such a manner that a switch closure (or opening) could take place. This feature, in conjunction with an option called answer-back (part of an item called a WRU or who are you?), allowed a person's machine to answer or transmit back a programmed message when queried with a preprogrammed recognition sequence. Some Model 28s are even equipped with back space and reverse line feed so you can "roll up" what has already been typed. Imagine coming home to a spindle of paper all rolled up and printed!

Many of the above mechanical features were coupled with a very popular option called autostart, which is short for automatic starting. This feature allows your TU to be activated by a steady mark tone lasting a given duration (usually about 3 seconds or more). Although employed to a limited extent on the low bands, autostart TTY is used quite extensively between club or net members using the VHF bands for local communications. The principle involved with autostart is simple. As an example, suppose you have a receiver monitoring your favorite channel and while you are out at a swapmeet, one of your friends calls you on the radio to leave you a message. When he transmits a continuous mark tone for 3 seconds, your TU responds by turning your printer motor on and subsequently prints your friend's message and shuts itself off again ... all automatically. When you arrive home, the message is there waiting to be read. This feature is obviously very useful, and many amateurs monitor a given frequency 24 hours per day in order to be in constant communication with their friends.

Glossary

POLAR RELAY:	*A springless relay built by winding a magnetic core with two equal but opposite windings. The armature stands theoretically in the middle of the two windings. This kind of relay permits the operation of a RTTY circuit that has a current flow in one direction for mark and in the opposite direction for space.*
POLAR SIGNALS:	*Signals in which the current in the transmission line is reversed in polarity in changing from marking to spacing.*
NEUTRAL SIGNALS:	*Signals sent in the form of direct current pulses for marks and an absence of current for spaces.*
REGENERATIVE REPEATER:	*A circuit which samples incoming signal pulses and retransmits them with perfect timing and no distortion.*
DIDDLE:	*Automatic transmission of letters or figures characters by the TU if no characters are ready for transmission (most often used with a FIFO or memory).*
BAUDOT:	*Five level code used primarily by amateurs in RTTY communication. Only code allowed by FCC without special waiver.*
ASCII:	*American Standard Code for Interchange of Information (commonly used in computers).*
TU:	*Terminal unit or amateur RTTY version of a modem.*
QSL:	*Written acknowledgement of two-way radio communication.*
FIFO:	*First In, First Out stack. Used for storing data for retransmission (communication applications).*

The 1960's

These mechanical marvels were quite the state of the art in the mid and late 1950's. But around 1960, with the ever-increasing use of the transistor by amateurs, many of the functions previously performed by mechanical means were being performed by electronic circuits.

Probably one of the first mechanical items to give way to electronic circuitry was the ubiquitous polar relay. This relay was used in the polar circuitry of terminal units where current flowed in one direction for space and in the opposite direction for mark. Thus the relay could key a local loop supply for a teleprinter when driven by tone decoders. This electronic "advancement" in modern technology, utilizing such components as SCRs and switching transistors, got rid of noisy clicking relays which often got out of adjustment or were plagued with dirty contacts. More importantly, however, it also sparked the beginnings of the evolution of solid state technology in RTTY applications.

It is interesting to digress for a moment and reflect upon the paths taken in the "evolution" I have just mentioned. First of all, it was a dual affair, with the VHF RTTY folk applying solid state technology to AFSK methods and terminal units in the early 60's. The other concerted effort was made by the lower frequency RTTY men who seemed to lag behind technologically, prob-

ably due to the more severe reception problems associated with static noise, signal fading, and changing atmospheric conditions. The progress of both groups can be put into perspective by observing Fig. 2, a time line showing RTTY evolution derived from a study of articles published in *73, QST, CQ, Ham Radio,* and the *RTTY Journal* during the 60's.

It is easy to draw several conclusions from Fig. 2. First, we observe that transistorized TUs are introduced early in the 60's but are used primarily on VHF where receiving conditions are almost identical to modem reception over telephone lines. On the other hand, FSK terminal units were still built primarily with tube circuits without bandpass filters but using clunky polar relays. However, in 1965, FSK RTTY really got a push due, in most part, to a one-man effort by Irv Hoff, who published no less than ten articles in *QST* covering all aspects of RTTY. He also shared the design credit for the Mainline TT/L FSK demodulator which, for FSK, was the state of the art even though it used tubes. During the rest of the 60's, solid state and digital technology continued to be used primarily in VHF with the introduction of such items as a digital Selcal (selective calling unit similar to a mechanical stunt box), crystal controlled AFSK generators, and IC RTTY converters. In contrast, tube circuitry was still being used in the TT/L-2, an improved TU for LF described in a 1969 *QST* article. However, autostart techniques were catching on in the LF spectrum and diode FSK circuits were in common use.

Overall, it was rather apparent, during the 60's, that VHF RTTY amateurs were closer to using state of the art digital technology than their LF RTTY compatriots. The reason for this difference is not quite clear, although it may be due to the fact that VHF RTTY amateurs, by virtue of continually talking (printing) with the same people on net frequencies, generated more ideas and techniques than the LF hams who tended to have less frequent contacts in a more or less hit and miss fashion. However, in the 1970's the technological difference between the two groups has become less and in fact may have become equal.

1960	
	Polar relays used extensively
	Tube converters for low frequency (LF)
1961	
	Simple VHF transistor TU
	Transistorized AFSK
1962	
	Garden City TU (LF)
	FSK without polar relays
	Introduction of bandpass audio filters for RTTY
1963	
	Chemical City TU (LF, mark only, space only copy)
1964	
	Crystal controlled FSK
	More transistorized TUs – VHF with autostart
1965	
	UJT AFSK OSC – VHF
	RTTY articles by Irv Hoff
	FSK with SSB transmitters used extensively
	Mainline TT/L FSK Demod (First good LF TU using bandpass filters and all other previous TU features and new innovations – tube TU!)
1966	
	Diode FSK circuits
	High performance RTTY filters
1967	
	Autostart RTTY – low frequency
	More solid state VHF TUs and AFSK gen.
1968	
	First RTTY Selcal introduced – digital ICs – VHF
1969	
	Mainline TT/L-2 – improved TU for LF (Tubes)
	IC RTTY TU and AFSK (ICs introduced to RTTY – VHF)
	Crystal controlled AFSK – IC technology

Fig. 2. RTTY Evolution – 60's.

The 1970's

The 1970's have brought us not only a digital revolution in consumer and industrial products, but also in RTTY, both for low frequency and VHF application. Fig. 3 illustrates this evolution in both areas of RTTY operation.

In the 70's, LF FSK circuitry quickly began to catch up with VHF RTTY circuitry. In 1970, the ST-3 and ST-5 terminal units were pioneered by Irv Hoff. Although designed primarily for VHF, they have been used extensively for LF also. In 1971, the ST-6 was born. This TU represents a solid state attempt to incorporate the circuitry developed in the TT/L-2 in the late 60's. It incorporated mostly op amps of the 709/741 series. Even today this TU is the most popular and widely used on the LF bands.

Very few major technological differences have taken place in LF RTTY TU technology since the advent of the ST-6. Most changes have involved accessories which interface with the ST-6 and provide more convenient operation. In 1971, speed converters using discrete components were introduced, as were preprogrammed digital message generators. In 1973, a crystal controlled digital audio synthesizer was described for AFSK generation with SSB transmitters. 1973 also brought several new accessories to the RTTY community, including video displays for Baudot, digital keyboards, digital autostart units, and Morse code to RTTY converters using discrete TTL circuits. 1974 was also a good year for technological developments in digital LF RTTY and the introduction of UARTs in RTTY circuitry.

Lest we not forget VHF during the 1970-74 period, it should be mentioned that the phase lock loop (PLL) was used in several TU designs taking circuitry ideas modeled after the PLLs used in computer modems.

It was in 1975, however, when the RTTY technology really exploded, just shortly after the introduction by MITS of the Altair 8800 microcomputer. In 1975, several articles described programmable RAM message

Year	Development	Notes
1970	Mainline ST-3,4	VHF TUs of modern design
	Mainline ST-5	
1971	Mainline ST-6	First good low band TU
	Digital MSG gen.	
	Speed Converters	Digital accessories come into wide use
	Digital AFSK gen.	
1972	PLL TU-VHF	PLL technology used
	Audio digital synthesizer	
1973	Hal video display	
	Digital keyboards	
	Morse to RTTY Converter	
	Digital autostart	
1974	Prom memory for RTTY ID	
	RTTY MSG gen.	
	Using UART	
1975	MITS introduces Altair	
	Programmable RAM MSG gen.	
	UT-4 (FIFO)	
	PLL TU	
	Solid state TTY keyboard	
	uP control of RTTY STN	
1976	DT-600 Digital ST-6	
	Hal MP unit	Morse to RTTY – uP
	Digital Time Clock	ASCII/BAUDOT
	Baudot/ASCII	WACC Winner – RTTY Station
	Digital Selcals	
1977	RTTY used with uP	
	Intelligent terminals	
	uP control of repeaters	
	uP controlled RTTY stations – wide use	
	Computer oriented repeaters with A/D converters for time, weather, termperature, etc.	
1978	Universal magnetic tape use for RTTY	
	uP controlled receivers and transmitters	
1979	Floppy disks and RTTY joined	

Fig. 3. RTTY Evolution – 70's.

generators. Also UARTs and FIFOs were becoming very popular among the LF gang (principally those monitoring 3612.5 MHz on the West Coast). It finally looked like LF and VHF techniques had caught up with each other! In late 1975, we began to observe the influence of microprocessors as evidenced by several articles which outlined microprocessor controlled RTTY stations both on VHF and LF.

This exciting trend has continued to accelerate at an increasing pace as the availability of hardware and software technology becomes more widespread. Hal Communications has introduced an 8080 based RTTY terminal; digital Selcal circuits are springing up everywhere; ASCII to Baudot and Baudot to ASCII code converters have been written up in several magazines with commercial units now available; and, to top it all off, the grand prize winner at the World Altair Computer Conference was a computer controlled RTTY station! We have certainly come a long way from the days of polar relays and tube converters!

So here we are in 1977, the year of the microprocessor in RTTY; where to go now? Let's look back for a second and envision a typical advanced RTTY station of 1976. With a microprocessor you have the capability to send and receive Morse code (at any speed), send and receive RTTY in Baudot or ASCII (for OSCAR satellite work), look like a super FIFO/UART combination, perform as a stunt box, Selcal, regenerative repeater, digital autostart, diddle and antididdle device, automatic logging unit, RY generator, memory box for contests, callsign lookup and recorder, or any other digital device you can dream up and interface to your microcomputer.

OK, so what's left, you may ask. If you let me take the liberty of gazing into my crystal ball, here is what I see. First, I can see quite clearly the ever-increasing use of micros like the 4040, 8008, 8080, 6800, 6502, SC/MP, etc., in amateur designed circuits dedicated to RTTY. By mid-1977 the majority of RTTY amateurs should have some type of micro in use in their station, even if only to look at! Many of the micros will be used to provide intelligent terminals which can be used for text editing before transmission and for preparing data for storage on a tape cassette.

It is also reasonable to expect microprocessor controlled radio repeaters in 1977 for both RTTY and voice applications. These will be interfaced with A/D converters which could give time, temperature, weather reports, etc., when certain access codes are received by the computer. In addition, I foresee more sophisticated remote monitoring of repeater technical parameters, where voltages, temperature, and currents are transmitted in ASCII, when inquiry codes are received by the repeater. In the late 70's it is also likely that RTTY repeaters will be linked across the state, or country, thus allowing the computer amateur to converse with others thousands of miles away.

I also can see the increased use of magnetic tape for file storage of RTTY pictures and other information generated on the computer. Five level tape will become more and more scarce as cassette tape standards begin to dominate the scene.

Also, in 1978, "canned" software for your favorite computer routines will be readily available from your ham or computer dealer. RTTY computer repeaters will also be very popular and will feature computer software for circuit calculations, antenna bearings, QSL information, and other applications. As costs come down on floppy disks in late 1978, early 1979, more amateurs will be using them for DX contest record-keeping, QSL info, magazine indexes, and personnel accounting records.

In addition, with the widespread use of video disk and video terminals, more computer amateurs will be transmitting and receiving video messages and symbols. Image processing and computer graphics will be fully developed on the RTTY frequencies. Who knows, your computer may be talking to my computer by 1980 and all I will have to do is lick the stamp on the QSL! Who said we're not a push-button society?

As you can see, we have come a long way over the past 15 years and we still have a long way to go. The journey of the future will be just as exciting as the one we have recently finished. You can take part in the evolution to whatever extent you desire. I know I will be there building microcircuits, reporting them to you in future articles and enjoying every minute of it.

So come on! If you missed the last 15 years, it's still not too late; you can start now on the next 15 years and maybe you'll be the one to write the next evolution of RTTY article in 1991. ■

WASTED PAGES

Obviously you are still experiencing some negative feedback regarding the involvement of *73 Magazine* in the subject of computers. I would like to comment. I submit that you have not yet presented the computer in such a way as to attract the greatest number of your readers. This is assuming that you have readers from age 14 through 65 years, and that they do not all have strong technical backgrounds. Or it may be that to many, although employed in some field of electronics, it's not necessarily digital electronics. (Many linear cats find the conversion to a digital world to be a painful process.) It should be clear that if an article on computers is written at a level for computer engineers, then for hundreds of ham subscribers who are oriented differently, that material represents 4 or 5 wasted pages in their magazine. Therefore, I propose that you seek and publish articles telling us why we should all be interested in the subject of computers. We should be told exactly what a computer will do for us. We should be told why it is necessary to "program" a computer, with simple elementary examples of "storage," "retrieval," and "processing." This should be written in simple definitive English, avoiding the use of professional programmer's terminology.

Let us move ahead on the subject of computers in *73 Magazine*, but starting at the appropriate point. Leave the advanced material to such publications as *Byte, Kilobaud, Megabyte*, etc.

I would like to emphasize that the foregoing does not apply to your many other fine articles involving digital techniques. These I regard as excellent for hams. I have just completed my own functional frequency counter built by me using information from at least 5 or 6 different articles published in *73*.

Harry D. Minshew W6ZOW
Hemet CA

Sorry, Harry, But Kilobaud *won't have that advanced material you mentioned any more than the I/O section of* 73 *will. I understand, and can relate to, your remark about how difficult it is to make the conversion from the "squiggly lines" to the world of "1s and 0s." Keeping this in mind, I am constantly trying to get material for the I/O section for beginners. On the other hand, there are a number of hams who have been in this for awhile and would like to see some good applications material. My job is very simple . . .just make everyone happy (hi). — John Craig.*

THE PRICING GAME

I just received the Holiday 1976 issue of *73*. After my first scan through (I generally make several passes), I noticed an ever-increasing trend by manufacturers to eliminate the price of equipment from their advertising. Why do they do this? It is difficult to compare similar products by different manufacturers if the reader has no idea if the price range is the same. How can the prospective buyer know which rig is best suited for his individual situation?

For example . . . Kenwood has a number of full page ads, back cover, 2, 67, 70. No prices on any piece of equipment. Ditto KLM's full page inside front cover. Same goes for Icom . . . 5, 42, 43, 55. How about Hy-Gain on page 7 and Ten-Tec on page 30? Even my friends at Klaus Radio on page 133 refrain from price quotations. Why all this secrecy? Are manufacturers afraid they will scare off prospective customers?

It is my belief that if suggested prices were once again part of the ad, a better comparison could be made by the reader. Also, I feel that some prospects are turned away because they "think" a piece of gear is more expensive than it actually is.

I would like to see price of equipment on each and every piece of gear that is advertised to the ham market. This does not mean that the prices would have to be firm. Everybody knows that individual dealers can make their own deal within the limits of sound business practice, so why not give the consumer a few guidelines?

Generally speaking, a dealer in amateur equipment will sell more than one product line. For example, a given jobber will sell both Kenwood and Icom. If he can vary from the suggested list price on Kenwood, he can do the same on Icom. The buyer can decide which rig he wants, assuming they both cost the same, judging strictly by product performance. Assuming there is a vast difference in price, he can decide whether the additional features are worth the additional cost.

A couple of years ago I sold my 1971 Vega. I put a "For Sale" sign on it along with the price and parked it in my driveway. Anybody who called already knew how much I was asking for the car. What they wanted to know was the particulars of the car itself.

About the same time, my friend sold his car. He failed to put the price on the "For Sale" sign. He got a lot of calls, but the first question was always "how much?" The answer was usually "too much." In this case, not listing the price turned away prospective buyers.

If all the ads in *73* had prices listed, I, for one, would be relieved of all kinds of doubt. That's all I have to say.

Streamwood IL

THE BYTE DEBACLE

Just read your December editorial: Someone doesn't like any part of computers, they want to keep *73* purely ham radio oriented. Fine, but there is at least one other side.

Wayne, I got the call W6ESV in 1948 and hammed to beat the devil for a few years; then gradually it pooped out. But doggone it, this computer technology has brought me out of the woodwork.

For the first time in years, I am excited about electronics again; my dream of a coat pocket portable QRP rig will get some more attention, but mostly I am plunging into the computer part right now. In the next few weeks, I'll be getting a simple system and putting it on the air as my subscription service computer, but that's only the excuse. I really want to get in there and have a lot of fun with that rascal whenever we are not running labels.

But you should know that it was *73* which was responsible for this change in me and *Byte* before that. I had liked that magazine, but the change in staff slipped by me until the editorial treatment got too far away from what I've come to think of as Green style. I discovered then that you were filling the gap which had begun to exist for me with the I/O pages of *73*, so I switched. Your hints in the editorial say there is something less than a perfect relationship between you and *Byte*.

What happened? Was it a property settlement as a result of divorce, did someone beat you out of it . . . what happened? If divorce, there are probably one or two of us out here who've been through it so you can use the word out loud and not shock us. If otherwise, get some code words together; we who read you a lot will read through. Point is, lots of people

I/O REPORT

by John Craig

On November 14, 1976, a friend of mine and I loaded my station wagon up with all of the "junk" we've accumulated over the last few years and headed off to the local swap meet. That evening we returned with 95% of all the "junk" we've accumulated over the last few years. The problem, which we suffered through all that day, was simply that the people who came to that swap meet didn't appreciate all the fine electronic and computer goodies we had to offer. In a rare stroke of brilliance, I came up with a solution. Why not hold a swap meet just for electronic enthusiasts, hams, and computer hobbyists? So I did. And it was neat!

Now, most hams are familiar with the "problem" I mentioned (regarding conventional swap meets), and that's why they save their stuff to sell at hamfests. But I think I may have come up with some ideas for turning people on to computers and ham radio, also. At first I was thinking small and started off by asking the members of our local computer club (during a meeting) if they would be interested in having a swap meet. Every hand in the room went up. Then I thought of all the other clubs in the area, the stores, the hams, and the electronic experimenters. If you're going to do something like this, it doesn't take that much more effort to do it right! So . . . I simply ran off some flyers on the ol' mimeograph machine and proceeded to mail them out to all the stores (computer stores, ham radio dealers, Lafayette, Radio Shack, etc.) and clubs. One of the most significant things I did to spread the word was tell some of my ham friends about it. Two meters was really jumping with the word! The swap meet was held on December 11, 1976.

I had three objectives in putting together *The First Annual Central California Electronic/Computer Hobbyists Swap Meet.* Number one, I wanted to sell all of that "junk" I mentioned earlier (only now, I needed to sell it to pay for the expense of putting on the shindig, and the $2.50 seller's fee didn't help much). Number two, I wanted to get a lot of people with common interests together for a good time. What a success that was! Number three, I had hoped to get some newcomers turned on to computers. I arranged to have several computers up and running with the idea of attracting the attention, and interest, of those who had never seen a home system before. Although we did manage to snare two or three newcomers . . . I didn't view that particular aspect of the operation as a major success. And I've got some ideas on how to improve it.

News? We need input, and one of the best sources is the club newsletter. Got one? We reiterate our longstanding offer of a free subscription to 73 *or* Kilobaud *in exchange for a spot on your ham or computer club newsletter mailing list. Deal?*

First of all, I think something like this should be put on by a ham radio or computer club (instead of an individual). Notices about the clubs and when they meet should be displayed at the swap meet, too. It could be a good fund-raising project if, for example, everyone donated a certain percentage of their proceeds to the club. But I really think one of the most important objectives should be to try to introduce personal computers to as many people as possible. It's going to be necessary to make sure the laymen of the community hear about your affair and are attracted to it, but it's going to be just as important to make sure that some worthwhile demonstrations are set up.

In retrospect, I feel I should have set one whole area of the room aside for personal systems demonstrations (instead, I had two or three demo systems scattered around). These systems need to be doing *something* besides playing games. Now don't get me wrong (I have plenty of games on my home system . . . and we all enjoy them very much). I think games are fine as far as getting someone's attention in a situation like this goes, but if that's *all* they see, you can hardly blame them for walking away shaking their heads and wondering why anyone would shell out over a thousand bucks for a "game player." No — more is needed. Some educational programs should be up and running . . . demonstrations of how the computer works in a home security system . . . ham radio demonstrations . . . recipe file and modification programs . . . home accounting . . . etc. And, a real biggee would be to have some small business programs going . . . or at least some small routines which would demonstrate what the computer could do *if* the software were finished. Just having the computer print out statements for use in billing is quite impressive (especially when you tell people that the response time and willingness to pay is substantially increased when computer-generated invoices are sent out — customers don't want to get a bad rating "in the computer system").

The prime objective of this whole thing is to hold a computer/ham/electronics swap meet. Therefore, you're going to be trying to attract people with those interests (which won't be hard) and they will be the easiest to get interested in computers and ham radio. But why not try to get others to come out and see what personal computer systems and hamming are all about? Spreading the word through as many civic organizations (Lions, Rotary, etc.) as possible, along with classified ads, should go a long way in accomplishing the objective.

Along with having a computerized ham station, why not have another station (without a computer) set up and handling traffic (perhaps another local station could be generating dummy messages to eliminate inactive periods)? My gosh! Think of it! There would be CBers to convert, too! There aren't many ways I'd rather spend a Saturday than hanging around with a bunch of people who are as enthusiastic as I am about personal computers. Everyone really had a good time, and the general consensus was that it should definitely be a quarterly or semi-annual affair. Therefore, I think we'll do it again in May. (It was also suggested that more than two weeks notice might bring in more people and not having it so close to Christmas might loosen up the pocketbooks some.)

THE FIRST WEST COAST COMPUTER FAIRE

Last month I mentioned the possibilities for making an impact at this convention with amateur radio applications . . . and this month we're going to take a look at some of the other areas the convention will be covering:

1) *Personal Computers for Education.* Kind of mind-boggling when you consider the immense area that topic covers . . . from every grade school in the country up through junior high, high school, and college (and of course, let's not forget the home). Every school in the country could afford to have computers for teaching now. And, it would be just great if they would get rid of the ridiculous red tape that makes it so hard to get them!

2) *Computers and Systems for Very Small Businesses.* I'm going to be giving a talk in this area, and as you may have guessed from previous I/O Reports, it's one of my favorite subjects.

3) *Program and Data Input via Optical Scanning of Bar Coded Information.* Sounds like something some magazine should get behind and support. They might even run a series of articles on how it works and how programs can be read directly into the computer from the magazine page. Hmmm . . . an interesting idea. I'll have to look into that. (In all seriousness, I think it's a fascinating idea, and I'm looking forward to seeing how it develops. There are other interesting — and super inexpensive — methods of getting data into our home systems . . . and I'm looking forward to their development, also. Would you believe using the home phonograph and a 33-1/3 LP record which has your library of games, applications programs, language processors, and anything else prerecorded on it?)

MISCELLANEOUS

At a recent meeting of our local computer club, the president took a survey of the members to see who was subscribing to which of the various hobby computer magazines. At the conclusion, someone asked, "Hey, what about *73?*" (It was on the list . . . he just hadn't asked about it.) Well, folks, I'm happy to report that *73* polled the highest of them all!

How to Use Those Old Teletypes

-- computer operation with a 60 mA machine

Several months ago I purchased an 8080-4BD microcomputer kit from The Digital Group and described my efforts in assembling and testing the unit in *73 Magazine*. During the period of getting acquainted with the Tiny BASIC Extended program that is supplied by The Digital Group Software Systems, I determined that what I needed was some way to make a hard copy of those programs I had so laboriously keyed into the machine's memory. Being able to store them on a cassette tape was fine, but what I needed was a method of writing them out on paper so that I could look them over and find the bugs and note changes. I also wanted a means of making a hard copy of the Biorhythm program output that is available in cassette form from The Digital Group Software Systems. The original tape just displayed only 14 days on the TV readout. I wanted to make a hard copy of the graph plot and run it for any length of time selected by the operator.

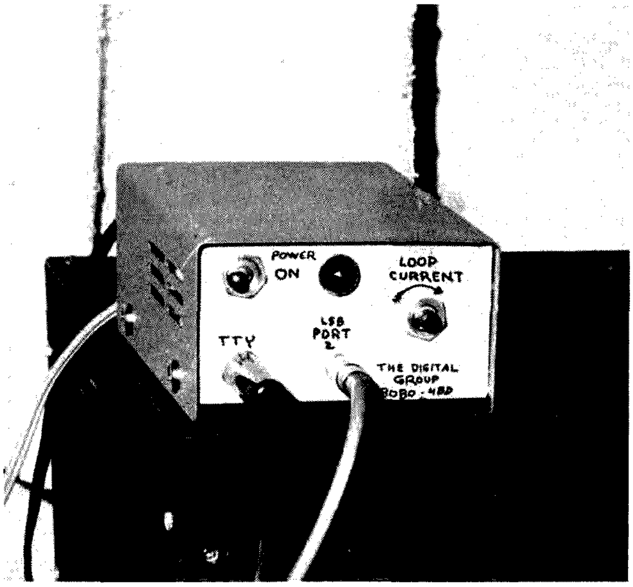
After several lengthy phone calls to Dr. Suding of The Digital Group, a new cassette program was released that is called Biorhythm Baudot. This program permits the operator to run the Biorhythm plot both on the TV screen and on a TTY machine, providing it is properly interfaced to the computer. The program also provides the operator with a capability of printing out programs that have been written in Tiny BASIC Extended. The results of some of the games that are available to The Digital Group equipment users may also be printed out on the TTY machine. The following article is a description of the interface unit I built to use with my 8080-4BD microcomputer, and how I use it to print out listings of my programs and Biorhythm charts.

Circuit Description

The circuit as shown in Fig. 1 consists of a loop power supply and a transistor driver circuit to permit the computer to drive a TTY machine. This unit is designed to stand alone and does not require any external dc loop supply for the TTY machine. The loop current adjust control is adjusted for a loop current of about 60 mA. I have found it will key the machine with as low as 30 mA without errors. The TTL logic signal from output port #2 LSB feeds a high voltage switching transistor, which in turn keys the TTY loop supply and keys the magnets on the machine. The IN-4005 across the output of the transistor is to keep transient spikes from causing troubles in the circuit.

Construction

The unit shown in the photographs is built in a



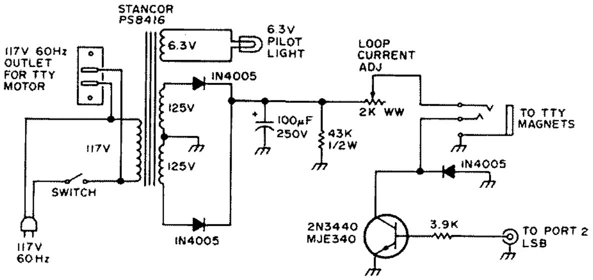


Fig. 1. TTY interface unit: The Digital Group 8080-4BD to Model 15/28.

Radio Shack equipment cabinet #270-252. It is 4" wide by 2-3/8" high by 6" deep. The outlet connector for the TTY motor power is mounted on the back of the cabinet chassis, along with the power cord fitting. The transformer is bolted to the back flange of the chassis. The filter capacitor is strap-mounted to the bottom of the chassis. The front panel is fitted with the power switch, loop circuit jack, port #2 LSB connector, pilot light, and loop current adjustment control.

Operation

The unit installed with the equipment is shown in the overall photo view of the microcomputer system at K7YZZ. It is seen sitting on top of the left-hand side of the computer unit, just above the computer power outlets. A twisted pair shielded cable is run from the TTY output connector to the selector magnets of my Model 28 KSR. The power cable from the Model 28 KSR is plugged into the rear of the interface unit. A single conductor shielded cable is run from the output port #2 LSB to the jack on the front of the unit.

To put the unit into operation, the microcomputer system is initialized with the Biorhythm Baudot cassette tape recording and the power on the interface unit is then turned on. The TTY machine motor is turned on and, if a run of Biorhythm is desired, the operator keys in 6 on the keyboard and then keys in RUN. The TTY machine will then begin to print out the Biorhythm instructions. The TV screen will also print out the same information at the same speed as the TTY machine. It should be noted that the system is set for a 60 speed machine. If the operator desires a listing of more than 14 days, the statement at 073 must be changed to give the desired number of days to run. For example, it would read 073 LET P = 60. This would make the TTY machine print out 60 days' worth of Biorhythm data.

If the operator desires to use the loading as a TTY readout of a program, then he should hit the RESET button and key in 6. Typing in the word NEW will erase the Biorhythm data from the memory but will leave the Baudot output undisturbed. Now the operator may key in or cassette load any program in Tiny BASIC Extended format. When finished, a listing of that program may be obtained on the TTY machine by typing in LST, and keying the RETURN button on the keyboard. This will cause the system to begin typing out a listing of the program entered into the memory from the keyboard or cassette. I usually set my TTY machine on double space during a listing run. This provides sufficient space between each line to make corrections to the program.

In attempting to play some of the games that are available from The Digital Group Software Systems, I have found that if the program's listing includes any TAB (0) statements, they must be deleted before they are run on the TTY machine. A TAB (0) statement makes the TTY machine print 16 lines of blank spaces and wastes time and paper. It is used in the computer mode to clean the TV screen and works fine there, but it is too slow on TTY.

Conclusion

This little unit works very nicely with the 8080-4BD system, and has been most useful in getting a good copy of the program listings for bug shooting. My friends have also really appreciated the fine Biorhythm runs I have made on the TTY machine. ■

Drive More Safely with a Mobile Dialer

-- hold 4 or 8 phone numbers in a PROM

William J. Hosking W7JSW
8626 E. Clarendon
Scottsdale AZ 85251

Shortly after arriving in the Phoenix area, I acquired the means (a Ma Bell pad) to use our autopatch. Shortly thereafter, having narrowly missed a little old lady while I was attempting to make a call on the patch and drive at the same time, I decided that an automatic dialer for commonly used numbers would be handy.

I had surplus 512 bit TTL PROMs on hand which seemed perfectly suited for the job. I started the design job about a year ago and, within a couple of weeks, had everything up to the actual tone generator working satisfactorily. At that time there were only about two options available for tone generation: one was a hybrid chip selling for close to $30 and another was the 566 PLL function generators. For size and economy reasons I chose the 566 route. After several weeks of less than spectacular success attempting to switch the 566s with TTL logic and maintain tone frequencies, I shelved the project and subsequently forgot about it. Motorola introduced a touch-tone generator in their CMOS line, the MC14410, which shows great promise. The tone switching can be CMOS, TTL, or just plain switches, and the output is approximately a sine wave. As soon as I got my hands on one of the chips, I pulled my automatic dialer off the shelf, ripped the 566s out, and wired in the 14410. It worked perfectly the first time.

Memory Arrangement

Since I had the 512 bit memories available, I had plenty of room to use a simple code. The basic memory is organized as 64 bytes, each eight bits long. I stored each digit of a telephone number in a byte location as

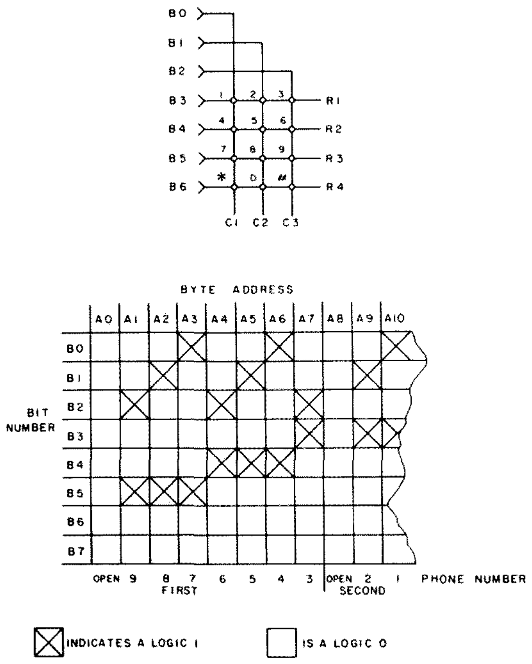

Fig. 1. Programming and coding for the four number dialer. Also shown is a sample program for the phone number 987-6543.

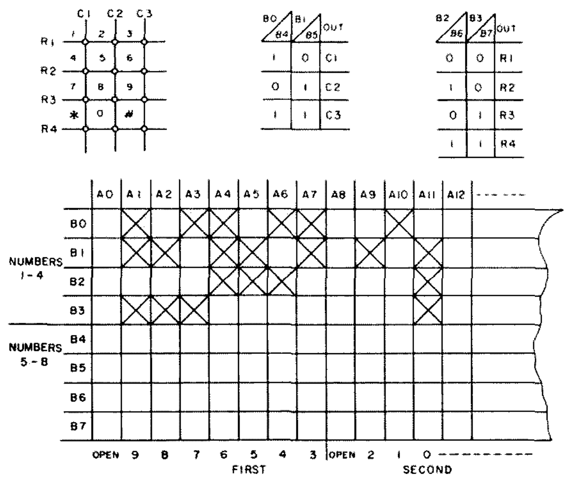

Fig. 2. Programming and coding for the eight number dialer. Also shown is a sample program for the phone number 987-6543.

a combination of a row and a column bit. An example of the coding is shown in Fig. 1. Each phone number requires seven digits (seven bytes) and, since the memory breaks down conveniently into address groups of eight bytes, that is the way I programmed it. This approach allowed eight phone numbers to be stored in a 512 bit memory and be selected with a BCD code.

A perusal of the surplus ads shows that 512 bit PROMs are not readily available but 256 bit ones are — and they are reasonably priced (around $5). The drawback, of course, is that a memory of half the size can only store half as many numbers (four). In order to store more telephone numbers in a smaller memory, a more complex coding system is necessary.

A scheme I developed later to achieve the higher density coding is shown in Fig. 2. Using this coding, a phone number would be stored in the first four bits of seven bytes and another phone number in the last four bits of the same seven bytes. A data selector chip selects which four bits out of each byte are to be used. With this scheme the first four telephone numbers are stored in bits B0-B3 of words 0 through 31 and the second four stored in bits B4-B7 of the same bytes.

Circuits

Circuits for the four number and eight number units are shown in Figs. 3 and 4 respectively. Everything up to the output of the memory is the same for both units.

A 7400 gate is cross-connected as a start/stop flip-flop. When the start button is pushed, it sets the F-F, which starts the 555 clock generator. The clock generator feeds a 7493 counter and a 74121 monostable through an inverter. The counter counts the clock pulses and puts out a binary address to the memory. For each clock pulse, the monostable puts out a pulse which gates the selected tones on for a short period. The inverter after the clock causes the gating to start with address position A1 instead of A0. This allows time for your transmitter and the repeater receiver to be fully on before the first tone comes along. The outputs of the counter are decoded with a 7411 gate whose output stops the start/stop F-F when a count of seven is reached. The two remaining memory address inputs are selected by a BCD coded switch.

For the four number model the memory outputs go through NAND gates to the tone generator. The monostable strobes the NAND gates, letting the selected row and column information through.

For the eight number model, the memory outputs feed a 74157 data selector which selects outputs B0-B3 or B4-B7, depending on the select input from the BCD switch. In this version the data strobing is done with the 74157 instead of with the NAND gates. The NAND gates and an added 7404 hex inverter are now used to

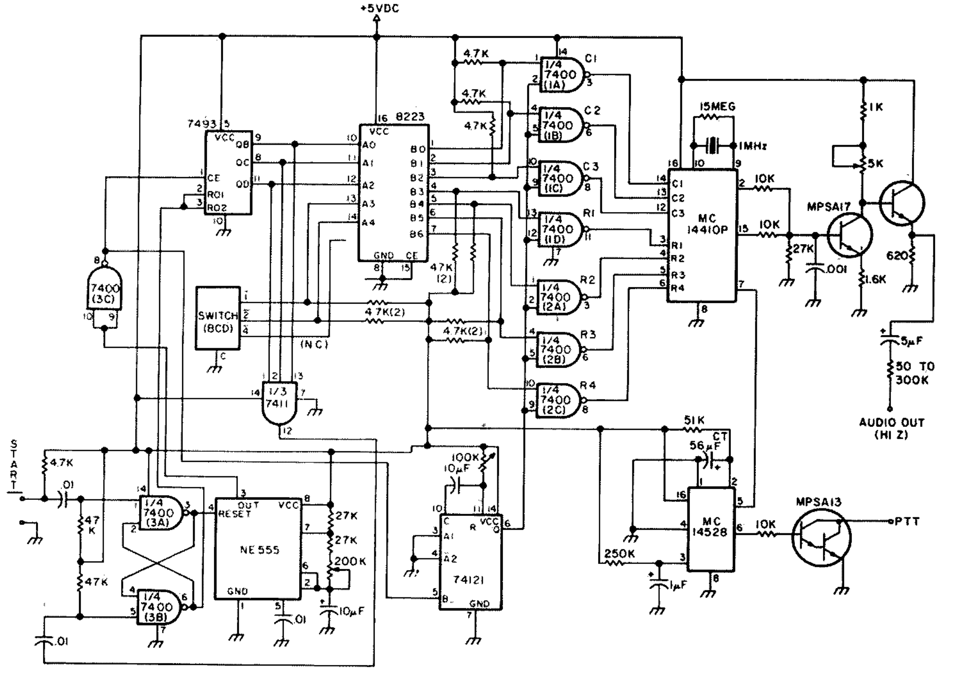

Fig. 3. Schematic diagram of the four number automatic dialer.

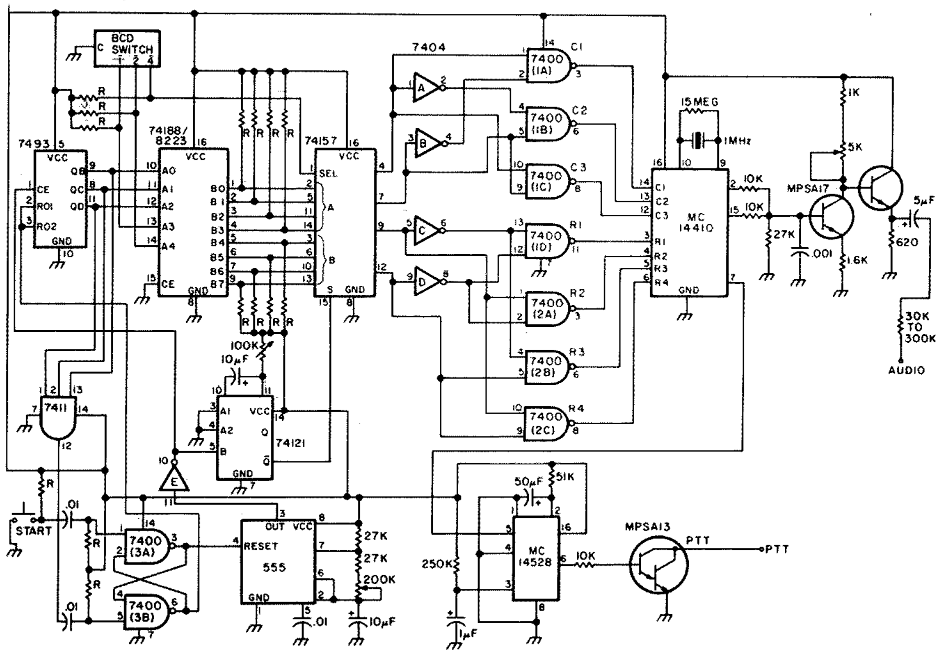

Fig. 4. Schematic diagram of the eight number automatic dialer.

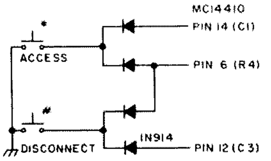
Fig. 5. Schematic of the added switches for access/disconnect.



decode the 74157 outputs to give proper row and column inputs to the tone generator.

In both cases the NAND gate outputs put a logic low on the appropriate row and column inputs of the MC14410 to produce the desired tones. The output of the tone generator is filtered and buffered, and a level control provided. My schematics show a high value of series resistor, since most of my radios have a high impedance input.

Pin 7 of the 14410 is a pulsed logic output which is used to trigger a 14528 monostable which, through a Darlington transistor, operates the transmitter PTT line. The delay on the PTT line with the parts shown is about one second. Capacitor C_T can be varied to change the hold time.

In both Figs. 3 and 4 the BCD switch is shown wired for complemented outputs. This means that a switch is open when selected rather than closed when selected. If a complement output is not available, the 4.7k resistors must be changed to 470Ω and connected to ground instead of +5. Also, the common then connects to +5 instead of ground.

All of the above takes care of the actual phone number once the patch is accessed, but in our case it takes a " * " to access and a " # " to disconnect the autopatch. To do this I added two pushbuttons and 4 diodes to directly turn on the proper row and column tones. The connections I made for this purpose are shown in Fig. 5. Not shown is an LM309K 5 volt regulator I use to provide the five volts from the 12 volt line.

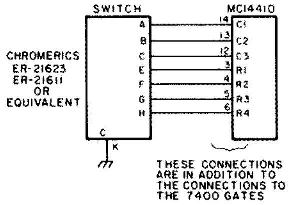
Operation

Operation is simple. I used a BCD coded thumbwheel switch for the number selection. I select the number, push the access button and, when I get the dial tone, push the start button.

Conclusion

The circuit works perfectly as is and the current drain isn't excessive. It seems a shame to use CMOS devices (14410, 14528) with the power hungry TTL devices, but one must use what is in the junk box. I expect I'll build one using CMOS soon, although a memory might be a problem. A friend suggested a RAM instead of the PROM, since the field PROMs, once programmed, contain the same information forever. Although the RAM would allow reprogramming, it would also require a continuous power supply, however small, to maintain memory. Anyway, it's something to consider.

Fig. 6. Connections for adding a touch switch such as the Chromerics ER-21623 or ER-21611 to the dialer.



To make the unit more versatile, a switch such as the Chromerics ER-21623 or ER-21611 could be wired in the way I did with the access/disconnect pushbuttons, to allow the unit to function as a normal touchtone pad. The connection is shown in Fig. 6. If this is done, the switches of Fig. 5 are not needed.

I didn't include programming information on the PROM, as it is fairly readily available. However, I'll be glad to help anyone having trouble finding information (SASE please, though). ■

CONTESTS

Editor:
Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

ARRL DX COMPETITION

Phone
Starts: 0001 GMT Saturday, February 5
Ends: 2359 GMT Sunday, February 6
Starts: 0001 GMT Saturday, March 5
Ends: 2359 GMT Sunday, March 6
CW
Starts: 0001 GMT Saturday, February 19
Ends: 2359 GMT Sunday, February 20
Starts: 0001 GMT Saturday, March 19
Ends: 2359 GMT Sunday, March 20

These rules were taken from last year's contest. Please check the December issue of *QST* for complete rules and any last minute changes.

Briefly, the rules are as follows: All fixed station amateurs, worldwide, are invited to participate. All amateurs in the 48 states and Canada will try to work as many stations in other parts of the world as possible. All other stations will work only W/VE stations. Entries may be in either the CW or phone section; each is scored independently. Entries are further classified as single or multiple operator stations. Single transmitter multi-operator stations will be recognized as a distinct category from multi-transmitter, multi-operator stations. Two transmitters on the band at the same time are prohibited. Single operator stations may enter in either the all band, high band, or low band categories. High band is 20, 15 and 10 meters, while low band is 160, 80 and 40 meters. Operating on a band not allowed in your class is permitted but those points will not be counted toward your total score. Crossband and crossmode contacts are not allowed.

EXCHANGE:

W/VE stations will send RS(T) and state or province. All others send RS(T) and power. KH6 and KL7 are considered DX.

SCORING:

Score 3 points for each completed QSO. Each station may be worked once on each band on each mode for contact and multiplier credit. Final score is the total number of QSO points times the total number of countries on each band (for W/VE stations), or the total number of continental states plus VE/VO licensing areas worked on each band (for DX).

AWARDS:

A plaque will be awarded to the highest single operator DX phone and CW station (non-W/VE) in each continent. On both phone and CW, a certificate will be awarded to the highest scoring station in each category and classification in KL7, KH6, each ARRL section, and each country where a valid entry is received. Also, a certificate will be awarded to each non-country winner DX entrant making 1000 or more QSOs on either mode. ARRL-affiliated clubs may also participate in club competition as described in *QST*.

LOGS:

A summary sheet, log sheets, and DX check-off sheet for each band used is required from all W/VE entries. DX entries must submit log sheets and a summary sheet. Separate logs, summaries, and check sheets are required for each mode used from all entries (no check sheets for DX). Logs and forms are available from ARRL, 225 Main St., Newington CT 06111.

CALENDAR

Jan 22 - 23	CD Party — Phone
Feb 5 - 6	ARRL DX Contest — Phone
Feb 5 - 13	ARRL Novice Roundup
Feb 11 - 13	QCWA QSO Party
Feb 12 - 13	10-10 Net Winter QSO Party
Feb 19 - 20	ARRL DX Contest — CW
Feb 19 - 20	YLRL YL-OM Contest — Phone
Mar 5 - 6	ARRL DX Contest — Phone
Mar 5 - 6	YLRL YL-OM Contest — CW
Mar 13	South Dakota State QSO Party
Mar 19 - 20	ARRL DX Contest — CW
Mar 26 - 27	CQ Worldwide WPX SSB Contest
Mar 26 - 28	BARTG Spring RTTY Contest
Apr 12 - 13	YLRL DX-YL to Stateside YL Contest — CW
Apr 16 - 17	CD Party — CW
Apr 23 - 24	CD Party — Phone
Apr 26 - 27	YLRL DX-YL to Stateside YL Contest — Phone
June 11 - 12	ARRL VHF QSO Party
June 18 - 19	WVA QSO Party
June 25 - 26	ARRL Field Day
July 2 - 3	QRP Summer Contest
July 4	ARRL Straight Key Night
July 9 - 10	Bicentennial Celebration Plus One (ARRL)

Included are a few late-comers from overseas and the official dates for ARRL contests.

ARRL NOVICE ROUNDUP

Starts: 0001 GMT Saturday, February 5
Ends: 2359 GMT Sunday, February 13

The contest is open to all amateurs in any ARRL section. Operating time must not exceed 30 hours total during the 9 day period while off periods may not be less than 15 minutes at a time. Times on and off must be entered in your log. Crossband contacts are not allowed. Novices may work anyone while non-Novices must work Novices only. Each station may be worked only once regardless of band.

EXCHANGE:

RST and ARRL section.

SCORING:

Each completed QSO counts one point. The total multiplier is the number of ARRL sections and foreign countries worked. VE8 counts as a separate section. The final score is the number of QSO points plus your ARRL code proficiency credit (15 wpm = 15 pts.) times the total multiplier.

AWARDS:

Certificates will be awarded to the highest scoring Novice in each ARRL section. Multi-operator or higher class licensees are not eligible for awards, but the top ten scores will be listed in the results.

LOGS:

Use official ARRL forms available from: ARRL, 225 Main St., Newington CT 06111. All entries should be sent to this same address.

Please check the January issue of QST *for any last minute changes in rules or operating times.*

QCWA QSO PARTY

Starts: 2300 GMT Friday, February 11
Ends: 2300 GMT Sunday, February 13

Every contact with another QCWA member will count; contest is only open to members. Briefly the rules are as follows.

EXCHANGE:

QSO number, QTH (state, province, or country), name, and QCWA membership number.

SCORING:

Each contact with another QCWA member counts 1 point. Any foreign QCWA member except Canada, Mexico, and US possessions count 5 points per QCWA QSO outside their own country. Count a multiplier of 1 for each state, province, US possession, country, or political sub-division designated by a callsign prefix. Final score is QSO points times multiplier as usual. A contact with the QCWA memorial station W2MM/6 counts for 2 points. Each station may be worked only once regardless of band or mode.

FREQUENCIES:

Phone — 1805-1825, 3940-3960, 7240-7260, 14240-14260, 14280-14300, 21340-21360, 28640-28660.
CW — 1805-1825, 3540-3560, 7040-7060, 14040-14060, 21040-21060, 28040-28060.

Contacts made on net frequencies are not valid!

LOGS:

Identify each sheet with name, call, QCWA number, address, city, state, and zip. Number pages and staple them together. Logs should show all exchange info plus band, mode, time, date, and duplicate check columns at right. Compute score and include with logs. Logs must be mailed not later than February 20th to: Ralph Cabanillas, Jr. W6IL, 2359 Creston Dr., Hollywood CA 90068.

TEN-TEN NET WINTER QSO PARTY

Starts: 0000 GMT Saturday, February 12
Ends: 2400 GMT Sunday, February 13

The contest is sponsored by the Ten-Ten International Net of Southern California, Inc., and is open to all amateurs — but only 10-10 members are eligible for awards. All contacts must be made on 10 meters, any mode, and a station may be counted only once.

EXCHANGE:

Name, QTH, and 10-10 number.

SCORING:

1 point for each contact plus 1 point if with a 10-10 member. Maximum of 2 points for any one contact.

LOGS:

Logs should include date and time of each contact as well as the required exchange information.

AWARDS (for 10-10 members only):

Certificates to first and second place winners in each US district, Alaska, Hawaii; each VE district; Central America and Caribbean; South America; Europe; Africa and South Atlantic; Asia and Northern Pacific; Australia, New Zealand and South Pacific. Send logs to Grace Dunlap K5MRU, Box 445, La Feria TX 78559, by March 31. For complete results, see the *10-10 Net Summer Bulletin*. To become a 10-10 member, work any 10 members and send a list of those contacted along with $3.00 to the manager in your district.

YL-OM CONTEST

Phone
Starts: 1800 GMT Saturday, February 19
Ends: 1800 GMT Sunday, February 20
CW
Starts: 1800 GMT Saturday, March 5
Ends: 1800 GMT Sunday, March 6

Sponsored by the YLRL, the contest is open to all licensed operators throughout the world. All bands may be used but crossband operation and net contacts are not permitted. Phone and CW contacts will be scored as separate contests, so please submit separate logs. A station may be contacted no more than once in each contest for credit.

EXCHANGE:

QSO number, RS(T), and ARRL section or country.

SCORING:

One point is earned for each station worked, YL to OM or OM to YL. Multiply the number of different ARRL sections and/or countries worked. Contestants running 150 Watts input or less on CW and 300 Watts PEP or less on phone may multiply the score by 1.25 (low power mult).

LOGS:

Entries in your logs must show band worked at time of contact, time and date, and transmitting power. Please remember to submit separate logs for phone and CW. Send logs to: YLRL Vice President, Beth Newlin WA7FFG, 826 W. Prince Road – 06, Tucson AZ 85705.

A cup will be awarded to the first place YL and OM on both phone and CW. Second and third place winners in each contest will receive certificates. Certificates will also be awarded to the high score phone and CW winners of each state, VE call area, and each country.

CW COUNTY HUNTERS NET AWARDS PROGRAM (net meets Mon 2400Z/3575, Wed 2300Z/7055, Sat 1400Z & 2000Z/14070 and Sun 1430Z/7055)

Basic awards are $1.00 with endorsements for band, mode or mixed. Seals and endorsements free at time of issue; thereafter SASE, list and award number required. No date limits, all confirmed contacts count – mobile, portable or fixed. Honor system – no signers needed but awards manager reserves right to request any one or all QSLs at applicant's expense. Send list of required info to: Awards Manager, George Levensalor W1DPJ, 399 Buck St., Bangor ME 04401.

THE UNITED STATES OF AMERICA COUNTIES AWARD BY CALL AREAS

12 separate awards for confirmed contacts with stations operating in counties of the 12 US call areas, 1 through 0, Alaska and Hawaii. Classes: A = all counties in call area; B = 2/3 counties; C = 1/3 counties. Anyone holding all 12 awards Class A (all counties in US) issued free trophy!

Talk About DX-- WOW!

-- you just never know

Twenty meters seemed unusually quiet after listening to locals and heavy static crashes on eighty for an hour, but it was late and the middle of the week. When I had changed bands and flipped the antenna coax switch under the desk, it sounded as though propagation had been cancelled for the evening. The swr checked out at a normal 1.2 to 1.0 so I assumed the antenna was still up and connected. CQ brought no reply, and a careful headphone search across the band for another diehard was fruitless. Inactivity was at a peak.

Patience and a hundred Watts into a vertical verge on fantasy when you need a kilowatt and a four element quad, but with freaky conditions you just never know, so I persisted. Nothing. A few hours before I had been fascinated by the fine quality of the pictures from the Viking on Mars – a low power TV transmitter 250 million miles away. Irony. Finally I parked the transceiver on 14.225, set the Scanalyzer sweep width on 50 kHz and idly sorted through the QSL file, musing on yesteryear's hard-won souvenirs of youth, all-night vigils, forty Watts and a good Zepp.

Just as I was thinking about shutting down I heard a clear "Hello, hello." Precisely on frequency, nice audio. Nothing on the scope, and the S meter didn't move, but I recalled fiddling with it earlier in the evening when eighty was so noisy. And on a quiet band the Yaesu was notably kind to the most minute signals.

"Hello, hello" again, then silence. "W7IDF, near Seattle," I said hopefully. "Name's Ken. You're very weak but perfectly readable."

The reply was prompt. "Thank you. I could use a little help here. Are you busy?"

"Okay. You are the only signal I've heard on the band in the last half hour. Good quality, just weak, and I didn't get your call."

"Thanks. This is AC25OLS. Alpha Centauri Twenty Five Outer Limit Survey. If you don't mind, I'd like to ask you a few questions."

"That's a fascinating call, old man. Been watching a lot of 'Star Trek' re-runs lately?"

"You lost me there, but never mind. This is a routine solar systems check and we appreciate your cooperation. By the way, you're only the third response I've had from this planet; the first two were W6s and initially helpful with information about your society structures, but after a bit they indicated definite hostility. Something to do with the ARRL Countries List. Now then, I'll just run down this form and we'll fill in a few blanks. Okay?"

"Listen, if you guys are having a party over there, that's fine, and good luck, but why don't you just let the rig cool off and play a little poker? Or spin-the-bottle if it's YL night. This ain't old-timey CB, good buddy."

"Please, I'm allowed only eight hours scanning and two hours after entering synchronous orbit here, so, if you don't mind . . ."

"Great. I suppose you're going to tell me next that you learned English at U.C.R.A. What are you guys really up to?"

"Language is irrelevant, obsolete for aeons. We're communicating by the standard process of heterodyning brain waves. It's simple but obviously you wouldn't understand. No offense. Now, how about some answers?"

"Okay, I'm game. Up to a point. AC25OLS from W7IDF, and if anyone wants to break in I'd be grateful. Go ahead."

"Well, the main assignment: Is there intelligent life on your planet? What I got from those W6s pretty much confirmed my suspicions."

"Don't jump to conclusions; California's another world, and your contacts probably were in L.A. to boot. Did they leave you a little confused?"

"I mentioned that we had opened a file on your recent upper atmosphere nuclear explosions and asked if they could give me any explanation. What they told me was depressing – this business of you guys killing each other in wholesale quantities every generation, and killing other life forms for fun. You got off on the wrong foot some-

where. And all that stuff about racial antagonism, fortified political fencing all over the planet, parochial language structures perversely blocking communication – weird, man! Any comments?"

"About intelligent life on Earth? I used to think there was, but by the time I got into long pants I was very doubtful. Haven't seen much evidence of intelligence lately, but I may have missed something."

"I see. Let's try to get something specific here, so who would you say is the wisest man on the scene today?"

"Hope nobody is taping this. Well, you asked a tough one, and I really don't know what to say. Woody Allen, I suppose. I would have said Stan Freberg a few years ago – and I didn't know how to spell his name then either – but he's kept a pretty low profile since that business of painting airliners to look like locomotives."

"I don't get it."

"Some PR assignment from Western Airlines I think. They wanted a scheme to make people think their planes were as safe and reliable as trains. That was before Amtrak."

"I think we're getting off on the wrong track here. Another item – we've noticed some miscellaneous junk orbiting Mars, and now you've got a primitive sensor device set up on the surface there. How about that?"

"Alfa Charlie Two Five Oscar Lima Sierra from W7IDF. This is going to look great in the log, Al. About the Mars lander, I cannot tell a lie; we done it. I think it was timed to celebrate two hundred solar orbits under our own flag, without a failure. Going around, I mean."

"Curiouser and curiouser. Your planet already has about 560 million orbits in the records at the main office, so what's so great about two hundred? Never mind, I'll just put down 'responsibility accepted' and you probably won't hear anymore about it. But off the record, what was the real reason?"

"Beats me. We have a lot of problems right here we can't seem to solve. I heard some rumor about dumping our nuclear waste products on uninhabited planets, but who knows? Just curiosity I suppose."

"Whaddya mean, who knows? You said it was your lander."

"Well, our technologies are symbiotic and accelerating. The result is we're already up to our trifocals in astonishing inventions, horrifying weapons and new taxes. Those pictures from Mars are great, but I don't know where we're going really, or why. Guess that's what I mean. I'm dumb; go ask a scientist."

"Sounds worse than I thought, but cheer up – you guys are new at the game. A recent check at this station reported no activity at all, just random life forms too elementary to allow communication. Let's see now – a simple question about your interplanetary probes: How are they powered?"

"Chemicals. Hydrogen and oxygen for the rockets, maybe, and to produce them I suppose some nuclear plant output is involved, but most production is still based on fossil fuels. And some hydroelectric wattage – courtesy of gravity. But the big money's in fossil fuels."

"Figures. The same old natural resource rip-off, but don't get discouraged – you'll soon be into solar energy. Anyway, no sweat for the galaxy. Certainly you haven't broken the speed-of-light barrier yet."

"Doubt it. Maybe on the freeways now and then. Why don't you check with Caltech or somebody? Like I said, Al, it's moving so fast us peasants don't know up from sideways anymore. Hey fellas, any breakers?"

"Don't apologize if science isn't your bag. As a matter of fact, all the significant data are being collected and banked automatically; it's just nice for me to have a contact now and then. Sometimes this job gets on my nerves. Oh yes, one bad thing about all these sensors: They're totally insensitive to motivation phenomena. With immature social systems that tend to go off in kinky directions, it can get hairy for our prognosis processor, so tell me what's behind the emphasis on life-destructive devices. Why all the fancy weaponry?"

"AC25OLS and anyone else who would please join us, from W7IDF. I don't think that was a very nice thing you said there, Al, about immature social systems. But to answer the question: I really don't have the faintest idea. In my lifetime there have been four major wars, and yet I've been all over this planet and rarely met anyone I didn't like. Also, don't get the idea that we're not law-abiding folks – just take your clothes off publicly and unless you're getting paid to do it, I guarantee you'll find yourself in the pokey before you can say Buck Rogers. About the ICBMs and red telephones, I'd level with you, but I'm as much in the dark as you are."

"See what I meant about you guys being a little weird? Sounds like science fiction and makes less sense. Well, time's running out but thanks for the chat. I'd like to stick around but I have to get to the next solar system. You know how it is, 'promises to keep, and miles to go before I sleep.' Bet that surprises you."

"Not really, Al. Nothing surprises me much anymore, and also I noticed that when I thought I was switching to the twenty meter antenna, what I did was put the rig on the dummy load. Anyway, it's long past midnight, so have a nice day." ■

An Automatic BC Squelch

-- another use for your 2m squelch

Hubert E. Minchow
1065 Lynnwood Avenue N.E.
Renton WA 98055

If you have ever wished you could listen to your car's commercial broadcast receiver without missing a call on your transceiver or scrambling to twist volume controls when a ham signal pops in, the QRM Zapper is the answer to your problem. The QRM Zapper will silence the broadcast receiver whenever your transceiver picks up a signal and then restore the broadcast receiver a few seconds after the transmission ceases. The Zapper also silences the car radio while you transmit, so you can enjoy a QSO without being QRMed by the news.

While the original Zapper was designed to be used with an Icom IC-22A, any transceiver is capable of furnishing the two trigger signals required to make the Zapper work. The triggers have to be negative going, so the transmit trigger is obtained from the microphone switch by connecting to the hot (ungrounded) side of the switch. In the Icom IC-22A, the receive trigger is taken from the emitter of Q26. Q26 drives the receive signal lamp when an incoming carrier breaks the squelch, so the emitter voltage drops to near ground potential and satisfactorily serves as the source for the receive trigger.

For transceivers without the carrier lamp feature, the receive trigger can be picked up from some point in the squelch or AGC circuits where the voltage swings from near 5 V or higher to ground potential with an incoming signal. If necessary, a simple transistor switch can be added to invert a voltage from one of these sources and amplify its swing to meet the requirements for the receive trigger.

The QRM Zapper is designed around a 555 integrated circuit, and it silences the broadcast receiver by switching off the battery voltage to the broadcast receiver. Either trigger from the transceiver starts the action of the timer. Triggering the 555 removes the car battery source from the broadcast radio. The battery is reconnected a few seconds after the end of the trigger signal. A new trigger applied while the 555 is timing out stops the rundown of the timer, cancels the elapsed rundown time and causes the battery to remain disconnected, so QSOs free of QRM from the broadcast receiver are enjoyed by electronic means rather than manual adjustments.

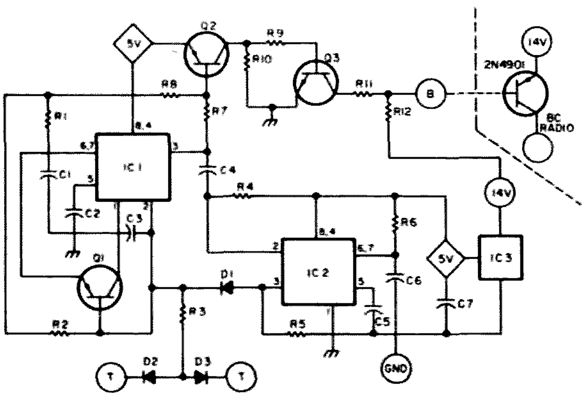

Fig. 1. Schematic of the QRM Zapper.

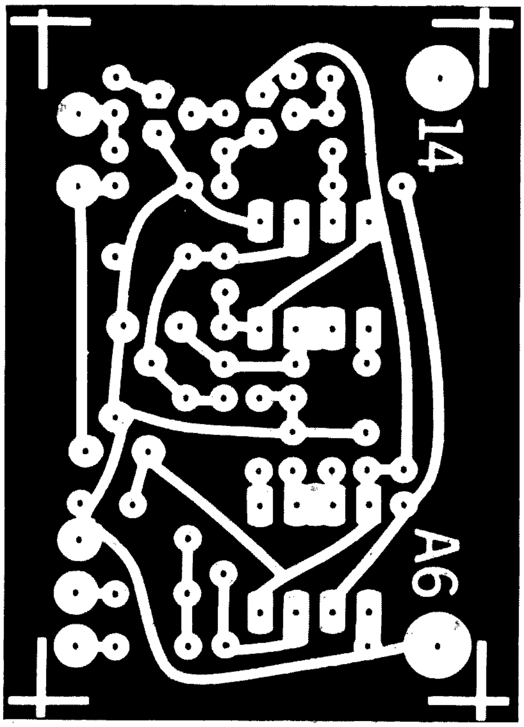
The 555 timer is operated in the missing pulse detector circuit shown in the 555 data sheets (refer to Fig. 1). Q1, a small PNP transistor, prevents the RC timing circuit R1-C1 from charging until the trigger applied to the base of Q1 is removed. This forces the 555 timer IC1 to begin its timing action after the carrier ends or the microphone switch is released; it delays the connection of the car battery to the broadcast radio for the few seconds necessary for the RC circuit to charge. The beginning of the negative going trigger at pin 2 of IC1 causes the output pin 3 to go high and remain in this state until the RC timing circuit has charged to a certain level. The output at pin 3 of IC1 controls a 2N4901 transistor switch which is in series with the broadcast radio battery source. When pin 3 is high, the switch is open. When pin 3 is in the low state, the switch is closed and the broadcast radio is on. Therefore the Zapper silences the broadcast radio for the duration of the trigger signal plus the time it takes to charge the RC timing circuit.

The trigger signals connect to the cathodes of the two 1N4001 trigger diodes, D2 and D3. The diodes isolate the transceiver circuits from the Zapper and from each other while coupling the trigger signals to the trigger pin of IC1 and the base of Q1. IC2, a 555 in a monostable circuit, is triggered by the end of the output pulse of IC1. IC2 generates a 0.1 second holdoff voltage in the trigger circuit immediately following the timed period. The holdoff voltage prevents any switching disturbance in the broadcast radio battery circuit from retriggering IC1.

Originally the Zapper was operated with the car battery voltage on the ICs, but IC1



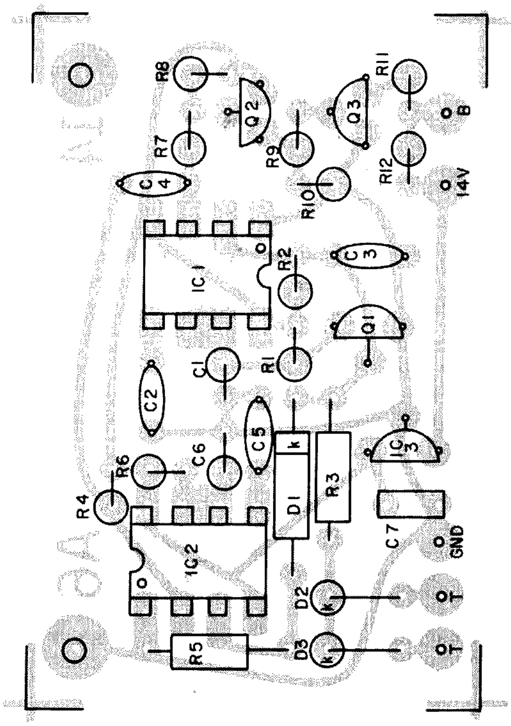


Fig. 2. Component layout of QRM Zapper printed circuit board.

would intermittently self-trigger the broadcast radio and sometimes silence it continuously. Several brands of 555s were tested but they all performed the same. The solution was to operate the 555s at 5 V. IC3, a 78L05 miniature voltage regulator, supplies the 5 V. A pair of small transistors, Q2 and Q3, are used to interface between the 5 V output of IC1 and the 14 V level of the 2N4901 switch. The 2N4901 transistor is used instead of a relay and is capable of handling 5 Amps.

The three ICs and the three small transistors with their circuit components are mounted on a small printed circuit board. The single sided board measures 1.2" x 1.9". The 2N4901 transistor and heat sink are mounted separately. A Wakefield 6103 heat sink was used, but any small heat sink for T0-3 style transistors can be substituted since there is very little heat developed by the 2N4901 transistor.

One wire runs between the PC board and the 2N4901 transistor, connecting the solder pad marked "B" on the PC board to the base terminal of the transistor. The emitter of the 2N4901 connects to the car battery positive source, and the collector is wired to the broadcast radio positive battery lead. This places the transistor switch in series with the car battery and the broadcast receiver.

The QRM Zapper can be assembled in its own box or preferably installed inside the broadcast receiver case. The small size of the printed circuit board should make it easy to find mounting room inside the radio cabinet. The 2N4901 transistor on its heat sink can be installed inside or outside the radio by drilling a pair of mounting bolt holes through one of the vertical sides of the heat sink. Number 4 machine screws are large enough to hold the transistor. The metal transistor case is the collector connection, so the 2N4901 has to be insulated from the heat sink with a mica insulator.

Before installing the printed circuit board inside the radio case, remove the wire(s) connected to the cold side of the broadcast radio's on-off switch and connect the wires that were removed to the collector of the 2N4901. This places the radio load in the switched output of the Zapper. Then solder two wires to the vacated lug of the on-off switch and connect one of these wires to the emitter of the 2N4901. Solder the other wire to the pad marked "14 V" on the printed circuit board. These wiring changes enable the broadcast radio on-off switch to also control the power to the QRM Zapper.

Two wires for the triggers are installed from the transceiver to the solder pads marked "T" on the printed circuit board. The Icom IC-22A has an accessory socket at the rear which was used for the trigger wiring so the transceiver could be disconnected and removed from the vehicle. If a socket

Parts List

C1, C6	4.7 uF, 20 V tantalum capacitor
C2, C3, C4, C5	0.02 uF, 50 V ceramic capacitor
C7	20 uF, 6 V tantalum capacitor
D1, D2, D3	1N4001 diode
IC1, IC2	555 IC
IC3	78L05 voltage regulator
Q1, Q2	3638A PNP transistor
Q3	2N3904 NPN transistor
R1	2.2 megohm, ¼ W resistor
R2, R4, R9	22 k Ohm, ¼ W resistor
R3	1 k Ohm, ¼ W resistor
R5	4.7 k Ohm, ¼ W resistor
R6	120 k Ohm, ¼ W resistor
R7	2.2 k Ohm, ¼ W resistor
R8, R12	560 Ohm, ¼ W resistor
R10	820 Ohm, ¼ W resistor
R11	100 Ohm, ¼ W resistor

The QRM Zapper board 14A6 etched and drilled is available from the CRS Company, P.O. Box 1125, Kent WA 98031 for $3.00. Completely assembled and tested boards are $10.00 from the same supplier.

Additional parts required: 2N4901 transistor, T0-3 socket, Wakefield 6103 heat sink, mica insulator, hardware, box and wire.

is not available on your rig, it would be wise to provide some practical way of disconnecting the trigger wires, such as installing a plug and socket or mounting a screw type terminal board at the transceiver.

The QRM Zapper can also be installed in its own case. A small box similar to an LMB number 00Z which measures 2-5/16" x 2-1/8" x 1-3/4" or a Radio Shack #270-235 box of slightly larger dimensions will easily contain the printed circuit board and the 2N4901 with its heat sink. If the broadcast radio has an in-line fuse holder, a Radio Shack #270-1281 in-line fuse holder can be used to connect the Zapper in series with the broadcast radio battery source. Connect the fuse holder leads to the 2N4901 transistor socket in such a manner that when the fuse holders are mated, the car battery is connected to the emitter and the broadcast radio lead connects to the collector of the transistor. Then connect a wire from the 2N4901 emitter to the 14 V solder pad on the printed circuit board. Connect the ground solder pad on the printed circuit board to the vehicle ground system.

All components, including the three ICs and the three small transistors, are soldered directly to the printed circuit board. Component locations are shown in Fig. 2. Most of the diodes and resistors are installed vertically, with one end of the body placed against the PC board and the other lead bent back along the body and inserted into its solder pad hole. The printed circuit board can be mounted with two #2 machine screws in the upper corners. Holes for this purpose are indicated in the foil pattern and shown in Fig. 2. The foil side of the board must be separated from any adjacent metal by at least 0.2" by the mounting hardware to avoid shorting out the Zapper. ■

LETTERS

from page 86

out here are maybe confused as to how come you ain't at *Byte*. If anyone asks, they are concerned, and if anyone is concerned, then maybe they have some feeling of bias for you; you won't lose anything by levelling.

Now, about *Kilobaud*: I think dividing off some of this really great I/O stuff from *73* and making two magazines is a mistake. In all fairness, I should say I've called the last five presidential elections wrong, excepting that I picked McGovern over Nixon. So much for batting averages. But here's my check for $12; you have and are doing a lot for ham radio and I sure want to see what is next out of the Wayne Green typewriter.

Hang in there; not many of us in the silent majority ever speak up, but we do write checks and buy magazines from newsstands and pull for the guys we *know* are wearing the white hats.

Arnold Senterfitt W6ESV
San Diego CA

If you're really interested, write Byte *about it . . . and I'll sure want to see what kind of an answer you get. I wonder how they can explain to readers what they did. — Wayne.*

THE LF-VLF CAPER

First I want to congratulate you on publishing such a fine magazine as *73*. The technical articles are written in first class style, and the advertising is well laid out and in good taste. The letter written by the fellow in Little Rock (the VLF caper) prompted me to comment on his discussion of the VLF frequencies. First of all, there is nothing secret or mysterious or "out of this world" about the LF or VLF frequencies. I have been doing solar flare propagation work at LF and VLF for about 5 years. Most of our studies are at 24 kHz and 27 kHz for the S.E.A. (Sudden Enchantment of Atmospherics) and at 18 kHz for S.E.S. (Sudden Enhancement of Signal). I have monitored and recorded every frequency between 15 kHz and 600 kHz with my RBA-7 equipment and have yet to hear recorded voice transmissions that speak no known earth language, or dogs barking at each other. What I do hear are military, commercial navigation, omega, and standard stations throughout the world. As far as the lack of design in VLF, the solar flare patrol division of the A.A.V.S.O. (The American Amateur Association of Variable Star Observers) has been using solid state receivers (home built) for years. We still rely on miniature miller coils, and have even designed an S.E.S. receiver for 18 kHz using a ceramic filter with an associated chart recorder interface. As for the lack of commercial gear available, I could list dozens of receivers that can tune "below the broadcast band," not to mention the Drake DSR-2 or the National HRO-500. If he really wants to know what the LF and VLF frequency spectrum is all about, he can purchase a copy of my book, *Propagation and Solar Flare Recording Handbook For The Ham, SWL, and Radio Astronomer*, which will be published in early spring by Tab Books. Again, keep up the good work.

Carl M. Chernan WA3UER
Tarentum PA

WRAPPERS

Having been an avid reader of your magazine for the past couple of years, I have not had need to write. I wait impatiently every month for each issue.

I wish to state unequivocally that I disapprove your dropping the brown wrappers that PROTECT the magazine. If they cost extra, please send me a bill. My latest copy arrived with the corner torn off on the bottom, and with bent corners on both the top and bottom that go through the whole magazine. This may seem picky, but my three year old back issues are all in better condition than my new magazine.

I also am complaining about the mailing label being pasted on the front, along with a postal sticker defacing the cover.

I hope sincerely that you print this, as I would like all those who agree that the practice of not protecting the magazine should stop, to send Mr. Green a letter.

Thank you for letting me get on the soapbox; I really hope you change your policy.

John P. Steiner
Worthington MN

Sorry OM, but a printer's strike forced the Holiday issue to be mailed without wrappers. Things will soon be back to normal; sorry again for the inconvenience. — Ed.

THREE MORE YEARS

The Holiday issue of *73* is great! I just got it yesterday and got an idea for my car's two meter antenna.

The article on the "Frumious Hexadecimal" is interesting but incomplete. I've been programming on IBM equipment for a living for about three years now, and in our shop, hex numbers come in many sizes: X, H (this one the author knows), F, and D. These are all indicative of the amount of storage taken up by the hex number. X indicates a single byte, a value from X'00' to X'FF' (0 to 255). H is a half word, or two bytes, and the numbers go from H'0000' to H'FFFF' or 0 to 65,535. F is for a full word, four bytes long, and D is a double word, eight bytes long. I have never seen anyone use just the quote marks to indicate that a number is hex, but it's an interesting idea.

In the same article, the author misses one of the neater properties of hex numbers. He takes the number H'39BD' and laboriously converts it to 14,781 decimal, then remarks how difficult the conversion into binary would be. Translating from decimal to binary is no picnic, but hex to binary is a natural. Simply take each hex digit and write it as a four digit binary number (to match hex 0 through hex F). Here, 3 becomes 0011, 9 becomes 1001, B is 1011, and D is 1101 for a translation from H'39BD' to B'0011100110111101' in less time then it takes to write this. (The B stands for binary.)

Also in this issue, I find someone willing to charge $4 for a deck of 25 cards in FORTRAN. Surely anyone with half an ounce of typing skill (even myself!) and access to a keypunch could punch these up in ten minutes or less. Let's see now, my installation figures that each card costs it 1.7¢, call it 2¢ with the "labor" involved. Prices may vary, but I see a 400-800% profit on each sale. How do you reconcile this exorbitant fee for such a simple function? Heck, I'll do it myself for half price. Send check or money order to Joe Larson, 1983 Strongs Avenue, Stevens Point WI 54481. Do I hear a dollar? Hang around a university computer center and you can probably do it even cheaper.

Now, if that $4.00 included the computer run of 15,000 pages or so, it would probably be well worth it.

Aside from all this, keep up the good work, Wayne. I've enjoyed *73* as long as I've been a ham, since 1964. Put me down for three more years.

Joe Larson WA9NDV
Stevens Point WI

TO FCC — NUTS!

Chairman of the FCC
York Street
Gettysburg PA

Dear Sir,

I am extremely interested and disturbed about the amount of time the Commission takes to process all amateur radio licenses. I have been licensed since 1961 1961 and I can understand, with the increased num-

Continued on page 126

Briefs

from page 17

minute period would eliminate the problem of false alarms caused by test transmissions and accidental activation of the ELTs.) Postlethwaite told *73* that a major aircraft company has agreed to make all of their used tube radios available to repeater sites throughout the nation.

Once the ELT signal is detected, a low cost direction-finding unit designed by Postlethwaite is used to pinpoint the location. As a plus, this DF unit can be used by repeater groups to locate illegal transmitters and jammers. Watch future issues of *73* for articles on the Happy Flyers and a construction article on the DF unit, which can be built for under $50.

The Happy Flyers are seeking members and attempting to form groups throughout the country. At present, there are no squadrons east of Oklahoma. Anyone who is interested in their proposals is welcome to join, with no requirements of being either a ham or a pilot. There are no dues or membership fees. For further information, write to *Hartley Postlethwaite WB6CQW, Electronic Search Education and Coordination, 1811 Hillman Ave., Belmont CA 94002.*

An "administrative delay" at the FCC in Washington has resulted in a two to three month holdup in the implementation of multiple choice code comprehension exams at regional FCC offices. Two high-placed spokesmen confirmed reports of a delay in the process of putting the duplication of new exam tapes out for bid.

At press time, the FCC estimated all offices will have the exams by the beginning of March. They will consist of a five minute "typical" QSO. After the copy is sent, applicants will be given a ten question multiple choice exam. The passing grade is 80%.

In September, a Denver resident visiting Colorado Springs and the Pikes Peak area drove to the 12,500' level of the auto highway on the Peak to do some hiking. Heavy clouds obscured the mountain and, in hiking, he stumbled and fell to a ledge located on the upper portion of the Bottomless Pit drop-off — a sheer cliff of 1300 feet. Unable to move, the hiker lay for 2½ days with a compound fracture of the leg, frostbite, and in shock, without food. Water he obtained by soaking a handkerchief in snow, and then squeezing it out.

The victim was rescued by the El Paso and Arapahoe Counties Search and Rescue Teams in cooperation with the US Army Medical Helicopter teams from Fort Carson CO, after being found by two members of the Pikes Peak Radio Amateur Association. The amateurs were members of the S&R Team and, with other area amateurs, had been in on the "manhunt" since it began. Communications were provided by the PPRAA repeaters on 16/76 and 37/97 (highest amateur repeater in the world) and by the Telestar 87/27 repeater.

It required three rock climbing rescue teams to lower themselves by ropes 1000' to the stricken man, after which a further descent of 800' was necessary in order to permit a helicopter to transport the patient to the hospital. Lake Erie ARA *Newsletter*, Lakewood OH.

Conflicting reports abound on how the new 40 channel CB rigs are doing in FCC tests. *Electronic Engineering Times* reported most of the units submitted had failed to pass the new emission standards tests. But *Communications Retailing*, reporting on a CB symposium held during October in New York, quoted FCC Engineer Ed Schafer as saying better than 50% of the units submitted for test were meeting cabinet radiation specifications. At the FCC labs outside Washington, spokesman Frank Caperidge told *73* the tests show about 53% failing and 47% passing. Caperidge says there are six tests, with the cabinet radiation test a major stumbling block. Local oscillator radiation is measured with a field strength meter at 3 meters, and Caperidge says most of the 40 channel units that are failing can't meet the 5 mV specification. The FCC lab, at press time, was working overtime on the 500 units submitted for inspection, with 106 certified, and less than a month to go.

Northglenn CO has banned amateur radio towers. According to the Pueblo Ham Club Bulletin *Grid Leak*, an appeal is underway, after a lower court judge upheld the ordinance. Twenty-five witnesses appeared against the law, but the city government called no one. Despite the testimony supporting amateur radio and the need for towers, Judge Clifford Goebbel found against the hams. The appeal is expected to take at least a year.

In April, 1779, a group of mutineers took over the HMS Bounty . . . sending the Bounty's captain William Bligh and 18 crew members loyal to him on a 3 thousand mile journey to Timor, and back to England. The descendants of those who stayed with the ship are still on Pitcairn Island, a South Pacific land mass of 2.5 square miles, off the main sea-lanes, with a very poor anchorage so boats are infrequent. The only reliable means of communication with the outside world is amateur radio, through VR6TC, which is operated by Tom Christian. The main generator recently blew up and burned leaving the 150 islanders with small auxiliary generators, and a real energy crisis. Bert Moser W6HS is running a fund drive to buy a new generator for Pitcairn, and you can help by sending a contribution. Bert's address is 2153 Lyans Drive, LaCanada CA 91011. Thanks to *Overmodulation*, Bulletin of the Poinsettia ARC, Ventura CA.

The Concord Brasspounders Club, New Hampshire's oldest, helped 15 Novices get their licenses this fall. The Brasspounders were the first club to use *73*'s new *Novice Class Study Guide* and Code Tapes as part of a program designed to gain FCC certification for the *73* materials. Club secretary Nate Sanderson WA1RWP reports quick responses from Gettysburg, several father-son and husband-wife teams, and more classes in the works. (It's efforts like these that are making New Hampshire contacts a lot easier to come by. — Ed.)

If you're lucky enough to find yourself in Hawaii this winter, check out the amateur radio news being transmitted Monday nights over the state repeater system. KH6GQW puts the news together, and transmits starting at 8 pm local time over 28/88 Diamond Head, 34/94 Haleakala, and 22/82 Mauna Loa. "And that's the way it is . . ."

The FCC has suspended *all* license fees, after a US Court of Appeals ruling which invalidated the Commission's fee schedules. In a suit brought by broadcasting interests, the court found that the FCC had to justify all of its fees based on the cost of any given service. An FCC spokesperson told *73* the Commission decided it had no alternative but to suspend the fees effective January 1st, and launch a study into the legal and administrative implications of refunding fees collected under the current schedule. Following a US Supreme Court decision in 1974, the Commission established a new set of fees, while at the same time requesting legislative action to correct deficiencies in the laws that enable it to collect them. The FCC position, at press time, was that without an act of Congress, it could not collect *any* fees. It could then be some time before ham or CB license applications will require the $4 fee. As for refunds, most of the pressure is coming from broadcasters, whose license fees run into the thousands of dollars. The FCC budget is not expected to suffer, since the fee money goes into the general fund, with a separate budget for staff salaries and operating expenses. The plaintiffs in the case included the National Association of Broadcasters, the National Cable TV Association, the Electronics Industry Association, and Capital Cities Communications.

Obtaining insurance coverage for mobile rigs is becoming an exercise in frustration in many areas of the country. With the proliferation of rip-off artists coming on the heels of the CB boom, many insurance companies are refusing to insure mobile radios, at any price.

Until recently, automobile radios were covered under comprehensive policies as another item in the car. However, in most areas of the country, this has changed. Many automobile insurance companies are including clauses which specifically exclude 2 way radios from coverage. Depending on where you live in the country, you might be able to add an endorsement to your policy to cover the rig. This is completely up to the state insurance commissions (if the companies wish to offer it). In New Hampshire, an extra five dollars covers 2 way radios completely. Down in Massachusetts, which has the highest rate of automobile theft in the country, coverage can't be bought at any price.

Most policy endorsements carry requirements that the rigs be securely fastened to the automobile. (Quick-release mounts are *not* considered secure mounting.) Another requirement is that the car be locked. What this means is that in order to have your claim paid, it's necessary that the car show signs of forcible entry. If the thief who ripped off the rig had a master key or even put a coat hanger through a gasket, chances are that nothing will be collected since no signs of forcible entry will be evident.

The best way to get around these requirements used to be the personal property floater policy, which insured just the radio as a piece of property. *73* talked with several insurance companies who no longer offer them for two way radios. They draw no distinction between CB rigs, business band radios, or amateur units. Spokesmen at the companies pointed out that from the thief's eye view, they all look the same, as many hams will attest to after having their rigs ripped off or hearing "breaker 19" on the local repeater.

It's expected that if radio theft and the CB boom continue at their present pace, virtually no insurance will be available within the next couple of years for 2 way rigs. In the meantime, the best precautions that hams can utilize are locking cars, engraving driver's license numbers on rigs, hiding antennas, or, best of all, removing the rigs completely from the car when leaving it for any period of time.

More than a half dozen petitions have recently gone into the FCC hopper, with two others bounced. A proposal to force SSTV out of the phone segments on 20 meters was dismissed, along with a request that AM be banned below 10 meters. Both actions are not interpreted to mean actual death of the proposals, but instead the FCC's judgment that they can be covered under existing dockets, probably 20777 (bandwidth).

Other pending petitions include RM-2767, which asks for multiple trusteeship of club stations; RM-2768, to allow concurrent holding of Novice and Technician class licenses; RM-2769, requesting formation of a

Tune Up a Random Wire

- - world's simplest antenna for 80-15

A problem encountered by most apartment-dwelling amateurs is that of radiating a good signal on all bands, without causing TVI, when facilities are available only for a wire antenna of random length. We have achieved this very successfully by adaptation of an antenna-tuning circuit previously used by VK6ZEH in commercial installations.

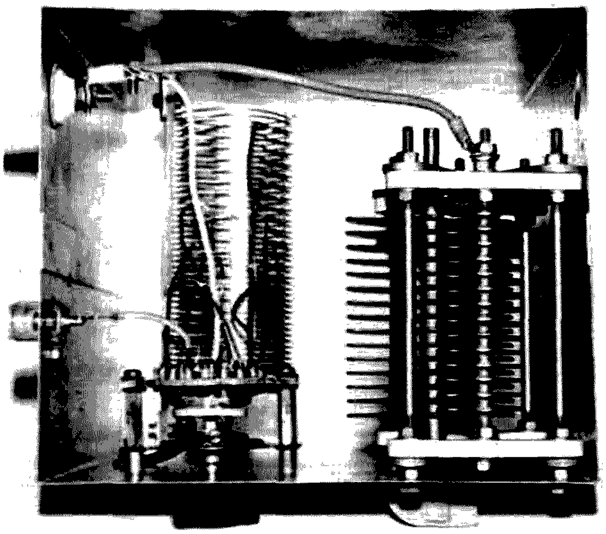
The necessary components were obtained as shown in Fig. 1 and the tuner assembled with the exception of the taps from the switches. A point worth mentioning here, in construction, is that the coil should be accessible to enable taps to be soldered on at any point around it.

It is essential that a good ground is available. Fortunately, at the 6DX apartment, the water system was all copper and its grounding properties good. Adjacent to the apartments was a filling station, with a very convenient tree at the back of the block. Permission was obtained from the flat owners, and, with the cooperation of the service station proprietor, 125 feet of wire became airborne at around 30 feet up. The length of wire is of no importance; anything more than 30 feet can be made to work on bands 80m to 15m. It is essential that the wire is placed in position and the end brought to the point where the tuner will be located. Any subsequent rearrangement will upset the system.

Reprinted from *Amateur Radio*, Journal of the Wireless Institute of Australia, October, 1974.



The photo clearly shows the construction and the heavy duty components used.

Tuning Procedure

The 80m band should be adjusted first. Place the capacitor in half mesh, the input tap about 10 turns up from the cold end, and the transceiver at midband. Feed a signal from a loosely coupled signal generator and run the top tap down the coil until a maximum S meter reading is obtained, then solder the tap in place. Now place an swr meter between the transceiver and tuner, using 50 Ohm coax. Apply low power from the transceiver and check for minimum swr. If it is necessary to move the capacitor considerably, re-center and adjust lower tap until the minimum swr is achieved. This can be done two ways: by switching off, moving, and rechecking, or by holding the lower tap with *well* insulated pliers and running up and down the lower section of the coil until the exact spot is found (WARNING – high voltages can be expected here; proceed with caution). Once the optimum position is found, by a very slight adjustment of the condenser, an swr of near 1.0 can be had from one end of the band to the other. If this cannot be achieved, select the lowest possible and readjust the top tap half a turn either way as necessary to lower the swr. When operating at the extreme end of the band, the swr should be no more than 1.2 and can be reduced by a slight adjustment of the capacitor.

The remaining bands are tuned in a similar manner. 28 MHz has not been included, as it is felt a suitable separate antenna can be erected and a separate tuner using smaller capacity and inductance constructed.

Features

One of the advantages of the tuner is that it can be adjusted to match any impedance offered by the long wire. It should be noted that in some instances, e.g., ours on 20m, the input tap is above the output tap due to the impedance being less than 50 Ohms.

No specific tap positions can be given as they are entirely dependent on the length, height and properties of the antenna. With a little

patience, the ultimate can be achieved, all your signal generated being radiated and not wasted heating up the antennas.

Good construction practices should be followed, using heavy duty switches and a variable capacitor. The wiring should be bare copper wire and firm enough not to sag. Plastic covered wire, if touching, and the wrong tap selected for tuning up, will result in fusion of the wires together. The whole assembly should be enclosed in a well bonded and *grounded* metal box. By leaving off the ground, the swr will rise to as much as 2.5 to 1.

The system can be used to match a vertical antenna in the same way. Tests to date have shown the system to work very well, and the comment of DX stations is often of surprise when they hear that the antenna is only a long wire. Working portable in the NW, Europe has been worked with ease using a 60 foot wire 12 feet up and a fair ration of DX using a 125 foot wire 30 feet up. Good DX! ■

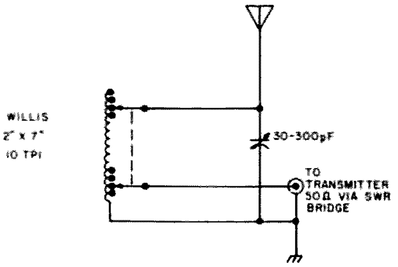


Fig. 1.

LETTERS

from page 116

ber of applications, how the time it takes can be multiplied. What I cannot understand is (since this process has been computerized) the time it takes to receive a license back from the Commission has not changed. In fact, it has increased!

When I got my Novice license in 1961, I waited six weeks from the time my test was mailed until my license came back. I am at present waiting for my Advanced class license (I was tested 10 Nov. 76) and I was informed by the examiner it would take about six weeks for my new license to come to me. This is the same amount of time it took to get my Novice back in 1961. HOW CAN THIS BE??

I would like to know how the routing and processing of the applications go when they leave the district office. Also I am interested in (since he has already proven himself by passing the exam and if he has a license), why can't the applicant be authorized to operate with the new privileges on a temporary basis until the new one has been issued?

There is no need to rush on a reply to this letter, because I will not be looking for an answer for the next six weeks.

Richard L. Swain

Here is a letter I sent to the FCC. The reason for doing the complaining should be rather obvious.

I am not trying to attack the entire FCC and say it is behind the times, because it is not. The fact is that the administrative section which does the actual processing and issuing of the licenses is GROSSLY inefficient and most likely is lacking in proper supervision.

I am a fourteen year veteran of the system (I am a member of the USAF), and I think I know how most government agencies work in their administrative sections.

I think the FCC could issue a temporary license at the field office or examination point for those who already have a license and callsign. Nothing makes most people madder than to order something pre-paid and have to wait two or three months for it to get to them.

I have discussed both subjects with several other amateurs and they agree all the way with me. What we would like to see is all others who have had the same problems voice their grievances or opinion on both.

Richard L. Swain K8AIT
Sawyer AFB MI

INSPIRATION

This is my first letter to any magazine, but the story on the five year old ham inspired me to write a few lines.

The first thing I might say is that my CB call is KET-5238, so this letter is not to cut down CB. It might step on a few toes in the ranks, but if the shoe fits, wear it.

It would seem that if a five year old can pass a Novice ham test, the people who want us to give up our standards as hams, by dropping the code and/or making the test simpler, should take another look.

I agree that we need new blood in the ham ranks, but we also must keep our standards high! If someone doubts this, they should look at other countries' licensing. Not every country has Novices for instance. So when a Novice goes to Germany, they do not license him at all. Can you or anyone else imagine a person with a "Communicator" license going to any country trying to get a license? It would probably be like going to another country with a CB license asking for an amateur license with General privileges.

PHOOEY!

I must say "phooey to hams" in reference to those who don't acknowledge uP byters. My subscription to *73* started soon after I found I/O. It's a shame that a few people can't see past their ham dials, and into a world of logical bits. But of course everyone to their own — and mine is uPs. However, keep up the good work in *73* on both sections and maybe a few byters might just cross over and hit the airways.

To the byters I must pass the bytes on — while flying Delta over Georgia, an interesting gentleman (from TI) introduced me to TI's TMS9900 16 bit uP having a 3 MHz cycle time. With 17 vectored interrupts, full 16 bit capability on both A & D bus lines. And no special memories or ICs for system interfacing are needed.

The data sheets I have sure look like the PACE, 8080, and 6800 uPs have got a bigger brother. The cost of the 9900 is more but you save with the I/O and interrupt interfacing, program development, and program execution time.

Oh! And a new bipolar memory SN54S400 (S400) 4096 bit static RAM having a 75 ns R/W cycle.

Wow! Sure looks like '77 is going to be "heaven, next stop."

Francis T. L. Dossey

WIMU

Many thanks for the prize subscription to your magazine you contributed to the WIMU Hamfest. I won it in a 2 meter hidden transmitter hunt.

As a former president of this hamfest (when I was a K7 from Wyoming), I realize the difficulty of getting support and prizes to put on an event such as this. It is sometimes difficult to put on a good get-together without the generous support of ham dealers and the magazines. I want to extend to you my personal thanks for the subscription and for your support of our hamfest.

The WIMU Hamfest is for the hams in Wyoming, Idaho, Montana, and Utah. It is the largest and oldest hamfest in these western states. This year's event at Mack's Inn, Idaho was the 44th year it was held. We broke an all-time attendance record this year with a registration total of about 365. Perhaps a hamfest of this size is not too big by eastern standards, but considering the sparse ham population of these states, and the distances involved, the attendance is pretty remarkable. Some hams travel over 800 miles every summer to come to the hamfest.

FEEDBACK

I enjoyed reading the two part article about commercial marine radiotelegraph operators in the Nov. and Dec. issues. However, before any *73* readers get the wanderlust and strike out for such a career, a couple points should be made. First, there are about four times more operators available than ships. The Radio Officers Union is tighter than a drum and chances of more bodies entering in and thinning out the ranks are very poor right now. Also, on page 160, Dec. issue, the Coast and Geodetic Survey is listed as a source of employment. C&GS was done away with in 1965. National Ocean Survey in Seattle may be helpful. Also, MSA is not correct — should be MSC, Military Sealift Command. One in SF is called MSCPAC. I don't know the address.

Cliff Appel WB6AWM

Novice Q&A

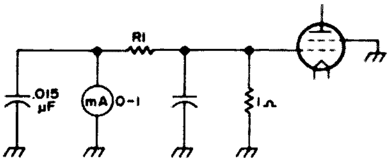
This column will be a monthly feature of 73 Magazine. It is hoped that it will be of assistance to beginners and old-timers alike. We only ask that your questions be kept as general as possible. We will try to answer all queries received. Please mail your questions to Technical Editor, 73 Magazine, Peterborough NH 03458.

Q. What is the correct procedure to use when measuring the grid current of a cathode-driven amplifier?

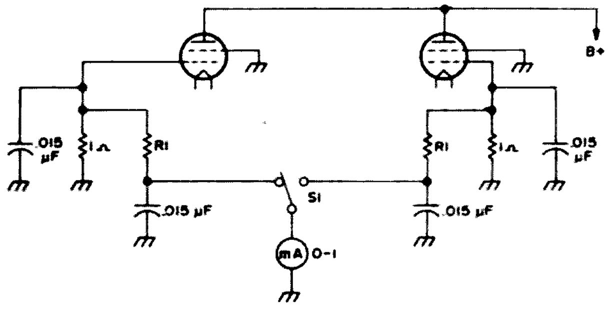
A. Measuring the grid current of a cathode-driven amplifier can be a delicate task, since it is a ticklish job to unground the grid sufficiently to permit a metering circuit to be used, yet still hold the grid at rf ground potential. The inherent inductance of most bypass capacitors permits the grid circuits to "float" above ground at some high frequency and, as a result, the amplifier exhibits instability and parasitics. This problem can be avoided with the metering circuit of the figure (A). The control grid is grounded with a 1Ω composition resistor, bypassed by a .015 pF disk capacitor. The voltage drop generated by the flow of grid current across the resistor can easily be measured by a millivoltmeter which is calibrated to read in terms of grid current. Individual grid current for each of a parallel pair of tubes may be measured by the circuit of (B) in the figure.

The internal resistance of the 0-1 dc milliammeter plus the series resistor E1 determines the maximum current in the order of 60 mA. This is very convenient, as the reading of the meter scale can easily be multiplied by 100 to obtain the actual value of current. When 100 mA flows through 1Ω, there exists a potential of 0.1 V across the resistor. The meter should read 0.1 V full scale to correspond to a grid current of 100 mA.

For example, with a Triplett #221-T (which has an internal resistance of 55Ω), the voltage drop across the meter itself is 0.55 V when 1 mA flows through it. To convert the milliammeter to a voltmeter reading 0.1 V full scale, a series multiplier must be added. A voltage drop of 0.1 V exists across a 100Ω resistor when one mA of current flows through it. The difference between 100Ω and 55Ω or 45Ω must therefore be added in series with the meter to convert it to read 0.1 V, full scale. On the other hand, placing the meter itself across the 1Ω resistor without the series multiplier will result in a full scale reading corresponding to 55 mA. Thus, if maximum grid current is below this latter figure, no series resistor is required for the meter. Conversely, high values of grid current produce greater voltage drop across the 1Ω resistor and larger values of series multiplier resistance are needed.



"A"



"B"

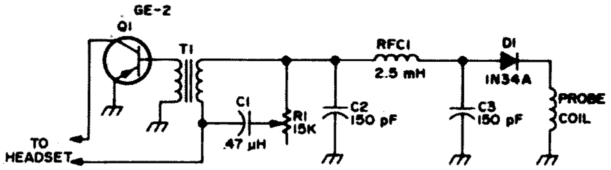
Q. What is a microwave radiometer and what does it do?

A. The microwave radiometer is a receiver of electromagnetic energy used to measure thermal radiation in the rf spectrum. Typical sensitivities of the order of 140 dBm are made possible by comparatively long post-detector integration time and provision for cancellation of receiver gain variation in the period of one observation.

These devices are mostly used in radio telescopes for measuring extraterrestrial radiation and for passively detecting and identifying military targets (both ground and airborne).

Q. Is there a very simple, one transistor circuit for a CW monitor?

A. Yes, see the figure. For the tone desired, adjust potentiometer R1. Place the pickup coil anywhere near or in the transmitter. If the gadget doesn't "take off" immediately, reverse the primary winding connections of the transformer, which, incidentally, is a Lafayette TR-110.



Q. When operating a transmitting set containing a fan, must all covers be closed?

A. This depends on the design of the ventilation system. Large transmitters containing two or more air blowers are designed for "closed cover" operation within the ventilation system. Removing the covers allows the air (in some cases) to flow helter-skelter without maximum effect. On ham transmitters, especially SSB units of short duty cycle, there is generally no problem.

Q. Is it unusual that the final tubes of a transmitter must be replaced every four months? If so, what should be checked?

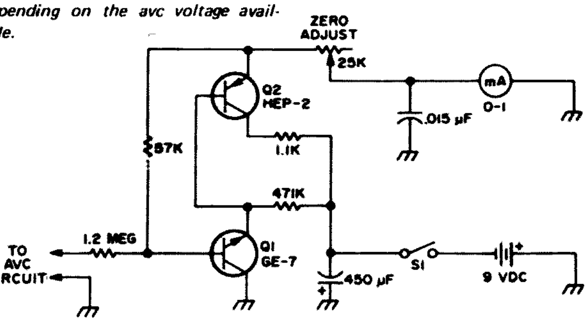
A. Yes, frequent tube replacement is unusual. First measure the bias to the final in accordance with the manual or a tube data sheet. Next measure the final plate voltage. If these do not check out (or are way off), then review your method of tuning. Running a transmitter into a poorly matched antenna, with its attendant high swr, does not help the final tube much. Overdriving the final tube is another way to shorten power tube life. Therefore, check the drive to the final, too.

Q. Is it possible to add a transistorized S-meter to an all-band Japanese-made receiver?

A. The circuit in the figure works well on most receivers and it is easy to connect. For O1, the following transistors may be used: GE-7, SK-3011, NR5, TR-10, DS75.

For Q2: HE-1, SK-3005, TR-06.

The value of the input resistor, shown as 1.2 MΩ in the schematic diagram, may have to be adjusted depending on the avc voltage available.



Q. What modifications should be considered when modernizing a receiver?

A. First, replace the rf amplifier with a high-gain tube like the 6BZ6 — a new socket may be needed. The rectifier (5Y3GT) can be eliminated with a silicon plug-in replacement. Stabilize the voltage on the bfo (6J5) with a separate VR tube or zener diode. Add a product detector.

Q. When used in SSB work, the detector is usually referred to as "product detector." What is the reason for this?

A. Because the detector has an output amplitude which is proportional to the mathematical product of the amplitudes of its two inputs, carrier and modulating signals.

Q. Is there any way to use 90Ω coax cable with a vertical antenna which requires a 50Ω match?

A. Cut two parallel pieces of the 90Ω coax cable. Make sure they are the same length. By paralleling them the result will be 45Ω or so.

Q. Can #18 shielded wire be used to connect a doublet?

A. No. First, the doublet's 72Ω impedance does not match that of the wire. Second, shielded wire is not the same as coaxial cable. Finally, capacitance per foot is much higher with shielded wire than with coax.

Furthermore, because the shield is not uniformly spaced over the wire, the capacitive distribution will be uneven.

Q. What is the difference between a direct probe and an isolation probe for a scope?

A. Just as the name implies, a direct probe is a test probe which is connected to a piece of shielded cable without series resistance or capacitance. The isolation probe can be either capacitive or resistive — or both — and serves to present a higher impedance, a lower capacitance or higher resistance (less load) to the circuit under test.

Q. What can be used in an emergency to check circuit continuity?

A. Use your receiver and two test leads — one connected to the receiver's antenna terminal and the other terminated directly to the antenna. You'll notice continuity — and varying degrees of such — by the resultant increase in receiver gain on the S-meter. Tune to a station that is fairly weak without the antenna connected.

AMSAT

QSL BUREAU

AMSAT maintains a QSL bureau for confirming satellite QSOs. Any US or VE member or satellite user can maintain a few cases on file and will receive cards confirming contacts with other satellite users. Any AMSAT member can also send out cards confirming satellite contacts by means of the AMSAT bureau. There is no cost for cards destined to W, K or VE stations, and a flat rate of 6¢ a card to all other countries.

I recently had a chance to peruse the dead cards (cards at the bureau for which the recipient has no envelope on file). There are DX cards, rare states and special event stations cards. Some people nearly have enough cards for an OSCAR or Satellite 1000 award waiting for them at the bureau. These cards will have to be returned to the senders or destroyed in the near future. If you use the satellites but do not have a case on file at the AMSAT QSL Bureau, send at least one in today. If you are an AMSAT member, you can also send out cards at the same time. You may be pleasantly surprised as to what you will find in your first returned case. The address is: AMSAT QSL Bureau, Dennis Grinerod WA1EHF, Manager, 564 Stillman St., Bridgeport CT 06608.

TWO SATELLITES IN ORBIT

We have marked the fourth anniversary of the launch of AMSAT-OSCAR 6 and the second anniversary of the launch of AMSAT-OSCAR 7. It is important that the lifetimes of the spacecraft not be foreshortened by the use of excessive uplink power. The QRP days have shown that modest amounts of rf can put good signals into the spacecraft. Less than 10 Watts of radiated power is all that it takes to put a strong signal into A-O-7 Mode B, and less than 100 Watts will do the same for Mode A on both spacecraft, provided that there are few QRO operators. Please, do not use or encourage high power operation via the satellites. If you have trouble hearing yourself, don't increase your uplink power, but examine your receiver. If you CANNOT hear the beacon signals from AMSAT-OSCAR 6 on an overhead pass, you need to improve your receiving capabilities.

TWO SATELLITES TO COME

AMSAT is currently building two spacecraft. The Phase III spacecraft has a launch date in December, 1979. The European Space Agency (ESA) has agreed to provide a place on the second ARIANE launch vehicle flight. This will be the first non-US launch of an OSCAR spacecraft. AMSAT is also working on a Phase II spacecraft. This spacecraft is known as A-O-D, and is destined for launch in late 1977. It is a joint venture of AMSAT, Project OSCAR and JAMSAT. It marks the first time that Project OSCAR and AMSAT have cooperated on building flight hardware. A-O-D will contain two transponders: a 145/29 MHz unit built by AMSAT in Washington DC, similar to the one flown on AMSAT-OSCAR 6, and a 145/435 MHz transponder being built by the Japanese AMSAT Association. A prototype of this transponder has been tested on Mount Fuji in Japan with promising results. One unique aspect of that transponder is that it uses a power FET in the final.

The frequencies to be used by A-O-D are as follows:

UPLINK (MHz)
145.85-145.95, 145.9-145.95
DOWNLINK (MHz)
29.4-29.5, 435.1-435.15
BEACON (MHz)
29.4, 435.095

Note that the 145/435 transponder bandwidth may be slightly narrower than shown and incorporates passband inversion (cf. A-O-7 Mode B).

This satellite is primarily designed for the educational program to provide the capability for satellite demonstrations and communication through to 1980 and the launch of the first Phase III spacecraft.

SPONSOR A SOLAR CELL

Building two spacecraft is an expensive business. The cost of the solar cells alone is estimated to be in the tens of thousands of dollars. AMSAT just does not have that kind of money, so those funds have to be raised somehow. When a terrestrial FM repeater is put on the air, the users normally contribute towards the cost of establishing and maintaining the repeater in operation.

Spaceborne transponders are many times more expensive than terrestrial repeaters (A-O-7 cost us $60,000, an identical commercially built unit could have cost $2,000,000). AMSAT is in the middle of a "sponsor a solar cell" campaign. If you can contribute at least $10.00, help in administering the program or have any constructive ideas on the subject, contact Tom Clark WA3LND at AMSAT, or send in your tax deductible sponsoring donation. All solar cell sponsors will receive a certificate attesting to their status.

THINKING AHEAD

Almost every day a new call is heard through the downlink of AMSAT's OSCAR 6 and 7. When the Phase III spacecraft is in orbit, the situation will change drastically. No longer will we be limited to 5000 miles, for a whole hemisphere will then come into range. For the first years of operation, any station in the Northern Hemisphere will be able to communicate with any other in that hemisphere for up to 15 hours a day, as well as with Southern Hemisphere stations for part of the time. This communication facility will be there irrespective of the state of the sunspot cycle, solar flares and most other phenomena that upset conventional HF band communications.

Consider what that will mean in terms of QRM!

On a "typical" HF band such as forty meters, a number of QSOs can take place on one frequency at any time, because depending on the time of day, two stations located in, say, Europe can work each other without hearing two stations in North America also working each other on the same frequency. It would also be possible for more QSOs to take place on the frequency causing minimal QRM as long as those other stations are well separated or within the dead zone (skip effect). In fact, this is normal for forty meters.

Now consider two meters. 144.12 MHz is a typical SSB frequency. At any given time, many QSOs could take place on that frequency, without causing any QRM at all to each other, because of the geographical spacing between the stations in QSO and the line of sight properties of 2 meter propagation.

What would happen if the characteristics of forty meters were suddenly superimposed onto the two meter band? Instant QRM! Stations all over half a world would suddenly start hearing one another on the frequency. Local QSOs could take place, simply by covering up more distant stations on the same frequency. DX work would be possible only if no locals appeared on the frequency at either end. Now take away the dead zone, and let the band be open to everywhere at the same time. Everyone is now a "local," and can be heard anywhere else.

This is what may happen to part of two meters (and 70 cm) when the Phase III spacecraft is in its final orbit. It is up to us to plan ahead to try and control the QRM so that QSOs can take place.

A two meter FM repeater puts a station in contact with any other one within, say, 60 miles or so for up to 24 hours a day.

The listed data tells you the time and place OSCAR crosses the equator in an ascending orbit for the first time each day. To calculate successive orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the first crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world, it will descend over you. To find the equatorial descending longitude, subtract 166 degrees from the ascending longitude. To find the time it passes the north pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR when it is within 45 degrees of you. The easiest way to do this is to take a globe and draw a circle with a radius of 2480 miles (4000 kilometers) from the home QTH. If it passes right overhead, you should be able to hear it for about 24 minutes total. OSCAR will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15 degrees from you, add another minute; at 30 degrees, three minutes; at 45 degrees, ten minutes.

OSCAR 6: Input 145.90-146.00 MHz; Output 29.45-29.55 MHz; Telemetry beacon at 29.45 MHz.
OSCAR 7 Mode A: Input 145.85-145.95 MHz; Output 29.40-29.50 MHz.
Mode B: Input 432.125-432.175 MHz; Output 145.925-145.975 MHz.

Orbits designated "X" are closed to general use. "ED" are for educational use. "BTN" orbits contain news bulletins. "Q" orbits have a ten Watt erp limit. "L" indicates link orbit. "N" or "S" indicates that Oscar 6 is available *only* on northbound or southbound passes. Satellites are not available to users on "NA" days.

The transponders on AMSAT's OSCAR 6 and 7 increase that range to 5000 miles, but only for 20 minutes or so, three or four times a day. The Phase III spacecraft will put a whole hemisphere in range for up to 15 hours a day. This means that round-table QSOs between stations in Europe, the U.S.A. and Japan could become commonplace. This would introduce a whole new era in phone patches, traffic handling, emergency communications, and educational uses.

It is these latter uses that will be instrumental in getting a place aboard the launch vehicle for the spacecraft. It's going to take a lot of planning to ensure that we utilize the Phase III spacecraft in the best way. One way to do it would be to split the passband into modes, similar to the voluntary band plans in effect in IARU Region 1 on all amateur bands. Starting at one end of the passband, there is a CW section, then an SSB section, with an overlap area for mixed mode contacts. The top end of the SSB section and the bottom end of the CW section could be used for traffic and messages where allowed by the licensing authorities. Then follows a segment reserved for SSTV and RTTY. Another segment is reserved for educational uses, including an Emergency Calling Frequency. The last section is a small one reserved for the use of the AMSAT Command Stations as an intercom frequency. It may also be used for announcements, similar to those presently being made on AMSAT's OSCAR 6 and 7. The actual locations of the assignments and the amount of passband allocated to each must be made by us as users, because it is voluntary and can only be enforced if the users agree to do so. The development of any kind of band plan *should be started now*, because it's going to take two years to get everyone to agree.

Your comments are needed. Comment on the type of band plan (if any), the amount of spectrum allocated to each mode, and on anything else.

Repeater Update

The following repeaters have been licensed and have gone on the air since the publication of the last *73 Repeater Atlas*. Other areas of the country will be updated in future issues. Watch for publication of the new *73 Repeater Atlas* soon.

FCC

BEFORE THE
FEDERAL COMMUNICATIONS
COMMISSION
WASHINGTON, D.C. 20554

In the Matter of

Waiver of Section 97.28(b)(1)
of the Commission's Rules

ORDER
ADOPTED: NOVEMBER 23, 1976;
RELEASED: NOVEMBER 24, 1976

1. The Chief, Safety and Special Radio Services Bureau, acting under delegated authority, has under consideration the waiver of Section 97.28(b)(1) of the Commission's Rules in order to establish a procedure for processing requests for multiple Novice Class written examinations. Under the present rules, an applicant for a Novice Class license in the Amateur Radio Service must first pass a test in the use of Morse Code before making an application that a written test be sent to the applicant's volunteer examiner for administration. In situations where one examiner has been tutoring many applicants, problems have arisen in the time delay experienced in receiving the exams by mail and then administering them after the regularly scheduled sessions of instruction have ended. It is anticipated that large groups of students will be concluding their Novice courses in the next few months and that a method for expediting applications will be necessary.

2. A waiver of Section 97.28(b)(1) will allow an examiner with several applicants to apply for the written examinations prior to successful completion of the Code test. To implement this new procedure, the Commission will require the following:

(a) Examiners must administer the tests to at least five applicants.

(b) Requests for exams must be received no later than thirty days prior to the date of examination.

(c) Examiners must continue to meet the eligibility requirements of Section 97.28(b): They must be twenty-one years of age or older, holders of a General Class license or higher, and unrelated to any of the applicants.

(d) Requests must include the number of tests needed, the date the examinations are to be given, the name and address of the examiner and a photocopy of the examiner's license.

3. Examiners are reminded that they will be held accountable for returning all used and unopened examinations, and that they are expected to establish a method of control to insure the integrity of each examination. All requests for examinations should be mailed to: Federal Communications Commission, P.O. Box 1020, Gettysburg PA 17325.

4. Accordingly, the Commission, by the Chief, Safety and Special Radio Services Bureau, under authority delegated pursuant to Section 0.331 of the Commission's Rules, ORDERS that Section 97.28(b)(1) of the Rules is hereby WAIVED for the period beginning November 24, 1976 and ending June 30, 1977.

FEDERAL COMMUNICATIONS
COMMISSION
Charles A. Higginbotham
Chief, Safety and Special
Radio Services Bureau

Ham Help

Under date of September 11, 1976, I wrote your magazine to the effect that I was an over-aged citizen disenchanted with CB, wondering how I could get into amateur radio, how I could accumulate in a hurry the knowledge that licensed hams already have, and requesting information on the sources of used ham gear. For your convenience I enclosed a stamped return envelope.

You did not personally answer my letter. You *did* publish my letter in the Ham Help column of the very next issue of *73 Magazine* which went to press!

That is when all hell broke loose!

Within a two week span following publication, I received more than two dozen letters, one from as far away as Sioux Falls, South Dakota, providing genuine assistance of one form or another. During this same period, I received at least a dozen phone calls, one of which was from as far as fifty miles away, again offering the kind of assistance I had hoped for in my letter to you!

In all of my previous experience, I had never encountered such willingness to be of help, and all of it offered without any expectation of monetary return!

As a consequence of your publication of my plea, I did enroll in a Novice class course at UMPG (although it had already run too many sessions for me to catch up), found a volunteer of assistance toward Novice within 10 miles of my home, located

Special Report

from page 15

channel spacing (e.g., 8 or 9 kHz) has also been addressed by the SWG. While Regions 1 and 3 have adopted plans to reduce channel separation as a means of increasing the number of channels, this scheme affects adjacent channel interference, the development of AM stereo, and poses serious conversion problems for the US which has developed its AM service largely around the use of directional antennas designed for use only on specific frequencies. Comments on this issue and the extension of the broadcast band to 1805 kHz are requested.

The International Broadcasting SWG indicated that additional spectrum was required, particularly at 3900-4000 kHz. We have not proposed any change to the band 3900-4000 kHz, which permits broadcasting in certain regions under specified conditions. Although the recent LF/MF conference rejects the use of single side band, we feel this technique should be examined and commented upon.

The *International Broadcasting* (SWG) requested retention of their present allocations of a total of 2150 kHz and additional worldwide allocations of more than 2000 kHz; this amount would double the current allocation and include approximately 20% of the spectrum available between 4 and 27.5 MHz.

The Commission currently licenses ten transmitters for operation in the high frequency bands allocated to broadcasting, approximately 5% of the total US broadcasting; the other 95% of US HF Broadcasting is conducted by the US Government through USIA and the Board for International Broadcasting. Presently, throughout the world, there are approximately 1500 transmitters on the air carrying about 22,000 daily frequency hours. Two or three international shortwave broadcasters operating on one frequency is a common occurrence. The US requirements for additional spectrum in the HF band are under consideration.

Citizens Radio

The Citizens Radio SWG requested an additional allocation of 1 MHz in the 26-28 MHz band, a 5 MHz allocation in the band 216-300 MHz with 220-225 MHz preferred, and a 10 MHz allocation between 470 and 947 MHz, preferably between 890 and 947 MHz. These are needed to meet the explosive growth of CB and to provide additional services such as channels for repeater operations, municipal service tie-ins, and weather information.

The SWG further requested that this service be redesignated as the "General Radio Service," and that this new service be recognized internationally by the inclusion of it and its associated spectrum in the ITU table of frequency allocations. The utilization of Citizens Band frequencies in the US is extensive by any standard, with the uses extending into nearly every area of personal and business communications. However, we are unable to endorse the principle of advancing an international allocation for a specific service, such as the "General Radio Service," particularly when the need for such a service has not been advanced on a large scale.

There is already a provision for the Mobile service between 27.5 and 28 MHz in the International Table, so no change is required, recognizing, however, that in the US the band 27.54-28 MHz is subject to exclusive government use. We are proposing that the band 220-225 MHz be allocated for shared use by the Mobile Service with the Amateur, Amateur Satellite and Radiolocation Services. Part of this band could be allocated domestically to the Citizens Radio Service, if it is eventually decided that this allocation would be in the public interest. As our table shows, we also propose to meet the requirements of the Mobile services by providing access to the band 890-947 MHz; use of these frequencies by the Citizens Radio Service could result from domestic rule-making.

Further, an effort to establish CB as the "General Radio Service" could well work against the expansion of spectrum desired by the Citizens Band SWG since future domestic allocation actions may well provide for expanded spectrum. Thus, we are proposing to continue the present international allocation at 26100-27500 kHz for Fixed and Mobile (except Aeronautical Mobile), which is used domestically in part by the Citizens Radio Service. While the actual desires of the SWG have not been fulfilled, we feel that our proposal will prove to be the most beneficial one for the needs of the service in the long range future.

Conclusion

As we have previously indicated in this proceeding, all participants should keep in mind the importance of the 1979 WARC results. Based upon past experience, decisions reached at this conference can be expected to provide the basis for international radio regulation policy for most of the remainder of this century. It is of the utmost importance to develop US proposals which effectively promote that combination of telecommunication uses which offers the maximum social and economic contribution to the national welfare and which also contain the flexibility necessary to accommodate important new applications of this dynamic technology as well as the unique requirements of our international partners in the ITU.

LETTERS

from page 126

wrote to Washington DC to Advertising, Credit, and Fraud, Margery Smith, Acting Director, Bureau of Consumer Protection, Federal Trade Commission, Washington DC 20850. Yesterday the mailman had a letter from Trigger — yes, just a *check. But Margery Smith did it.* Now I am going to *"burn"* a Blue Electronics Book for good. Took a FCC radio test yesterday and now I can move forward again after 2 years of waiting for parts.

My 73 to the publisher and thanks.

Frank J. Jelinek, Jr.

BALONEY!

The card is because I must take immediate issue with the Holiday issue, page 8, second letter, as follows: Baloney, Wayne, it IS that good and gettin' always better!

That's not my ego — I began writing for you because *73* IS the best. If I qualify for you, I stand well judged, and then I strive to do better each time, too.

Feel free to put this in "Letters." You have earned the praise — in spades — and in spite of IRS, big (phoney) business, and the stigma of CQ past. Hi!

Dave Brown W9CGI
Noblesville IN

I/O DOWN UNDER

I saw you needed articles for the I/O section of *73*, so I'm enclosing one. I could not think of anything more useful to a microprocessor than interrupts (boy . . . am I getting sick of typing that). I hope it will be of some use. If you want an article on programs (not programming, you seem to have enough of them), it's coming up next. Around here a small group of us are getting micros built; we have access to a resident cross-assembler to the Burroughs Computer for the M6800 with Mikbug — very useful. We also have a number of minis at university (at present I am a student at Auckland University doing computer studies and electronics) with interactive BASIC.

I am now working on an ALGOL interpreter for an M6800 (ALGOL is a high level scientific and general purpose language; it stands for ALGOrithmic Language, and has lots of nice features not found in FORTRAN). I'll let you know about that later. Probably some time in 1978-9, the way things move around here.

I enjoy reading your I/O section; keep up the good work.

Robert Leyland ZL1TRM
Auckland, New Zealand

HEURISTICS

The article "What Computers Can And Can't Do" in your Holiday issue was an interesting one, and has moved me to make two comments. The first is an answer to the question of unfair competition raised at the end of the article. The simple answer to this is that any station which receives any assistance during the contest automatically falls into the multi-operator category. Your readers must ask themselves if their stations, computerized or not, can compete with the likes of W3AU or W7RM. The second is a slightly more philosophical one, and open to debate. Since there is no well defined technique or algorithm for contest operating, the computer program must involve heuristics and, as a result, the personality and prejudices of the programmer will be built into the program. In short, the computerized contest station, although faster than its human owner/programmer, will probably not be a much better contest operator.

Robert A. Hyman K3OCN
Silver Spring MD

SCHULTZ COLLAPSES

Even though I may be considered one of your Associate Editors, I am going to sue you!! The bookshelf I had hung on the wall collapsed after I placed the 11/76 issue of *73* on it.

John Schultz W4FA
FPO New York

QUICK SERVICE

As the editor of *73*, I feel that you must be informed of the extremely fast service I received from one of your advertisers. The company I am referring to is Kemit Electronics, Sunnyvale CA.

They had advertised the G.I. chip AY38500 TV game chip for $29.95, so I sent them a check one week ago today. Lo and behold, today in my mail was a package from them.

I feel that such service should not go by without your knowing about it. I feel that these people should be put on your list of good advertisers.

Raymond J. Keefe
Montclair NJ

Briefs

from page 118

"Citizens Amateur Radio Service"; RM-2770, to legalize the use of any emission mode on any amateur frequency; RM-2771, to permit the use of ASCII on the ham bands; RM-2774, which would set up temporary licensing; RM-2775, to expand the operating privileges of Novices and Technicians; RM-2776, to create a new Special Radio Service on 11 meters; and RM-2780, aimed at revamping logging requirements for repeaters.

AMSAT is looking for money and volunteers in order to continue the amateur satellite program. A spokesman at their Washington office told *73* that the ten dollar annual dues of the approximately 3000 members is not nearly enough to keep the program going.

Two satellites are currently awaiting funds to finish their construction. The AOD satellite, which will probably become OSCAR 8, will feature 2 meter to 432 MHz and 10 meter transponders, as well as microprocessor control. The 144-432 transponder was built by the Japanese AMSAT group and the structure by a group of California members. Only the 2 to 10 meter transponder needs to be finished. It's being built at AMSAT Washington, with a projected launch date of September, 1977. An AMSAT spokesman said that if OSCAR 6 is still in operation at the time of the launch of OSCAR 8, OSCAR 6 will be put on "furlough" and will probably be used for educational purposes only. OSCAR 6 had an expected life of one year when it was launched in 1972 and is still going strong.

The AMSAT Phase III satellite has a projected launch date sometime in 1979. Its higher orbit would make contacts possible over a 15 thousand mile range, rather than the current 5000 mile limit.

Because of the new equipment in both satellites, higher power solar cells will be needed. AMSAT is suggesting that contributors send ten dollars to buy a single cell (or more if possible). Although how to acknowledge the contribution has not been decided, it's expected the contributor would receive a certificate of some kind.

AMSAT is also attempting to put together a group of volunteers to approach foundations and corporations for larger contributions, since they doubt individual contributions will be enough to keep the program going.

Volunteers, ideas, and contributions are needed to keep the amateur satellite program operational over the next few years. Contact AMSAT, Box 27, Washington DC. The phone number is 202-488-8649.

Harrisburg hams have four repeaters on the air. Central Pennsylvania Repeater Association has just added a 220 MHz machine to a 450 MHz machine, a two meter teletype machine, and the well-known 16/76 repeater. The teletype machine is on 147.975/.375 MHz. Services worth hearing from the RTTY repeater at Harrisburg include ARRL bulletins every day, detailed radio propagation reports from NBS and ARRL, National Weather Service condition reports and forecasts for the East Coast and the world daily, plus the Yellow Sheet. (Yellow Sheet is a daily listing of all amateur gear for sale to amateurs in their area.) *Newsletter* of the Nittany Amateur Radio Club, State College PA.

The FCC has shut down its Canadaigua Monitoring Station, replacing it with a Limited Enforcement Office (LEO). HF monitoring and related direction finding will be terminated, with inspections, investigations, and VHF/UHF monitoring throughout NY and CT taking their place under a much reduced staff arrangement. *RaRa Rag*, Bulletin of the Rochester Amateur Radio Association, NY.

An Indianapolis IN federal court has convicted a CBer on six of nine obscenity counts. He was charged with use of profane and indecent language on CB. The *Indianapolis Star* called the case a landmark decision, after a two week trial. Thanks to *The Radiop's Log*, Bulletin of the Westpark Radiops, Cleveland OH.

Using an FCC computer, Texas amateurs recently caught a pair of bootleggers. FCC officials caught up with them within two hours, and federal charges followed.

It's called "Amigos de las Americas" . . . a social service organization devoted to helping the people of South America. The Amigos have conducted immunization, dental, and ophthalmological programs for some twelve years, using amateur radio for communications with their stateside headquarters. If you're looking for something to do this summer, and can pay your own transportation (about $700 round trip) and expenses, contact the Amigos representatives in Houston TX at 713-481-2502 or 713-526-2771. Those who apply should hold Technician class or better, and be prepared to keep daily schedules with Houston plus inter-

staff communications, using either Amigos equipment or their own. The hams will be free to work DX or sightsee during off-hours. Stateside monitors are also needed 24 hours daily on 15, 20, and 40 meters. Countries participating during summer '77 include: Guatemala, Honduras, Nicaragua, Costa Rica, Ecuador, Bolivia, Paraguay, and Dominican Republic.

W1AW should have an improved signal soon. Construction is due to start on a 120' tower with stacked 4 element yagis for twenty and a 3 element yagi for forty. They look for a 10 dB improvement on forty and a bit less on twenty. *West Coast DX Bulletin.*

73 Publisher Wayne Green W2NSD is appearing weeknights on Boston's WGBH-TV. Wayne is a regular on Club 44, a show about leisure time activities. Subjects Wayne will cover range from ham radio (of course) to horseback riding and sports car rallying, along with microprocessors, CB, and more. That's Monday through Friday on channel 44 in Boston at 7:30 pm local time.

Edgecomb, Inc. of Torrance CA says it will produce the first microprocessor controlled 2m synthesized radio by spring. Company spokesman Ed Jay K6LOM (Signal 1-Multi 5000) says the rig will measure 2½ x 5½ inches, with 25 Watts output, programmable PL, scanner for priority channels, LEDs for frequency readout and decoding of repeater IDs, all for an expected list price of less than $500. According to Jay, the Edgecomb uses a 2901 chip (four bit slice) and will be available sometime this spring.

73 Advertising Director Bill Edwards WB6BED is expected back in his Peterborough office early in the new year, after suffering a mild heart attack. Bill recuperated at home, working part time out of his newly built ham shack. WB6BED can be expected to pack quite a signal from his Hillsborough diggings, especially on 40 and 20 meters.

Universal Subaudible Access Tone concept gains acceptance as the Chicago FM Club endorses the principle. This was first suggested on a broad scale by the Ohio Area Repeater Council, it seems, when the former president (Bill Mengel WA8PIA) of OARC placed the proposal before that body while in session at Delaware OH a couple of years ago. Subsequently, it was the subject of discussion at an FM forum during the Dayton Hamvention and has since been receiving attention in many areas. Briefly, the proposal advocates that guarded repeaters using subaudible tone for access (that are still "open" repeaters) provide a second tone access of 100.0 Hertz for use by transients running mobile and/or hand-held units. For example, Cincinnati repeaters using tone guard of 123.0 Hz would also install a decoder on 100.0 for travelers going through to access the system. It will, of course, require cooperation from those few systems now using 100.0 Hertz tone access to adopt a different tone as primary. Like all new concepts, it will be subjected to considerable discussion, but with the almost uncontrolled growth of repeaters, tone access is becoming an issue of major concern to repeater operators in populous areas. So, as tone access grows, the desire for a universal tone access for transients gains proponents. Lake Erie ARA *Newsletter*, Lakewood OH.

The FCC has made official a long held, but practically secret, policy on Novice license exam procedures. Under an order in later November '76, volunteer examiners can request up to five tests without first sending proof of an applicant's code proficiency. The FCC is apparently experimenting with the new procedure in the face of rapidly increasing Novice applications, because the rule will expire June 30, 1977. Address your requests for exams to FCC, PO Box 1020, Gettysburg PA 17325. FCC officials had informed *73* of the procedure, but requested we not publish news of it, fearing mass confusion would result in Gettysburg. The official notice arrived a week later.

New Products

from page 20

condition in a matter of a few seconds. I just pop the magnetic mounts in the trunk.

One unique antenna in the line merits mention. The PO-150 is a 144-174 MHz 5/8 wave that is designed for use *without* a ground plane. It fits a standard PL-259 socket and works wonders on an HT as a replacement for the rubber duckie. These are useful for non-metallic vehicles such as boats, recreation vehicles, and Corvettes. A conversion kit can be ordered to adapt it to base use by the addition of radials.

The 50 and 144 MHz models handle 200 Watts of power, while the 440 MHz model handles 150 Watts. Base coils are coated with epoxy for full weatherproofing. These antennas are made for full-time use and should last longer than the car. All are covered by an unconditional six month guarantee.

Larsen says that you can hear the difference with their antennas. I tend to agree. Their high quality products are unique and dependable. The Larsen should be the last mobile antenna you'll ever have to buy.

Depending upon the mount and whip, Larsen antennas sell over a large range of prices. For example, a quarter wave permanent mount sells for $8.50, while a 5/8 wave with a magnetic mount retails for $38.55. *Larsen Electronics Inc., 11611 NE 50th Ave., PO Box 1686, Vancouver WA 98663.*

TURNER HL6 MICROPHONE

Iowa-Turner Division of Conrac Corporation announces the availability of the Amateur HL6 microphone. This microphone has been designed specifically for the radio amateur who wants superior performance from a cardioid microphone, especially when vox is employed.

The Amateur HL6 has the capability of high or low impedance by selection on a slide switch inside the microphone. This fact, plus universal six wire switching, allows the Amateur HL6 to be easily installed with virtually all models of transceivers.

The Amateur HL6 has a flat frequency response from 50 to 13,000 Hz, which allows maximum speech intelligibility with a reduction of local noise interference. *Turner Division, Conrac Corporation, 716 Oakland Road NE, Cedar Rapids IA 52402.*

EICO IC SWEEP/FUNCTION GENERATOR

EICO, long a pioneer in the field of electronic test equipment, has introduced its new Model 390 Sweep/Function Generator.

In announcing the Model 390, Harry R. Ashley, President of EICO, stated, "It has long been EICO's policy to provide the professional technician and the home hobbyist with reliable test equipment at a moderate cost. By using the latest IC technology, we were able to develop a new breed of instrument which will rapidly overtake in popularity the traditional audio signal generator. This new .2 Hz to 200 kHz instrument is the practical answer to many of the signal source needs of design labs, schools, audio repair shops and hobbyists."

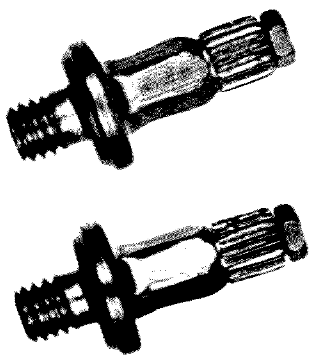
The Model 390 generates discrete sine, square, and triangle waveforms over the very broad frequency range of .2 Hz to 200 kHz, more than enough for the most exacting work. And, what's more, at the flick of a switch, you can have a choice of either linear or logarithmic sweep with a choice of slow, medium, or fast rates.

With its 50 Ohm output impedance and complete attenuation controls, the Model 390 can handle everything from checking the response of an audio amplifier to driving digital circuits, and with its low frequency triangle output, even driving servo systems! *EICO Electronic Instrument Incorporated, 283 Malta Street, Brooklyn NY 11207.*

GOLD LINE TERMINAL STUD KIT

A new Terminal Stud Kit for two way communications has been introduced by Gold Line Connector.

A Gold Line spokesman says the new kit (the #1105) was designed for batteries with side mounted terminals and that it provides the necessary connecting hardware for those direct-to-battery applications where standard battery studs do not. The 1105 lets you hook up communications equipment, tape players or automobile tune-up instruments easily. *Gold Line Connector, PO Box 893, East Norwalk CT 06855.*



SWITCHCRAFT ACQUIRED BY RAYTHEON

Plans for the acquisition of Switchcraft, Inc. by the Raytheon Company, Lexington MA, have been completed, according to a recent announcement by the two companies.

Upon completion of the acquisition early in 1977, Switchcraft will become a wholly owned subsidiary of Raytheon. Wilfred L. Larson, president of Switchcraft, who founded the company with Fred and William Dumke in 1946, will continue as president.

Larson said that "Switchcraft will maintain its program of marketing its products to electronic distributors and manufacturers through the independent sales representatives who have contributed to our company's success over the years.

"The new association with Raytheon is a big step forward for Switchcraft. It brings us the opportunity and means to expand our manufacturing facilities, which has become necessary to meet growing customer demands for our products. Also, we foresee the introduction of a number of new products to fulfill new customer needs." *Switchcraft, 5555 North Elston Ave., Chicago IL 60630.*

I/O EDITORIAL

from page 68

came out to an average of $2032 per . . . about what your shopping list will indicate. If that seems like a lot of money to you, then it is probably time for you to think seriously in terms of making your hobby pay off . . . perhaps by writing articles for one of the ham magazines. Ahem.

By way of throwing some further rocks in your path, I think you probably should not know that most of the fellows with going computer systems are planning to spend a bit more on them this coming year. Hold tight . . . the estimate of planned spending is also right around $2000. I suspect that those with running systems are now convinced that they really want to have a floppy disk to go with their machine . . . or perhaps a dual floppy. If you do decide to go the floppy route, be sure to check on the programs available . . . the disk and disk controller are the easy part; you still need a good disk operating system (DOS) and without it you are again up aforesaid creek. I know where you can buy a multimegabyte disk system, complete with an Altair compatible controller, for a few hundred dollars. All you have to do is write your own DOS . . . I forget how many man years IBM spent on a DOS recently.

We'll be having more and more ham oriented operating systems in *73*. If you've worked up any, please send them in for all of us to enjoy. You'll have to read *KB* for most of the non-ham programs . . . and we'll have a lot of them.

While the above probably has not galvanized you into anything but inaction, I did think I should level with you as to the honest state of the field of microcomputers. On the positive side, I'm in touch with thousands of computer hobbyists and they are having the time of their lives. A surprising percentage of them are hams and you can bet they will be doing a lot of ham stuff via microprocessor. Sit tight if you want, but you are missing out on fun. These are days that will never come again and those who are there will never regret it.

Corrections

A correction for my article "Superprobe," in the Holiday issue, on page 92 and 93. Resistor R9 is shown incorrectly installed from pin 3 of IC2 to ground, and should be moved to the other side of the capacitor C3, or from pin 5 of IC2 to ground. If wired as shown, the symptom will be that the pulse LED will remain lit at all times.

C. W. Andreasen WA6JMM
Van Nuys CA

In "Mobile Smokey Detector" (Holiday *73*, page 32), it was stated that since power levels are below 100 mW, it might not be necessary to have a ham license to operate in the 10.5 GHz band. This was incorrect. The band requires a license for any power.

The CT7001 IC described in December's "CT7001 Clockbuster" is no longer available from Cal-Tex Semiconductor. Fairchild Semiconductor is manufacturing the IC under the designation FCM7001. They are available from *James Electronics, 1021 Howard Avenue, San Carlos CA 94070* for $7.00.

Our apologies for failing to mention that the author of "A 60 Foot Antenna on a 20 Foot Lot" (Holiday issue, 1976, p. 138) was Norman Rossignol WB6DPR. The editors extend their apologies for the error. The article first appeared in *World Radio News*, January, 1976.

Please be kind enough to publish the following correction and addition to my February, 1976, article "Put Your SB-10 on 160m."

Because of the inexactness of the method of extrapolation I used, the value of the phase shift capacitors that I stated to be 1240 pF should be corrected to 1744 pF. Since 50 Ohm phase shift resistors are used to produce 45 + 45 = 90 degrees shift the following formulas may be used to calculate the phase shift capacitors:

$$X_c = 50 \text{ Ohms} = \frac{1}{2\pi FC} = \frac{1}{(6.28)(1.825)(10^6)C}$$

$$C_{pF} = C_F(10^{12}) = \frac{(1)(10^{12})}{(6.28)(1.825)(10^6)(50)} = 1744 \text{ pF}$$

The use of 1744 pF capacitors will result in maximum SB suppression in the SB-10. In addition, one should add a 50 pF capacitor is parallel with the output connector on the unit to resonate the SB-10 output as a pi network. As Leeds Radio Co. no longer supplies these capacitors, they may now be obtained from Cap Electronics, 134 Duane St., New York NY 10013.

NEVER SAY DIE

...de W2NSD/1

EDITORIAL BY WAYNE GREEN

Since one of the basic reasons for the amateur "service" is the pioneering and inventing we do (97.1b), the FCC is going against its own rules when it prevents amateur experimenting and pioneering. Why doesn't some national club haul the FCC into court and force them to obey their own rules?

The FCC has a long history of making it somewhere between difficult and impossible for amateurs to live up to 97.1b. Their recent refusal to permit experimenting with ASCII on the low bands, using as an excuse the bandwidth docket which is under consideration, is a typical example. Here we have a docket which the FCC admits can take several years to conclude and it is used as a reason for preventing the development of amateur techniques. Many FCC rulemaking procedures take from three to five years to complete, and amateur radio just cannot afford to move at such a snail's pace.

This is no worse than the excuses used in the past to prevent amateur experimenting . . . for years the FCC refused to allow amateurs to use any mode of emission which their monitoring stations were not set up to copy. Amateurs were held back for years in RTTY developments as a result of this restriction.

If the FCC has no real intention of permitting amateurs to live up to the rules as written, then they should at least be honest about it and delete 97.1b from the regulations . . . and they should explain to us why they have deleted this.

When you consider what amateurs have been able to do, despite the efforts of the FCC to smother the ham creative urge, it is a miracle. I wonder what might have developed if we hadn't had to fight the FCC every inch of the way?

I'm exaggerating, you say? Take a look at the way repeaters developed before the FCC got into the act. We had things really moving along . . . with a repeater network up and working on a daily basis where a chap could talk from San Diego to Phoenix to San Francisco. I stood on a street corner in Las Vegas a few years ago and talked with a chap in San Diego, one in Los Angeles, and one in Phoenix in a round table. The FCC outlawed this, as they did crossband . . . for instance, we added ten meters and the repeater users were able to talk from an HT via two meters with amateurs all around South America. I set up another repeater for 2m-20m work and worked DX while walking anywhere around town with an HT.

More and more repeater groups were expanding the services of their systems . . . some to six meters, some to 220 MHz, some to 450 MHz. All this got stopped when the repeater regulations were made into law . . . and the result has been a serious drop in the activity on both 6m and 220 MHz. How can we get the FCC to leave us alone so we can try different systems . . . invent new modes . . . and pioneer new ideas?

For a while, after the January, 1974, hearing before the Commissioners, it looked as if the Commission was going to try to turn over a new leaf and ease up on the restrictive amateur regulations. They have, to some degree, followed through with this, but they've hardly made the amateur service an example of deregulation.

The FCC might work on the basis of permitting experimentation during discussions of rule changes rather than prohibiting it. If they eventually prohibit a certain mode, then we would have to stop using it. This would be better than waiting three to five years to even start experimenting.

Speaking of the bandwidth docket, perhaps we would do better if we convinced the FCC to do their deregulation bit by bit instead of in big lumps. One of the major problems with this docket was the tying in of killing amplitude modulation with a lot of desirable changes. Amateurs don't like AM much on the low bands, but they are not completely convinced that it should be killed off by fiat. This could prevent experimentation with double sideband techniques, and these hold great promise for better band densities with less interference than anything in view for single sideband. If we can get five times as many stations in a band with less interference than we're suffering with SSB, why should we prohibit experimentation? Synchronous detection may turn out to be one of the great undeveloped fields of amateur radio. Or it may not . . . but should one for me. The next time you see your ARRL director or write him, ask that he get the League to work in the same direction . . . and make sure he lets you know what is happening.

BASIS AND PURPOSE: THWARTED?

While rereading the FCC regulations for the umpteenth time — it was during some work in cooperation with the FCC on a project to update the ham exams — I got to thinking about the meaning of the first paragraph, 97.1 Basis and Purpose. The language is so muddled and exact interpretation is impossible — a strategem used by government bureaus which permits their continued growth, while providing good flank protection.

The proposed Novice exam material seemed to be a bit scant as far as the basis and purpose of amateur radio was concerned. It had boiled the five parts of 97.1 down to three, so I looked at the rules to see what had been omitted. Two parts had been left out. One turned out to be 97.1e, the enhancement of international goodwill. I was sort of sorry to see that on the way out — perhaps it was an oversight — or maybe it didn't seem all that important anymore to the FCC.

The other omitted part of 97.1 was a legitimate deletion. The actual intent of 97.1 is to define the basis and purposes of the *rules*, not of the amateur service, but since four of the five parts of the paragraph apply to both, 97.1 itself has come to be thought of as being a statement of the basis and purpose of amateur radio. This part is most significant in the light of recent rule changes and proposals for rule changes. 97.1c states that the purpose of the regulations is for the "encouragement and improvement of the amateur radio service through rules which provide for advancing skills in both communication and technical phases of the art."

That seems simple on the face of it. Yet, as the ONLY rule applying solely to the purpose of the rules themselves, it would seem that it should have a binding effect on the Amateur Division of the Commission when they are preparing new regulations for enactment.

The rules then should encourage

recent major rules changes from this viewpoint.

The "incentive licensing" rules: In what way did they contribute to the advancement of communications or technical pioneering? The taking away of band segments to force amateurs to go back for a new license exam would not seem to be even remotely relevant to either. The Commission apparently got carried away with doing the bidding of the ARRL, even though it was inconsistent with the basic mandate laid down by its own rules.

The repeater docket was most restrictive to those interested in pioneering and technical experimentation. We've been promised that the most severely restrictive aspects of the docket will be modified, but still we had a good example of the Commission going directly against its most basic basis and purpose, as stated in 97.1c.

How about recent dockets? How much of the change proposed in the rules can be justified as being consistent with the mandate of 97.1c? What changes will encourage the development of communications skills? Will any parts of it encourage technical developments or the pioneering of new techniques? Let's really look closely at the dockets with these basic guidelines in mind and include this in our comments we file with the Commission – with 14 copies.

Is the taking away of RTTY and other such privileges from the General class and Tech licensees consistent with 97.1c? Will the goal of having them be relicensed as Advanced or Experimenter class licensees in any way be consistent with 97.1c? It is possible that the Amateur Division of the Commission has gotten its sights askew and is aiming us at some goal not specified by 97.1, and it is difficult to see how forcing us to pass more and more advanced FCC exams for higher classes of license is consistent with any of the parts of 97.1, though it is easy to see how it is quite *inconsistent* with 97.1c.

One of the reasons for proposed rule changes has to do with getting more amateurs. This is a good goal, undoubtedly, but it is in no way consistent with 97.1 – there is nothing whatever in there about getting more amateurs. Another purpose has been to get away from the problems of faked mail order licenses. This, too, is probably a good goal, but difficult to justify under 97.1 . . . particularly since there has been no real evidence that the problems involved are serious enough to warrant an enormous upheaval.

Since 97.1c says the rules should provide for enhancing communications skills, we must ask how putting restrictions on the use of a license work in this direction. The more restrictions there are, the less communications skills are going to be enhanced . . . right?

COMMUNICATIONS SKILLS

What amateur activities are best for developing communications skills? Just about any on-the-air activity, possibly with the exception of plain

old rag chewing, might be considered beneficial in skill developing.

Sending and receiving CW is a skill. Rapid typing on RTTY is a skill. Finding Oscar and making contacts takes skill. Sorting out the pileups to get a rare one on either phone or CW takes a good deal of skill. Contests sort out the unskilled in short order.

What in our recent rule changes has been added which would tend to encourage the development of skills? Do we do better to require someone to take an exam and prove he knows the theory of SSTV before we let him get on the air and operate with it? This is part of what we're doing with Docket 20282, and it seems like nonsense to me.

If we want people to develop skills in working with SSTV, we want to first of all remove as many obstacles as possible that are preventing them from developing these skills. We want to get them on the air with SSTV as quickly as possible, then they'll have the incentive to learn and be in touch with the people who can teach them. I didn't know beans about SSTV when I went on the first time.

I knew even less about RTTY the first time I got on the air on that mode, but my interest was stirred and I soon learned all I could. RTTY was so much fun that I had to know more, to build equipment and to get on more bands. We were stuck up on 2m and 11m in those days and FSK was illegal on the low bands. I got on 80m just sending mark signals and had a ball. We put an RTTY repeater on 2m in 1948.

Communications skills will best be developed, I think, if we keep the restrictions to a minimum and encourage new modes, new ideas, and the fun of it all. One thing is for sure, and I doubt if I will get any disagreement on this: The one single aspect of amateur radio that is just about the *least* fun is taking an FCC exam.

TECHNICAL SKILLS

The more the FCC can do to encourage amateurs to experiment and develop new ideas, the more value the amateur service will have — and this is consistent with 97.1c. Just look at recent technical developments: Amateur pioneers are hard at work with incredible circuits for SSTV, digital timers for Oscar alerts, Morse code to RTTY converters and vice versa, synthesizers for everything, computer applications for amateurs, sophisticated repeater controls — the list is almost endless . . . just look over the articles in *73*.

Instead of making these developments more difficult and hamstringing us (pardon), the FCC should be fanning the flames of interest and enthusiasm. They should be coming out with rules which would continue to remove more and more of the restrictions so we can work with pulse technology — with telemetry — and all the other far out ideas which might prove valuable if pioneered.

We have plenty of band room for new ideas. Why have we been prevented from having repeaters on ten meters when the band is virtually dead? Why are we so restricted on six meters when that band is a wasteland? Look at the restrictions they put on 220 MHz . . . and for what? No sooner did amateur repeater groups agree on standards for repeaters than the FCC shot them down with subband allocations. Insane! Has the FCC *ever* had any success in trying to read its crystal ball? And yet, this is what was going on . . . they divided up a totally unused band on the basis of what might someday happen, provided there were no unforeseen technical developments . . . and that is one thing you can depend on . . . amateurs will come up with unforeseen technical developments.

Just take a look at the 146-148 MHz band . . . in the early 60's that was and had been virtually deserted for almost 20 years. Loud voices were asking that it be turned over to CB. Then came repeaters, and within a few years this unused band had more amateurs using it than any other ham band. Use expanded very rapidly until the FCC got into the act and passed rules which stopped its growth for a while . . . then, after the biggest battle in the history of the hobby, the FCC (Walker) backed down and FM began to grow again.

Let's try and keep the FCC from putting through more and more restrictions which interfere with amateur pioneering and the development of communications skills. Remind them of 97.1c every time they start to make life difficult for us.

CAN HAMS REALLY BE TRUSTED?

Though I know of nothing in the FCC regulations which specifies that amateurs be self-policing, the fact is that we have done a rather good job of this and we accept it as a responsibility . . . some more than others, unfortunately. I would like to see more amateurs be serious about this.

The major growth of FM repeaters on two meters was almost totally without FCC interference. The first reaction of amateurs to mutual repeater interference was one of frustration . . . then repeater wars . . . and finally the development of repeater coordinators and repeater councils. To me this whole thing was an excellent example of the true amateur spirit. Even the hottest of heads eventually were calmed down and brought around to a reasonable and cooperative solution to the problems.

It was this example that was laid before the FCC at the hearing before the Commission in January, 1974 . . . a hearing demanded by the amateurs and ignored by the ARRL. On the strength of this proof of amateur responsibility, the ball was put in motion to deregulate us. This has resulted in a reduction of about 25% of the rules so far, and a lot more deregulation is under consideration. These things are monuments to the trust and foresight of FCC Chairman John Wiley, Charlie Higginbotham and Johnny Johnston.

The repeater problem wasn't the first instance of good amateur cooperation by any means. Whenever emergencies come along, amateurs drop their differences (which are many . . . like any other mixed group) and cooperate. And older timers will remember the "gentleman's agreement" as far as sideband was concerned on twenty meters. With very few exceptions, amateurs turned out to be gentlemen and virtually all sidebanders kept to the high end of the band, with the AM on the lower end of the band . . . and this despite the fact that there was little DX to be worked from the high end . . . it was all on the low end.

It is my impression that amateurs are perfectly capable of making gentlemen's agreements . . . and keeping them. Some of our self-proclaimed policemen aren't as subtle as we might like, but I'd rather have a nerd rattle the chain than no one at all. When you hear things going wrong, for heaven's sake speak up and see if you can pour some oil on troubled waters. It may be a guy with his mike up too high . . . a chap who got his switches backwards and is calling in the DX band and listening in the U.S. band . . . or someone stretching the bounds of decency on any band.

The fact that many amateurs have the feeling that they only have to watch out for FCC monitoring stations does not help matters. The FCC would do us a big favor if they were to announce that they would no longer issue citations for infractions of the rules, for this would forcibly make all amateurs aware that it is the responsibility of every amateur to uphold the honor and reputation of the group. I think we would very quickly be rid of the unspeakable garbage a few 75m AMers are putting out . . . and the disgusting behavior on a few Los Angeles repeaters. Even CBers wouldn't put up with rot like that!

The frequency coordinators for repeaters have been particularly protective of non-repeater interests, oddly enough. Most of them bend over backwards to make sure that repeater groups stay out of the way of all the other users of the VHF bands . . . AM, SSB, RTTY, Oscar, Moonbounce, DXing, meteor scatter, ATV, etc. We seem to be in much better hands when we are governing ourselves than when we are depending on the FCC . . . and the action sure is a lot faster. Many FCC actions are sped along from proposal to rule making in *only* four or five years, while some drag on for eight or ten. This is a real drag for amateur radio, since most of our significant developments sweep in and are accepted by us way before the FCC can get organized to cope with it rulewise.

The FCC reaction to repeaters was a good example of their fast work . . . by the time they got around to screwing up the works (royally), repeaters were too big a deal to get killed off. Obviously the FCC does not read its own rules . . . as I have written earlier . . . where they are supposed to encourage amateurs to pioneer and invent. Even in 97.3a they define the amateur radio service as "a radio communication service of self-training, intercommunication, and technical investigation carried on by amateur radio operators." Note that technical investigation part and ask any old-timer how many times the FCC has done just about everything in its power to stall same.

Amateurs, left to their own ends, might come up with even more fantastic developments than they have already . . . and, in case you've forgotten, chalk up FM, NBFM, SSB, and SSTV (so what else is there?) all to amateur inventing and pioneering. For years the FCC prohibited any amateur transmissions which could not be copied by all FCC monitoring stations . . . how about that for locking the door on developments? If we were permitted to be our own bosses, and I don't mean via ARRL, I think we could set up our own system for coping with the needs of progress . . . and on a speed which would be more geared to reality.

Why did I single out ARRL there? Their record on repeaters is typical . . . and a model of what service we get from them. They tried to ignore FM and repeaters for years . . . then, when it could no longer be ignored, they tried to step in and take control. Their recent ARRL band plan for the repeaters has battles going on all around the country because it is so out of touch with reality. ARRL is great for what it is designed for: radio relays. Their traffic system is fine and a service of which to be proud. Their record in other areas is execrable.

If we can't get quick action from the FCC on our needs . . . and we can't depend on the ARRL, what can we do? To whom can we turn for help?

How about starting with our repeater councils . . . we have them spread all around the country and they are already responsive to the will of the grass roots via representatives from the repeaters they serve. We might set up a yearly meeting (or every other year) where each council would field two representatives to decide upon the "gentlemen's agreements" for the next year or two. This would give us speed and responsiveness. It would keep the cost down, too, since there might be only about forty or so repeater councils involved.

On the other hand we might do better with a week-long national convention where the delegates were sent by interested clubs. This activity could become a major activity of most ham clubs . . . in which case we could have a couple thousand delegates getting into the act . . . probably every two years. That would be a truly democratic system.

When you stop to think about it, a structure starting with the local clubs expressing their views to a council of clubs makes a lot of sense. And a group of 80 delegates might get a lot more work done in a shorter time than 2000. The ITU system of breaking problems into separate committees for discussion gets things done quickly . . . then the committees bring their recommendations to the whole group for ratification.

In order for the actions of a conference such as this to have any validity, we would need a mandate

BE MY GUEST

visiting views from around the globe

C'mone Texas Salt Rat...

The scene is a Washington cocktail party at the home of an influential congressman. Guests from government and business are milling about, socializing and discussing the issues of the day or whatever. Suddenly the low volume of a local dinner music FM station is shattered by the deafening roar of undemodulated single sideband: "Come on Texas Salt Rat . . . this is the Maryland Grease Monkey . . . you got a copy?" Two blocks from the congressman's home, a CBer, operating illegally out of band with a broadband linear amplifier, strains his ears against the static, then starts to call again: "C'mone TEXAS. Ya got this here MARYLAND state . . . MARYLAND . . . MARYLAND . . . MARYLAND, C'MONE?"

The cocktail party, by this point, has shifted gears from the issues of the day or whatever to "those damn CBers," or worse, "those damn hams." The congressman, highly irritated, is on the phone by the time our CB friend cranks up the power for call number three, calling an aide to FCC Chairman Richard Wiley. "The folks back home have been writing me about this damn interference," he tells the aide, "and it's high time you guys got over here and did something about it!"

Needless to say, the congressman and a large number of his Capitol Hill colleagues have begun to put the wood to the FCC. When congressmen talk, the FCC listens. And what the FCC has been hearing a great deal of lately are interference complaints. In fact, last April the FCC stopped counting them after passing the 100 thousand mark. The axe is about to fall, and amateurs everywhere better be sure they're not in the way, because it is much later than most of us think.

Meeting room #6 at the Hotel Sahara's Convention Space Center in Las Vegas: Thirty ham radio equipment manufacturers, worried over press reports of an impending linear ban and type certification of ham gear, meet with FCC representative Dick Everett. They learn a proposed rule making is on Chairman Wiley's desk — in general, it would ban the manufacture and sale of linears capable of 24 to 35 MHz operation and force type acceptance. It is the eleventh hour, and ham radio has no lobby in Washington (ARRL can't lobby due to its non-profit status). The organizers of the SAROC meeting (Dentron's Dennis Had and Bob Levine) suggest formation of a manufacturers association, and the group is founded. It's called ARMA, the Amateur Radio Manufacturers Association.

ARMA was formed to encourage high standards and ethics in the ham radio industry, to promote the general growth and welfare of amateur radio, to work toward favorable rule making and legislation for the benefit of amateur radio, to function as liaison between the manufacturers and the FCC, to encourage public relations functions for the industry, and to collect and disseminate market information to the members. Two classes of membership were set up: full membership for domestic manufacturers and importers, and associate membership for publishing organizations, dealers, and other interested parties. The list of organizers reads like a "who's who" of the ham radio business.

The week after Las Vegas, ARMA sent a four man committee to Washington. They were able to see several FCC Commissioners, Senator Barry Goldwater, FCC Chief Engineer Ray Spence, and Enforcement Chief Richard Smith. One of the committee members, Marv Druskoff (VHF Engineering), described their greeting at FCC headquarters this way: "They wanted to know where we'd been, where we were when they needed us." The committee learned that the linear ban proposal had been written by two FCC staffers, without the benefit of outside ham help. Few specifics could be learned about the proposal because it had gone so far along in the FCC hopper, rushed through, in fact, in face of increasing complaints from Capitol Hill and pressure from the all-powerful broadcasting lobby. The broadcasters, ARMA learned, were worried about lost revenue as TV viewers switched to channels not affected by the CB interference. The TV lobby, Senator Barry Goldwater K7UGA told the committee, is so strong that it has twice managed rejection of his bills aimed at forcing built-in high pass filters and better shielding of TV receivers. Senator Goldwater assured the ARMA committee he'd try again, and support them in every way possible.

Back at the FCC, the committee members were hard at work trying to win delay of the linear amplifier ban, in hopes of suggesting engineering solutions. "We're working on the idea of pre-filtering with an 8 pole filter to eliminate 27 MHz," says Dentron's Dennis Had. "If disconnected it would have to totally disable the amplifier, because the FCC won't stand for any more easily clipped jumper wires." At deadline, engineers in Ohio, Pennsylvania, and California were working on such a system, along with several other ideas, but the question of a delay rested with the full FCC, which was scheduled to meet on the subject January 26th.

In Had's words, "We told them they'd waited two years, so why not put it off another 45 days?" ARMA was also working on point of sale control to prevent non-licensed people from buying equipment. Had says such controls would have to have regulatory backing to avoid problems with the Federal Trade Commission. (The manufacturers, by refusing to sell gear to offending dealers, could open themselves to legal action without federal backing.) Had told *73* he was optimistic, but realistic, on delaying the linear ban. As he put it, "It may have gone too far before we got there."

At best then, the notice of proposed rule making on the linear ban may turn out to be more general then it would have been if ARMA didn't get to the FCC when it did. The rub is that the manufacturers are afraid the FCC will bow to the Capitol Hill and broadcasting industry pressure . . . and make a move designed to be expedient, a move that could really hurt ham radio in the future. That, by every measure we could find in preparing this report, is not the FCC's intention. As one member of the ARMA committee put it, "They've got a problem and they need a solution . . . and they don't want to cripple the hams in solving it."

At the root of the interference problem is the FCC's placement of CB on the 11m band. It made it all too easy for amateur equipment to be used on CB, and the amazing growth of outlaw activity and the TVI-RFI problem is the result. ARMA members were told by high-placed FCC officials that the mistake would never happen again. Manufacturers have played their part as well. The smell of easy money has impaired the judgment of more than one company. The FCC, *73* has learned, has a list of the "pirate" manufacturers, but cannot stop them from making broadband amplifiers of questionable quality under the guise of 80 through 10 meter coverage. The "catch 22" is a loophole in the FCC's ban on broadband amps to allow for amateur coverage of 10 meters. Of course the quick buck manufacturers got around it by including bandswitching for 80 through 10 meters, switching that in most cases only cut power output down on all bands but 27 MHz! FCC tests have shown some pretty questionable engineering on the broadband amps, like tricks to build up forward power on built-in swr bridges (in one case pure ac was coupled into the circuit!). Another FCC amplifier test reportedly found power output in excess of 300 Watts, but when a 27 MHz filter was put across the output, the rf at 27 MHz was down to about 40 Watts! (It's not hard to understand where all those TVI complaints are coming from, is it?) The thing that really hurts on the FCC end is the placement of advertising (in *other* ham magazines) for these bootleg linears. In the absence of a viable ham radio lobby (like ARMA), the FCC really didn't have much choice but to plug the loophole, to ban linear amplifiers capable of 11 meters.

By the time this issue reaches you, a rule making proposal will probably be public. It could mean legitimate amateur amplifiers will stop at 15m, or traps will be built in to prevent operation on 11m. It will *not* stop hams from home brewing their own 10 meter amplifiers, and it won't outlaw existing equipment. It *will* require type certification of commercial amateur equipment, a burden the manufacturers have assumed for some time was on the way.

Okay, you're saying, a ban on newly manufactured linears covering 11m won't clear up the TVI mess . . . and you're right. But it will, argue FCC staffers, stunt the growth of out of band activity and power amps on the regular CB channels. The second step is education, using the same approach that's worked with ham radio — peer pressure and self-regulation. It may not be long before TV commercials and magazine ads begin pushing *legal* CB operation. Maybe a "Smokey the Bear" character warning CBers that the guys running amplifiers are only hurting everybody else since they mop up several channels at a time.

Another thing: A lot of the out of banders (and regular CBers as well) think of themselves as hams. They use a peculiar mix of ham and CB jargon in a format typical of our beloved (and often boring) QSO. When blindfolded, most of us would swear we were listening to 75m if it wasn't for an occasional "mercy sakes" or "come

on back." Listen for yourself both above and below the 11m band ... the typical SSB QSO covers the weather, equipment, antennas ... and sometimes several thousand miles. We still don't know if it was a joke or what, but the Post Office recently delivered a *Swiss* CB QSL addressed to a Peterborough CBer! (We still haven't found the CBer ...)

Fact is, it's those guys, with stations rivaling many amateur installations, who are the prime candidates for ham radio. Reaching them is the problem. The best way to do it is on the local level — include a welcome to CBers at your next auction or hamfest. Be sure all PR mentions a *local* address or phone number to find out more about ham radio. And don't forget the shopping centers — a good exhibit and a few friendly club members can go a long way. Another idea is to hand out back issues of your favorite ham magazine (and copies of the other ones, too). A lot of hams are doing it already, but I haven't heard of any clubs distributing magazines — if there are any interested, drop me a line.

So, in the midst of proposed bans on linear amplifiers above 24 MHz, type acceptance of ham gear, strong growth in the amateur ranks, and 40 channel CB, what's the future of ham radio? It *has* to be positive.

For one thing, there are the FCC assurances that CB allocations and ham bands will never be placed near enough together to cause the kind of problems we've seen on 11 meters. That's led to several sighs of relief regarding 220 MHz and Class E. (As reported last month, ARRL hopes to swap the 900 MHz WARC allocation for CB allocations at 220 MHz.) We've also heard of tests going on to determine how useful 900 MHz would be for CB, with interesting results. There is, of course, no skip, and coverage seems comparable to 27 MHz. It's only logical to see 900 MHz CB repeaters, complete with autopatch, in the future.

But what about 10 meters? Indications are that the loss of newly manufactured commercial amplifiers for 10m will not slow the band's growth. 28 MHz, according to sources both in industry and government, would have been opened to a new class of licensees months ago, if it wasn't for the tremendous volume of CB and ham applications coming into the Gettysburg computer facility. It all begins to fit together: multiple choice code exams, expansion of Technician and Novice class privileges, the dropping of "N" prefixes for Novices ... the Communicator class is just around the corner, and it looks like 10m will be added to the previously discussed 220 MHz allocation for Communicators. (In the same vein, the FCC would probably consider granting Technicians equal status on 10m.)

The implications of all this for ham radio are unclear. For one thing, there are too many variables to be sure Communicator class licenses will become a reality in the near future. For another, we don't know whether the 220 MHz for 900 MHz swap with the CB interests will work (that largely depends on those 900 MHz tests we mentioned). There is also the question of WARC, and the international situation (see *73* Special Report, February, 1977). The best assessment is probably Dennis Had's: "I'm optimistic but realistic." That's a good attitude for all of us.

RFI/TVI - An Analysis

Radio frequency and electromagnetic interference from a phenomenally growing number of sources, such as CB sets, consumer electronic devices, video games, computers, switching power supplies, ignition systems, and industrial, scientific, and medical equipment, has reached proportions beyond the effective control of the understaffed Federal Communications Commission.

The majority of complaints (87%) of interference to home electronic entertainment equipment involve CB transceivers. CB units have interfered with nearly every mobile and fixed communication service, including business, industrial, law enforcement, utilities, aircraft, and other public safety devices.

However, CB is not the only culprit, as garage-door-opener transmitters, industrial rf heating, medical diathermy equipment, community antenna television systems, super power FM stations, and auto ignition systems contribute their share of RFI. Compounding the RFI/EMI problem for the FCC is the appearance of millions of potential sources of interference from consumer devices such as video games, computers, switching power supplies, etc.

To combat this problem, the FCC has taken two steps, the first being the adoption of stricter regulations for RFI emitters like CB equipment. Also, the FCC has proposed revisions which will strengthen two crucial sections of its regulations, Parts 18 and 15. The former regulates industrial, scientific, and medical equipment, while the latter covers devices with low power intentional radiation, such as wireless intercoms, and devices with unintentional radiation, such as electronic games.

Historically, the FCC has considered the emitters of interfering radiation the villain, but with emitters growing by the millions, it is now considering imposition of regulations requiring the manufacturers of consumer entertainment electronic equipment to make their products RFI/EMI proof. At present, the FCC has no legal authority to do this, but an amendment to Section 302 of the Communications Act would rectify this.

At present the harmonic suppression requirement for CB transmitters is -60 dB below the carrier. The CB manufacturers claim that this amount of suppression in a legally operated transmitter will not cause RFI to TV sets, and when it does happen, it is the fault of the wide-open front end of the TV set. However, Joseph DeMarinis, director of engineering for GTE Sylvania, disagrees. He states: "The filtering and shielding of a TV set is an order of magnitude, or more, better than the state of the art of CB transmitters."

Less known is the fact that the radiation from oscillators of CB receivers has been creating interference problems for three public services: the Power Radio Service used by electric, gas, water and steam utilities in the 37 MHz band; the aircraft services band, 100 to 135 MHz; and the Forestry Conservation Service operating on 151.205 and 151.400 MHz.

Interference to Power Radio Services stems from the heterodyne type of frequency synthesis used by many 23-channel CB transceivers. To minimize the number of crystals, the 23 oscillator frequencies are obtained by heterodyning the outputs of two oscillators. One uses crystals at 37.6, 37.65, 37.7, 37.75, 37.8, and 37.85 MHz. The other has crystals at 10.180, 10.170, 10.160, and 10.140 MHz for a combined total of 23 channels.

The 37.6, 37.7, and 37.8 MHz frequencies happen to be those used by the Power Radio Service. To alleviate interference of all three services, the FCC amended Part 15C by adding a new Section 15.59 that requires the certification of CB receivers to new low limits of oscillator radiation. The manufacture of CB receivers not certified to meet the new requirements must cease no later than Aug. 1, 1977.

Illegal or bootleg rf amplifiers increase the CB transmitter many times its legal 4 Watt limit. These amplifiers are made available to CBers by a few irresponsible CB suppliers who manufacture amplifiers, ostensibly for amateur use, but which can be driven by only 3 or 4 Watts. As most amateurs have exciters with about 100 Watt capability, the subterfuge is quite obvious.

To help combat bootleg activities and other sources of CB interference, the FCC's Field Operations Bureau is investigating a random selection of TV interference complaints. It is engaged in the following activities:

1. Monitoring a CB station unannounced to determine if a linear amplifier or other illegal accessory, such as a VFO or power mike, is used.

2. Inspecting CB station equipment for spurious emissions through the use of spectrum analyzers.

3. Inspecting a complainant's TV receiver for received signals and antenna quality.

4. Installing high pass filters on the TV receiver and low pass filters on the offending CB set.

5. Making a neighborhood survey to determine the impact of interference on the local area around a CB set.

Most of the FCC regulations governing consumer electronics devices and equipment appear in Parts 15 and 18 of the Commission's rules, but Part 15 has not been amended since 1948, and the basic technical specs of Part 18 have remained the same since 1946.

Since then, however, vast technological advances have occurred. Semiconductors, integrated circuits, and digital systems have appeared. Many new devices operating at frequencies substantially higher than in the late 40's present new interference problems.

Consequently, the FCC has proposed overdue changes to Parts 15 and 18. One proposed change in Part 15 is the certification of restricted-radiation devices such as electronic (coin operated) games that use rf energy, rf switching supplies operating above 10 MHz, wireless intercoms, etc. Other devices will be added to the list as the need arises.

A real headache for the FCC is the TV game that can be connected to the antenna terminals of the owner's set. "These games are potentially as popular as CB sets," says Milton Mobley, chief engineer in charge of the FCC's testing laboratory in Maryland. "We've had more applications for TV game type approval in the second quarter of '76 than we had in the past four years ..."

A number of interference sources producing random broadband electrical noise can be just as disruptive to communications as the narrow band emitters, such as CB sets. As yet, these devices are unregulated by the Commission. However, complaints from these products have increased.

A New Repeater Era?

Can you imagine walking around town with an HT and talking to the world on 20 meters? Or talking to Japan when propagation conditions are mediocre? All that and *much* more may be possible if Docket 21033 goes into effect. The notice of inquiry and proposed rule making would profoundly shake up the existing system of repeater licensing and operation.

That bombshell was released early in January by the FCC. As the Commission puts it, "Our experience has demonstrated that amateur radio operators are fully capable of developing and operating complex systems of stations with a minimum of regulation by the Commission. We are aware of no compelling reason why amateurs wishing to operate repeater, auxiliary, control, or remotely controlled stations should continue to be required to obtain Commission permission before beginning such operation."

The FCC then goes on to propose that all repeater licenses be eliminated altogether. *Any* amateur would be allowed to set up a repeater *without* the need for FCC permission.

But that is not all. The docket proposes that deregulation of repeater stations continue with deletion of the requirement that all open repeaters be monitored by control stations in real time or be recorded. Logging requirements would be changed so that rather than authorized control points, the names and addresses of control operators would be listed in the log.

So what? That might create a bit more confusion on 2 meters. The biggest shock comes in paragraph 12 of 21033. Again, quoting the FCC, "It appears that many amateur operators seek greater flexibility in the choice of frequencies for repeater operation. We are therefore proposing to permit repeater operation on *all* frequencies allocated to the Amateur Radio Service, except 435 to 438 MHz." Completely unexpected, that part of 21033 seems to be the biggest surprise out of Washington in quite a while. The implications, should the docket be adopted, are enormous.

73 contacted several frequency coordinators and other amateurs and asked for their initial reactions to the proposal. The majority of answers were negative, ranging from mild dislike to utter consternation. In general, the feeling seems prevalent that near utter chaos will result from complete repeater deregulation. Those involved with frequency coordination were the most vehemently opposed, saying frequency coordination is difficult enough at the present time.

It's evident that with the ever-increasing headache of CB and the attendant enforcement and paperwork problems that are being created, the FCC is anxious to ease their workload in amateur areas. The paragraph about amateurs being able to operate with a minimum of regulation is one that all hams can be proud of. Coming from a government bureaucracy, it becomes even more amazing.

The problem is, with the number of hams increasing, how long can we continue our self-regulation? With increasing numbers come increasing problems. Witness "Repeater Appreciation Week" on the West Coast and the "Ohio RTTY War" (see *Briefs*). Suddenly, operators who feel they have a "right" to a frequency and increasing congestion on repeaters are creating bad feelings and hardening attitudes.

It seems that the FCC's proposal would create, if not chaos, a good bit of confusion and disorder on the ham bands. The FCC says that part 97.63 would be revised to "emphasize the two principles which have made possible the efficient operation of many amateur radio stations in relatively small spectrum space, namely, that a station using a frequency has first priority in such use over other stations and that all frequencies allocated to the Amateur Service are shared on a non-exclusive basis. It is presently the responsibility of amateur licensees to strike an appropriate balance between these principles to ensure the fair and efficient use of available spectrum." The existing rules say that if a repeater channel is being used for simplex operation, the control operator is not supposed to allow the repeater to be turned on. How often is this the case? The Commission further recognizes that increased congestion might result, and goes on to say that at the present time, they have no specific recommendations to make regarding coordination. They do, however, solicit comments in that area.

The appeal of a 2 meter to 15 meter repeater or any of the numerous possibilities is too great to dismiss. Perhaps a mandatory system of frequency coordination will have to be instituted. *73* is currently surveying the comparative success and failure of coordination. Look for a special report on the subject in next month's issue.

April 1 is the deadline for comments on Docket 21033. They may be sent to Federal Communications Commission, 1919 M St., NW, Washington DC 20554.

CB and the ARRL

A scenario has become clear regarding ham radio, CB, and the ARRL. Some clues from* X-MITTER, *Journal of the Penn Wireless Association, Bristol PA:

We are grateful for having had Chod Harris WB2CHO as our speaker at our twelfth annual awards banquet on the 13th November. Chod is an excellent speaker, and presented an important message.

Chod is running the newest ARRL department: Clubs and Training. His most important responsibility right now is assisting as best possible the recruitment and training of new amateurs — these times being the best ever for the expansion of amateur radio. He, presumably in concert with others of the HQ staff and the Directorate, obviously has studied at length the varied avenues possible, and is directing the League's major effort to presenting our story to those who have tried casual and hobby-type operating on the Citizens Service and have found it unsuitable for such use (as FCC intended).

His presentation to Penn Wireless touched only briefly on the training aspect, however. His message was that of top level cooperation between the two services, lumping them (correctly) as "personal communications" wherein one group has tremendous numbers and practically no expertise, and the other, with comparatively low numbers, has technical abilities fully in line with the state of the art. Personal communication in general having need of overpowering numbers and the ultimate in technical abilities, the combination should be irresistible while individually both could founder.

What are the situations to which this might apply? Many exist — they can be left to the imagination. Several were discussed at the banquet both in Chod's formal presentation and in the open discussions following. Local level legislation, for one. Tower ordinances are literally flying around the country; many are very poorly drawn. There is even some attempt to legislate RFI! RFI is an extreme problem. Our BCI and TVI problems of 10 and 20 years ago seemed bad at the time, but those of today are orders of greater magnitude. Emergency communications practices — they're always needed. Competition with other services, both domestic and international, is a continual problem, coming to a periodic head with the 1979 WARC.

All of these problem areas and more can be handled best with numbers (which CB can provide) and the ultimate in technical abilities (which we have). Thus, the times demand that we seek out the CB users to offer our complete cooperation. Why not the other way around? Because there is not (and likely will never be) any centralized CB organization in any way comparable to our ARRL and IARU. The service simply is not adaptable to any such centralization any more than there could be a central organization of telephone users. An ATT and an FCC, perhaps, but of users?

What is evolving is the stabilization of the two services. Those who would have radio for learning about electronics and radio will ultimately be licensed amateurs; those who need radio — for whom the wired telephone is insufficient — will be CB equipped. And probably this latter group will include most of the mobile portion of our population, for business communications are really desirable for most of us. The enforcement problem will never disappear, but it's conceivable that as the hobbyists leave the Citizens Service for amateur radio, the CB enforcement will become practical.

This is the goal which ARRL is aiming for. The tiny group in Newington can't do it alone. They can only help coordinate a flexible program and rely on us as scattered clubs and individual responsible amateurs to implement it. But the way Chod put it to us, it is not only mandatory to the long term welfare of amateur radio, but it's already started. The future of amateur radio looks good. Our 1976 facilities exceed anything imagined in 1956. It's predicted we won't need another 20 years to see equal advancement and expansion.

Updating WARC

Opposition to FCC WARC proposals for 15m and the lack of additional ham bands at 10, 18, and 24 MHz are prime ARRL reactions to docket 20271 (see Special Report, 73, February, 1977). Following is part of a letter to affiliated clubs and League Directors issued the week after FCC publication of the proposed US WARC position.

"We urge you to study this carefully and to file comments with FCC. This is one of the most important documents on amateur radio that you will see in this decade, and it is imperative that the Amateur Radio Service make its voice known in these proceedings.

"There are three broad areas where we believe comment will be beneficial. First, where we agree with the position taken by the Commission, we should comment favorably and reinforce their action. This is necessary because undoubtedly other services will be unhappy with some of the gains registered by the amateur service and will seek to have those positions modified. Thus, we must be sure to support the Commission in those actions they have taken in favor of the amateur service. For example, the FCC has proposed the creation of a new amateur band at 160-190 kHz, it has proposed an exclusive amateur band at 1800-1900 kHz and a shared amateur band from 1750-1800 kHz, it proposes the continuance of the 3500-4000 kHz band making 400 kHz exclusive in place of the present sharing arrangement, it proposes expanded bands at 6950-7300 and 13950-14400 kHz, and our bands at 28 MHz and the VHF/UHF are maintained. These are positive actions to comment on favorably.

"Second, we believe that adverse comment is required concerning the proposed change at 21 MHz. The Commission has shifted that amateur band from 21000-21450 to 20700-21200. Admittedly, this is a gain of 50 kHz, but it would come at the expense of considerable modification and replacement of existing amateur equipment. The Commission stated that the shift in the band was necessitated in order to accommodate certain requirements of the maritime mobile service. However, the League staff believes that with a slight rearrangement of the various allocations in the vicinity of 21 MHz, the martime mobile requirements can be met and the amateur bank 2100-21450 need not be shifted.

"Third, we believe that our original request for new bands at 10, 18 and 24 MHz was entirely justified, and has not been given adequate attention. In particular, a new band at 10 MHz, even a narrow one, would permit improved communication between amateurs in all parts of the world at those times when the maximum usable frequency does not reach 14 MHz. At the present time, such communications must be conducted at 7 MHz, a circumstance which requires the use of greater transmitter power because of increased absorption and interference from the Broadcast Service. New bands at 18 and 24 MHz would serve similar purposes."

At deadline, the word from Washington sources was 15m could be solved, but new ham bands at 10, 18, and 24 MHz seem unlikely. More next month.

Breaker, Breaker, Six...

A large volume of our mail continues to focus on theft . . . and here's one of the better ones, courtesy of the Minuteman Repeater Association Bulletin, Lexington MA. Jack W1DXQ and Murry K1GGP tell how an "MMRA Soft Sell," follow-up, and just plain cool help recover a stolen rig.

One afternoon in October, W1DXQ and K1GGP were in QSO during DXQ's "long" ride home from work. During our QSO, we heard a rather odd break station.

"Breaker six."

Our first thought was ignore him and he might go away.

"Breaker six."

Well, guess he won't go away; maybe we can scare him away. We stood by for the break station, and the conversation went like this:

Good Guy: Go ahead, breaker.

Bad Guy: Hey there, good buddy, is this channel six?

Good Guy: No sir, this is not channel six. You are operating on the two meter ham band. This is not the CB band. It appears that you don't know that you have a ham radio there.

Bad Guy: Oh, OK, good buddy, just doing some work on this here radio for a friend of mine. Trying to find out how this mobile telephone works.

Good Guy: Well, first of all, you do have a very good signal. However, you cannot operate unless you have a ham license. If you're working on the radio for a friend, he must be a ham and would do his own. If you or he thinks it's a CB radio, it must be a hot radio, and you must have a second class or better to do service work on CB equipment. By the way, what's your handle?

Bad Guy: Handle here is Rick. I didn't know about the license stuff.

Good Guy: Well, Rick, I would suggest that you cease operation of that equipment because you don't have a proper license. (Now for a big scare:) The Federal Communications Commission and other federal agencies frown on such activities. By the way, Rick, the handle here is Jack. You are giving us such a good signal, I wonder, what's your 10-20?

Bad Guy: OK, Jack, 10-20 here is Hanover.

K1GGP overriding "Bad Guy": Hey — I know of equipment that was stolen at the Hanover Mall.

Bad Guy continues: Well, thanks for the information, Jack. I had better get out of here now.

Good Guy: OK, Rick, it is a good idea that you do that. You will save yourself a lot of grief. The repeater would be shut off anyway if you continued to transmit. I'd like to give you more information on this subject, Rick. Do you have a telephone number that I can reach you at?

Bad Guy: Ya, sure, Jack. You can get me at 826-XXXX; got it?

Good Guy: OK, Fine, Rick. I have it and I'll give you a call later.

Well, the "Bad Guy" went away, and Murry and I carried on for a short time, making few comments on the incident.

After I arrived at home, I thought, what the heck, I'll give the guy a call. I know it's a phony number. He was a dummy, but the odds are that he wouldn't be stupid enough to give me a valid telephone number. I called and sure enough, he now qualified as "dummy of the year."

Good Guy: Hi Rick, this is Jack.

Bad Guy: Hi Jack, glad you called. (Gads, super dummy!)

Well, at least he told the truth about the telephone number . . .

Good Guy: I think you should get rid of that radio, as your friend appears to be the owner of a hot radio. What is your friend's name?

Bad Guy: Well, he is not my friend; he is a friend of a friend. I don't know his name.

Good Guy: Well, Rick, I would suggest that you get his name, or at least his plate number and a good description. When the FCC makes their investigation, they won't accept answers like that. (There — that line of bull should throw the fear of God into him — last we'll ever hear him on two meters.)

Bad Guy: OK, Jack, I'll give it back; he is getting me in trouble.

Good Guy: Well, Rick, you just tell the truth when the investigation comes about and you might not be in such trouble.

After the telephone conversation, I figured that just about all that could be done, had been done. To present such information to a local police department, or even the FCC, would be a waste of everyone's time. No real facts or names. Just a telephone number. During both the radio conversation and telephone conversation, the "Bad Guy" did mention that the radio was a Heathkit. I thought of the many rigs that had been stolen in the area, but I had knowledge of only one "Grief-Kit." I recalled that WA1QPL (Dave) had a Heath stolen several months prior. Murry verified that fact, but the chances of this being Dave's rig was a million to one shot.

With the 07/67 grapevine at work, Dave gave me a call after hearing of the incident. He mentioned his stolen rig taken eight months prior from his car in Milton. Well, as far as I was concerned, a Hanover thief would not go to Milton to steal a radio. Make odds now two million to one. Dave was quite interested in a follow-up to the Hanover police. I attempted to soften the blow. I have been through local police and, in most cases, they are too busy to be bothered, or in some cases, could care less. It appears I was wrong. Dave contacted Hanover and gave them what information he

CONTESTS

SOUTH DAKOTA STATE QSO PARTY

Starts: 0000 GMT March 13
Ends: 2359 GMT March 14

The contest is sponsored by the Prairie Dog Amateur Radio Club. The same station can be worked on different bands, modes, and counties for multipliers.

EXCHANGE:

SD stations give RS(T) and county; others send RS(T) and state, province, or country. No SD to SD contacts!

FREQUENCIES:

Phone — 1.975, 3.920, 7.230, 14.280, 21.380, 28.510.

CW — 70 kHz up from bottom.

Novices — middle of band.

SCORING:

SD stations multiply number of contacts times number of states, provinces, and countries. Others multiply number of contacts (with SDs) times number of counties.

ENTRIES:

Certificates to each section. Send logs by April 1st to: WB0EVQ, Box 493, Springfield SD 57062.

CQ WORLDWIDE WPX SSB CONTEST

Starts: 0000 GMT Saturday, March 26
Ends: 2400 GMT Sunday, March 27

Only 30 hours of the 48 hour contest period permitted for single operator stations. The 18 hours off may be taken in up to 5 periods during the contest, but must be clearly indicated in the log. Multioperator stations may operate the entire 48 hours. All bands, 1.8 to 28 MHz, may be used, but all QSOs must be 2xSSB only.

ENTRY CLASSES:

Single operator, all band or single band; multi-operator (all band only), single or multi-transmitter; multi-operator, multi-transmitter only allowed one signal per band.

EXCHANGE:

RS and 3 digit progressive QSO number starting at 001; use 4 digit number over 1000; multi-transmitter stations use separate numbers for each band.

POINTS:

QSOs with stations on different continent — 3 points on 14 to 28 MHz, 6 points on 7 to 1.8 MHz. Contacts between North American countries (not your own) count 2 points on 14 to 28 MHz, 4 points on 1.8 to 7 MHz. Contacts between stations in the same continent but not in same country count 1 point on 14 to 28 MHz, 2 points on 1.8 to 7 MHz. Contacts between stations in the same country count only for multipliers, not for QSO points.

MULTIPLIER:

The multiplier is the total number of different prefixes worked regardless of band. Each prefix may be counted only once.

SCORING:

Single op, all band and multi-operated stations — total number of QSO points from all bands times the total multiplier. Single op, single band — total number of QSO points from that band times the multiplier. NOTE: A station may be worked once on each band for QSO points, but the prefix multiplier is only counted once.

AWARDS:

Certificates will be awarded in each category in each country, and each call area in US, Canada, and Australia. Other special awards and trophies will be awarded as listed in *CQ Magazine.* To be eligible for awards, single operator stations must work a minimum of 12 hours; multi-operator stations must work a minimum of 24 hours.

LOGS:

Show all times in GMT; use a separate sheet for each band. Prefix multipliers should be entered only the first time they are contacted. Logs should be checked for duplicate QSOs and prefix multipliers. It is recommended that you use a prefix check sheet and include it with your entry. Each entry must be accompanied by a summary sheet listing all scoring information, category, and your name and mailing address in block letters. Also, a signed declaration that all contest rules and regulations for amateur radio in your country have been observed should be included. Official logs and summary sheets are available from *CQ Magazine.* Send a large self-addressed envelope with sufficient return postage or IRCs to: CQ WW WPX SSB Contest Committee, 14 Vandeventer Avenue, Port Washington, LI, NY 11050. All entries should be postmarked no later than May 1 and addressed to the address shown above. The deadlines will be made more flexible in rare isolated areas.

Please check the January issue of CQ Magazine *for complete rules and changes made at the last minute.*

BARTG SPRING RTTY CONTEST

Starts: 0200 GMT Saturday, March 26
Ends: 0200 GMT Monday, March 28

Only 30 hours of the total 48 hour contest period may be operated. The 18 hour rest period can be taken at any time, but off periods may not be less than 3 hours at a time. Times on and off the air must be summarized on the log and score sheets. There will be separate categories for multi-operator and SWLs. Use all amateur bands from 3.5 to 28 MHz. Stations may not be contacted more than once on any one band. In addition to the ARRL country list, each W/K and VE/VO call area will be counted as a separate country.

EXCHANGE:

Time in GMT, must be a full 4 figure group — use of "same" or "same as yours" will not be permitted. RST and message number. Message number must consist of a 3 figure group starting with 001 for the first contact.

POINTS:

All 2-way RTTY contacts with stations within one's own country will count 2 points. All 2-way RTTY contacts with stations outside one's own country will count 10 points. All stations will receive a bonus of 200 points per country worked including their own. NOTE: Any one country may be counted again if worked on another band, but continents are counted only once.

SCORING:

The total score is the sum of (the 2-way exchange points times the number of countries worked) plus (the number of countries worked times the country bonus points times the number of continents).

LOGS & SCORE SHEETS:

Use one log sheet for each band and indicate any rest periods. Logs must contain: date and time in GMT, callsign of station worked, RST report and message number sent, RST report and message number received, and exchange points claimed. The judges' decision will be final. Send contest logs to: Ted Double G8CDW, 89 Linden Gardens, Enfield, Middlesex, England EN1 4DX.

AWARDS:

Certificates will be awarded to the leading stations in each class and to the top stations in each continent and each W/K VE/VO call area. The final positions in the Results Table will be valid for entry in the "World Champion of RTTY" Championship.

If any contestant contacts 25 or more different countries (W/K VE/VO call areas do not count as separate countries for award) on 2-way RTTY during this contest, a claim may be made for the QUARTER CENTURY AWARD issued by the British Amateur Radio Teleprinter Group and for which a charge of $2.00 or 8 IRCs is made. Make your claim at the same time as you send in a contest log. Holders of existing QCA Awards will automatically have any new additional countries added to their records.

If any contestant contacts stations on 2-way RTTY with all six continents and the BARTG Contest Manager receives contest logs from the operators in those six continents, a claim may be made for the WAC Award issued by the RTTY Journal. The necessary information will be sent on to the RTTY Journal who will issue the WAC Award free of charge.

WISCONSIN STATE QSO PARTY

Starts: 0000 GMT Sunday, April 4, 1977
Ends: 0000 GMT Monday April 5, 1977

This annual event is jointly sponsored this year by the Neenah-Menasha Amateur Radio Club and the Yellow Thunder Amateur Radio Club. Phone and CW are considered separate bands. The same station may be worked once each band, county and mode. Wisconsin stations may work other Wisconsin stations for QSO and multiplier credit. No contacts can be counted if made on Wisconsin nets while in session or if made through repeaters except for OSCAR. Multicounty portable/mobile operations can be worked in each county they operate from.

LETTERS

CAN SOMETHING BE DONE?

Gentlemen:

I am writing this letter to inform you and fellow amateurs of my recent experiences with and the apparent "fraud" of Trigger Electronics of 7361 North Avenue, River Forest, Illinois 60305.

Enclosed you will find a copy of the letter I have sent to the Illinois Attorney General's Office concerning Mr. Treger's so-called business. I hope you will make this information available for those who read your publication. Hopefully, this will stop many people from making the mistake of placing an order with Trigger Electronics, as I have done.

Anyone interested in information about Trigger Electronics or the appearance of the store itself in River Forest, please feel free to contact me.

David B. Hasenick WD8BNS
8369 Ferris Road
Springport MI 49284
Phone: (517) 857-2385

On October 8, 1976, I ordered from Trigger Electronics, River Forest, Illinois, merchandise amounting to $177.93 by a mail order. I sent a postal money order in like amount to pay in full the amount of my order, copy attached of postal money order #21602081193.

After much time had gone by and I had not even received an acknowledgement of my order, I made several telephone calls to Trigger to see what had happened to my order. Some of the phone calls were by date and amount as follows: October 27, $1.60; November 3, $1.02; November 9, $1.31; November 17, $1.42; November 27, $1.08. At those times I was told that the order was still being processed, but that they had no record of any orders being sent until 30 days after the order was received there. This didn't exactly make sense, but it was their reply.

During this time, a small amount of merchandise from my order was received by me in the amount of $20.41, leaving the balance of $157.52 for a large antenna.

After many of these fruitless telephone calls, we drove to Chicago on December 8, 1976, to Trigger Electronics. The woman that met us in the front office gave the same story as we had received over the phone – that there was no shipping department there, that it was elsewhere and she did not know the location or telephone number of such a department, etc. In looking over in back of the office area, it looked like what shipping was done was one package with dust on it that looked like a "front" and had been lying there for ages waiting to be "shipped." There were stacks of orders lying around with envelopes open and papers still in envelopes. She then told us that no one else was there, but we saw others in the back and asked about this. We were told that everyone was indeed out to lunch and might not be back all afternoon when we pressed her. We then told her we would wait until they arrived. When we persisted, Mrs. Treger came running out from in back screaming that she would call the police if we didn't leave the premises right away. She made this phone call (or what was supposed to be a phone call) to the police, but we waited and no one showed up from this "call." We told her that we were there to settle this account and that we did not drive 200 miles one way for nothing. Finally one of us left to call the police ourselves while the other stayed. Then Mr. Treger showed up from hiding in back and said he was going to beat me up if I didn't leave. He was screaming with fists clenched and would not begin to talk any business, just told me to get out or else he would get me out with a shotgun. When I did not leave, then he did come out with a gun. I did depart and went to the River Forest police station. We went over the entire situation with Sgt. George Straugh, who said his hands were tied unless Treger actually assaulted or shot us. They were as helpful as they could be and suggested we write your office with complete details on this experience.

Now how can any business be left to operate when they only pocket the money and do not ship ordered and paid merchandise? Where are the laws that protect the individual from losses like this? How many people must they cheat and steal from before something can be done?

David Hasenick WD8BNS

BOYCOTT TRIGGER

Let me introduce you to one of the most efficient employees I have yet to encounter. This hard-working and dedicated person is – the TRIGGER TELEPHONE LADY!

As I had ordered an antenna from Trigger Electronics in July and was still awaiting its arrival in November, I called to ask why. That is when I first met the Trigger Telephone Lady! I could almost see her smile sweetly as she promised immediate action.

During that and four subsequent phone calls (so far), the Trigger Telephone Lady has compiled the following exemplary record:

She has succeeded in forgetting all previous calls, even when two were made the same day.

She has managed to place me on hold an average of twice per call (at long distance rates this is a rather convincing argument).

She has apparently lost every message she took as I have never been contacted by Trigger on the missing antenna.

Through all of this faithful service, she preferred no public recognition for her excellent work and consistently refused to give her name, job title, or employee number.

She has remained utterly faithful to her employer throughout, effectively insulating Trigger Electronics from all complaints so that they might continue to perform their dastardly deeds unhampered by the outraged squawks and protests of their victims. All Hail to the Trigger Telephone Lady!

Gary S. Breschini WB6NCK
Salinas CA

P.S. How about including "Boycott Trigger Electronics" on all QSL cards being sent to Novices, that they too may join in the praise of these turkeys?

FISHY

Just a short note to you regarding the letter in your column about IL *vs* Trigger. I have sent the Attorney General's office my incident with Trigger, that Trigger must have my check in their hands, cleared by the bank, before I could come in the store to pick up any merchandise, if they had it in stock. Sounds fishy, huh?

Thank you for your kind attention.

Art Surges
Evergreen Park IL

P.S. I took my business elsewhere.

IRKED

As a subscriber to your mag, I thought that I would write you about one of your 1975 articles.

This is in reference to the Levy Associates ad, this company formerly of Temple City CA, now of 1037 E. Lemon Ave., Monrovia CA 91016. For approximately $110, I purchased a ÷10 and ÷100 prescaler. This did not work with my MICRO Z FM 36 counter; however, I assumed that the counter's sensitivity was low. So then I purchased a Hewlett-Packard 5381A counter and a Davis (Tonawanda NY) scaler. This combination works perfectly.

I then sent my prescaler back to Stanley Levy WB6SQU on 4 Oct., 76, at their request. Early this year I received the scaler and he said they had a hard time getting the ÷100 IC; it is a Plessey. Believe this is an English make; he also said they have discontinued manufacturing this scaler due to trouble getting this part.

Well, at any rate, not sure if they ever did replace the IC. It doesn't work anyway, so have resigned myself to *never* ordering any gear from a small manufacturer, though I will say I am happy with the way the Davis divider operates.

Always liked to patronize small companies – but never again.

Have about $10,000 of gear here, so can afford the loss, but it sure irks me.

Larry Briggs W3MSN
Oxon Hill MD

Don't prejudge all small companies – that's where the big ones come from. – Ed.

HIGHLY RECOMMENDED

During this day and time when there seems to be so much emphasis on the negative, it is nice to get service from one of your advertisers, Communications Specialists in Brea, Calif., like I did. I ordered their ME-3 on Monday and I had it the next Monday. This is real VIP treatment. No waiting for my check to clear the banks and they sent my ME-3 UPS Blue Label Express, all prepaid. You can bet that I will highly recommend them to my friends. And the unit works A-1.

Madison TN

ARRL ON TOP

In Dec., 1976, *QST*, page 38, recent equipment (HAL's FYO keyer paddle) is described. When I attempted to order one, I discovered that HAL is no longer making them – ARRL is really on top of things. I became angry and decided to see if I could make one myself. It proved much easier than I had imagined, and was made entirely from the junk box. It required only simple hand tools such as a hacksaw and a small round file. Mounted on a walnut base, it is also good-looking.

Every CW op to whom I have mentioned the project has been interested, and several have sent an SASE for a sketch. And so I ask if you might be interested in an article, "The Poor Man's FYO," with photos and sketches, etc.

THE GENTEEL HALF

I'm sure you'll find this one interesting from the "genteel" half of amateur radio.

Christine Boniakowski WA2KOU
Neptune NJ

Editor – *QST*
American Radio Relay League
225 Main Street
Newington CT 06111

Dear Sir:

I have been an amateur radio operator for approximately four years and absolutely love being a part of a

"man's world." I enjoy taking part in contests and am quite surprised by the different reactions I get from various operators when I am on the air.

However, it has come to my attention in the last few contests that there must be some guidelines established regarding the use of the national calling frequency of 146.52 MHz. The contests I am specifically referring to are the recent June, 1976, and January, 1977, VHF Sweepstakes.

In my opinion, it's not very fair for people to monopolize the national calling frequency for solely high power contest use since VHF Sweepstakes are intended to test both equipment and operating skill. However, it is quite obvious that there are many of us who are fortunate enough to have top-of-the-line equipment, including big arrays and kilowatts. These are fine at the low end of the band but not on 146.52.

In addition, since when have the FCC regulations been changed to allow a reverb on the air? I did not know that hams were in the radio broadcasting business.

I would like to suggest that 146.52 and all FM frequencies above 146 MHz remain contest-free and that the ARRL contest advisory committee look into the matter of suggesting alternate FM simplex frequencies for use during contests. Why should the FM bands be monopolized by a few who are inconsiderate and cannot leave the simplex bands alone for the purpose they were intended for — low power, mobile intra-community communications and public service.

I have been informed that the ARRL has refrained from publishing letters that tend to question its activities, of which the VHF Sweepstakes are a part, but it will be interesting to see how much attention a female rocking a male boat will receive.

Thank you for your consideration in this matter. I hope that there will be changes made in the near future to safeguard the FM bands from being hoarded by the "big guns."

Christine Boniakowski WA2KOU
Neptune NJ

She said it. — Ed.

RETROSTEP

San Antonio, which was among the earliest proponents of the Texas Band Plan for VHF/UHF FM (which was later adopted almost en toto by ARRL as a National Plan), joins the Bicentennial Celebration by virtue of a retrostep which sets orderly spectrum utilization back 20 years, if not the full 200.

South Texas first provided the English language with the word "maverick" during the mid-1800's when rancher Samuel A. Maverick allowed his unbranded cattle to roam the open range.

To top Sam Maverick's independence required considerable effort, but alas, it has been done. San Antonio now has a maverick to top all mavericks: WR5AFF/5 (no challengers please). This ill-conceived maverick repeater, licensed to Robert J. Sarvis WB5CIT, has its input on 146.39 MHz and output at 147.51 MHz (a designated simplex channel). With a rather unique spacing of 1120 kHz, this anachronistic machine conforms to accepted practice only in that it operates with low in/high out, and uses a 30 kHz channel for its output. Whether or not this was due to some oversight, or confusion caused by the choice of 146.39 MHz, which isn't even a half channel, could not be determined.

Please consider the creation of a Maverick of the Year Award to properly honor the contemptuous disregard for established order which characterizes such operations as this. The efforts of thousands of dedicated amateurs to voluntarily regulate themselves and promote orderly growth and spectrum usage appear wasted on our barbaric brethren.

Robert G. Wheaton W5PKK
San Antonio TX

GET OFF OUR BUTTS

After three unsuccessful tries of obtaining publication in QST (you remember, that's the organization "devoted entirely to amateur radio" — I understand that slogan will be mounted on the new $800,000 wing of ARRL Headquarters, Hi Hi), I thought after recently subscribing to *73 Magazine* and liking what I saw, I would appeal to you.

My message to our wonderful ham fraternity is this: Let's get off our butts and devote the same amount of energy towards publicizing and promoting amateur radio as we do denouncing the CBers and their band. Recently coming up from the ranks myself and passing my General theory, I do not believe the majority of amateurs are aware of what's going on in today's advanced CB market. In particular, I am talking about the so-called SSB HFers who operate between channel 23 and the ten meter Novice band. This group of bootleggers numbers over 70,000 with their own published callbooks and specialized illegal callsigns. Sure, a lot of these interested shortwave radio enthusiasts are running amateur equipment. It is easily available and the distributors and manufacturers of this equipment see the money in this market and of course are not going to establish any rules or regulations to prohibit sales. All we need to do is grab the "cream of the crop" from these ranks and talk about, demonstrate, and third party these fellows right into ham radio. The old tightwad image of the average ham radio operator is changing. These fellows already have been practicing Morse code, know about propagation, and have erected everything from tribanders to inverted vees. Still a nonbeliever?

Take a look at the gear confiscated in recent raids in the Baltimore area (*73*, January, 1977, page 12 — $65,000 worth), and that's just a drop in the bucket compared to other populated areas.

My point is this: For years we have been searching through our local clubs, etc., for people interested in getting into amateur radio, people who have no idea at the beginning what shortwave radio is all about and become easily turned off at the expense of getting into many areas of ham radio. We are looking in the wrong places. Get out of those department store and shopping center exhibitions and try going to some of the CB coffee and breakfast breaks on Sunday mornings. In my area, the hams meet at one end of the restaurant and the CBers in the other. Ridiculous, isn't it? Let's get together.

Mike Stone WB0QCD
Durant IA

MORE Z-80

I'd like to add my thoughts to yours concerning the Z-80 CPU chip in I/O Editorial in the December, '76 issue of *73 Magazine*.

Those of us who already own a 8080 based microcomputer can hardly be expected to junk a perfectly good CPU card and run right out and buy a Z-80 CPU! Remember that for many of us it was all we could do to get that 8080 based machine into the house — past all of the cold stares of our spouses, our friends, and our creditors.

Obviously, the Z-80 chip is intended for the "unlucky" souls that have yet to buy their first computer (that includes me). I am enthused about the Z-80 chip — precisely because it is advertised to execute 8080 programs without reprogramming! Furthermore, there are numerous new instructions that would appear to be valuable for a general purpose computer to have. Thus this Z-80 chip appears to give me the best of both worlds! Easier implementation electronically only sweetens the deal.

In my year of studying all of the uP oriented articles in *73* (and *Byte* and anything else I could get), I had largely ignored the 6800, 6501, F8, SC/MP, and all the rest, because I sensed that right or wrong, the largest number of active and unselfish programmers were probably on the 8080 bandwagon. Had the Z-80 chip not come along, I would have bought an 8080 chip based machine. Now that the Z-80 is here, that is what I'll buy, on the basis that it is "upward compatible" with the 8080 chip.

I expect to use those fancy new Z-80 instructions only when writing programs for new applications, for which satisfactory 8080 programs were not available.

Concisely, when I write programs for the *Kilobaud Software Library*, I expect that they will be in Z-80 code, but I expect that I will also submit an 8080 version (to fatten my royalty checks?) that will be virtually the same program except that each of the Z-80 only instructions would be replaced by a CALL to a subroutine that effectively emulates the replaced Z-80 instruction in 8080 code.

Waterville ME

A REAL STATION

Along with my sub extension, I thought I would send along a minor gripe. It is about all those pictures of shacks and operating benches, desks, etc. I don't know how those people can even get on the air with those setups! Don't they know that clip leads, wires, and cables are essential to normal operation? Also, where else can you hang schematics, girlie pictures, calendars, logbook — to mention only a few. I am enclosing a photo of a *real* station. As you can readily see, everything is within easy reach — no hunting around for stuff. Band changes are a snap — merely move clip lead(s) from here to there. I didn't include a photo of the repair and building bench, as it is a mess.

But seriously, you have a fine magazine. It is the only one (of four originally) to which I still subscribe. The others seemed to aim their articles toward the more (than me at least) affluent amateurs.

Keep up the good work.

Steve Welsh WB9MLM serving as net control for March of Dimes Bike-a-thon from his hospital bed.

NEVER SAY DIE!

Here's a picture that the XYL took, and I think it's a good demonstration of the fact that hams are crazy enough to operate anywhere! Members of the Twin Ports Two Meter Club of Duluth, Minnesota, and Superior, Wisconsin, recently ran checkpoint communications for the March of Dimes Bike-a-thon. I had planned to help, but was hospitalized with an acute asthma attack. But between sessions on the respirator, I served as net control station, operating through WRØAIM, Duluth's 34/94 repeater. I was able to access it easily with my HR2A and a ¼ wave. Never say die!

Steve Welsh WB9MLM
Superior WI

LLOYD AND IRIS

We have just finished another successful DXpedition at VP2EEQ, Anguilla. Some 8,000 QSOs were made with amateurs in 123 countries. Operation was on 28 through 3.5 MHz, with very heavy concentration on 3.5 MHz.

Anguilla was different from our other Caribbean stops for two main reasons. There is no town or city in Anguilla, at least not in the normal sense. There are some stores, banks, etc., but they are widely separated and not in one downtown area. The other difference is that there is no central electric power system. Most people, including ourselves, have to obtain their electric power from individual electric generators. Our generator broke down just before we left and our stay in Anguilla was, therefore, cut short by a few days.

The people of Anguilla are very friendly and helpful. A radio amateur license is obtainable immediately, upon payment of $25 US. The country is relatively flat, which is a welcome change from most of the nearby countries which are mountainous, making it difficult to find a good radio site.

We ended 1976 with more than 70,000 QSOs operating from nine different DX countries.

KV4AA, a YASME Director and former President of the YASME Foundation (QSLs via YASME after 1 January 1977), finished the year with over 35,000 QSOs, all from AJ3AA.

It is most likely that every serious DXer in the world made at least one QSO with a YASME station in 1976. We hope that 1977 will be as good.

Lloyd Colvin W6KG
Iris Colvin W6QL
Anguilla

NEED VE6?

I got a hold of a couple issues of *73* and have already sent my subscription for 3 yrs. This VE6 thinks you have a great mag. Your editorials are great. I would like to see some beginner's basics on microprocessors.

Also, any W/K stations looking for VE6, I am on most afternoons on 14.300 or 21.300 and would be glad to contact.

Keep up the good work, Wayne. See you at Orlando Hamfest.

Arnie N. Brown VE6ARD
Calgary, Alberta Canada

ATTICA

At present I'm doing a stretch here in Attica Prison and the only way I can keep up with what's going on in the ham world is through reading. Seeing that I can't pop over to the local radio emporium for my monthly copy of *73* anymore, I finally have to subscribe. In a few days you'll be getting my money order for $9.00 a one year subscription. If the price has gone up, please let me know and I'll send the balance pronto. In the meantime please start with the Jan. 77 issue.

I'd subscribe for longer but I'm hoping to win my appeal. But if I should lose what's your rate for 15 years?

Two questions maybe you can help me with. Know anybody who would like to buy a used Drake TR-22C in good shape, except for the antenna which was broken while being chased by the cops? Plenty of crystals and cheap. Also my trusty ole Galaxy III, ac power supply, VOX, etc. Will sell all my gear cheap because I need money for my lawyer. And do you know any ham who would like to write a ex-ham in prison? A YL would be great! But I won't be fussy.

Looking forward to reading *73* again.

Peter Neenos

Attica NY 14011

NEED BY?

You can say "I told you so!" So far I have run into brick walls on operating privileges. Most people don't know what I'm talking about, or act like it. One guy around my age (43) said his buddy was one "before liberation" (1949) up in Tiensen, about 60 km north of here. In the larger cities, I have been told, they let middle school age (12-15) children build and operate short-range radio transmitters and receivers (short-range = 100 feet).

I have a S/W receiver and can get CW on it but the only ham band it covers is 80m. So far I have not heard any K or W stations. Out of 13 Americans here, one is K5KNL, Fred from Texas. He lives on the top (3rd) floor and has an "outdoor" antenna on the roof. He can get 20 and 15 occasionally. We are straight west and a little south of Pyong Yang, N. Korea, inland of the Pohai (Wide Sea) on North China's east coast.

I haven't given up, but the chain of command to do anything around here staggers the imagination. Tsang Chou, with a population of 170,000 (and they each have a bicycle!!) is classed a "rural town" and doesn't rate much attention. I wrote Peking about a license, but so far no answer.

Anyway . . . much success in the coming year. If anything interesting develops I'll let you know.

China

HARD KNOCKS

I am writing this letter in the hope that I may be able to save someone else a lot of pain and suffering.

I learned my lesson the hard way!

Whenever climbing a tower to do any work, BE SURE TO USE A PROPER SAFETY BELT, or *don't* go up!

On 7 June 75, I was standing on top of the top section of a 3 section crank-up tower which we thought was completely lowered. Because of some confusion, the safety belt I was planning to use didn't show up that day. I figured I would be able to stand on top and wrap my left arm around the six foot mast extending above the top while with my right hand install a two meter antenna on top of the mast. Just as I was about to install the antenna, the tower section I was standing on dropped two feet suddenly. I lost my grip and fell off, about twenty feet down to the ground. Luckily, I landed rather erect with my knees bent slightly, which helped to break the fall, and I went down hard right on my rear and rolled back onto my back in excruciating pain. An ambulance was called and arrived about three minutes later, although it seemed like an eternity due to the intense pain I was in.

After the ambulance ride to the hospital, which was very painful because every little bump in the road sent shots of pain through my body, I was treated in Emergency and X-rayed to find out the extent of injury.

I suffered a hairline fracture of the lumbar number one vertebra, or in other words, a broken back.

I have now been in bed for 22 days and shortly will be getting a plaster body cast which will run from just below my waist to my armpits, which I will have to wear for 8 to 10 weeks. Not very pleasant during the summer; however, as temperatures in Vancouver rarely exceed 80°C, it might not be too bad.

I figure I was quite lucky in that there was no lateral shift in the fracture and no spinal cord damage, so I will suffer no paralysis.

I am still fairly young (29) and was in good physical shape when the accident happened; otherwise, I might have been permanently crippled.

I expect to be released from hospital in about a week.

In a few months I will be able to climb towers again, but NEVER WITHOUT A PROPER SAFETY BELT, as anything can happen.

I hope you print this so that others can learn from my error and misfortune and avoid injury.

Matthew T. Lewis VE7CHI
Vancouver, B.C., Canada

DON'T PUT CBers DOWN!

This is in reference to the letter published in your Holiday 76 edition of *73* by Carol G. Sakowski about CBs and CBers. Granted, Citizens Band is not the finest radio service in the world, but I was quite disturbed by Ms.(?) Sakowski's statement, "Anything that 6 and 10 year old kids can do, you can do, right?" True. But then take a quick look at ham. Anyone, regardless of age, can obtain a ham ticket through a simple multiple choice and Morse code test. There are children on your frequencies too.

I feel it is time that people stop putting down CBers! Face it – where would ham be without CB? There goes a good deal of electronic components, and, by the way, where do all the Novices come from? *CB*! Another thing – Ms. Sakowski does not seem to have any call letters. All of that from a non-ham?

I have been into CB for exactly one year. I am an avid SWL, and am one wpm from my Novice. However, even after I become well into amateur radio, I am not going to forget my many friends on 11 meters. CB may be crowded, ridden with illegalities, and not very efficient, but there are plenty of would-be hams on 27 MHz who are trying to clean up the channels of flakes. We are not *all* the typical "10-4 Good Buddy" media CBers.

I am proud of my CB call letters!! Do not put CBers down if you want some new hams!

Jim Cullen WAE2NR
Succasunna NJ

SOMEDAY . . .

This letter comes not from a ham, but from a long-time would-be ham. I just wanted to let you know that if I ever make it, you'll get a large share of the credit (or blame). For something like 15 years I've wanted to get into amateur radio. For 14 years, I was convinced that I could never learn the code. Now I've got your tapes and everything seems possible. Not easy — just possible.

I've also got the license guide books you publish and find them straightforward and logical. That's more than I can say for some of the things put out by the ARRL. Right now I'm trying to learn some of the basics through the Heathkit Continuing Education series. While I'm speaking from a position of ignorance, you might want to consider telling your readers about this series. Heathkit seems to have put together a winner.

You are to be congratulated for your efforts to bring CB people into the ranks of ham radio. While there are some crazies on that band (I tune up there and listen from time to time), there are also some very interested and dedicated people. These are the ones who would be tremendous as amateurs. I figure the crazies wouldn't have the patience to learn what they have to know to pass the tests, so, even if you get their attention, they probably still pose no threat.

Congrats, again, for getting into the home computer field. It is my feeling that within the next 5 years or so there will be a home computer system with adequate software to appeal to the average homebuyer. The fact that the hobby electronics magazines have nearly all added computer sections recently shows just how far ahead of the pack *73* really is.

So, thank you, Wayne, for keeping me on the track. Between the rigors of starting a new business and the time required by continuing to go to college, I still find some time to study radio theory. Someday . . .

William F. Blinn
Worthington OH

TOYS OF THE PEOPLE?

I want to send this note for what it is worth.

I am a ham who was a CB nut at one time before they became the toys of people who seem to need something to convey their silly talk over.

I have always wanted to work with radio but never had the chance . . . CB radio got me interested. I believe there are a lot of CB men like me who are in earnest about radio and doing it right. I do not believe, however, we should try so hard to get them. If they are in earnest, they will seek it out.

Above all, we should not let down the rules to let them in. I have had one heck of a time passing the tests, and for all those who told me "there's nothing to it," I can only say "speak for yourselves." But I will also say that now that I have my ticket, it was worth every bit of it. And it means something to me to have done the work.

I, too, thought CW was nuts before I learned it, because I didn't want to spend the time learning it. Now I can see its value and fun.

The best drawing power the ham has is his dedicated interest and knowledge of radio and communications. Most of my old CB friends have no idea what I have learned getting my ticket, but I have found they all hold a special respect in the fact that I am a ham. And frankly, I tell them if they want to get serious about radio, this is the route to take. But until they are serious, they're not ready for us and we're not ready for them.

I cannot help but believe that the FCC and others in power in this matter hold a respect for what the ham world has become and contributed all these past years.

I for one am very proud to be a ham and thank all those who have gone before me in making it what it is today.

Thank you for your time . . . just must speak out.

Clinton J. Reser
New Strawn KS

SEARS AND 2M

It was with great distress that I observed a two meter transceiver on page 967 of the Spring/Summer 1977 Sears catalog. I hope you and *73 Magazine* will take an immediate stand and make a strong statement to both Sears and the FCC. I strongly feel that the open availability of CB equipment through mail order catalogs such as this with no requirement or proof of licensure has added to the number of unlicensed operators on CB today.

I sincerely hope that rapid action will be taken to eliminate the unlicensed non-ham from acquiring a two meter rig, complete with crystals, antenna, and instructions on ham procedures. We have been very lucky in the past to prevent violation of the ham bands and I hope we will be able to nip this in the bud before two meters becomes another eleven meters.

George H. Stokes, Jr. WA4MZL
Mobile AL

We're on the case! Check out the Montgomery Ward story in Briefs. — Ed.

THE LUNATIC FRINGE

The following is going to be difficult to believe unless you have been on the Bicentennial Net for the past several months. Many derogatory comments are made about CBers, but what difference is there when licensed amateurs cause deliberate interference in the following ways: jamming with carriers of up to 30 minutes and more, profanity, obscenities and indecent language (by definition), amateurs with high powered linears that move as close to the net as possible and refuse to move when tactfully asked to do so, whistling, blowing, tapping, and groaning into the microphone, playing a radio and transmitting a phone patch signal deliberately on net frequency. Tuning up on net frequency was always done without any regard or consideration for fellow amateurs — this appears to be entirely acceptable for many amateurs at any time. CBers discourteous???

All of the above did not dampen our spirits; however, there was one thing that was learned very quickly and that was not to acknowledge this type of interference. It is like the obscene phone call — leave them alone and they will go away.

The fellows acting as net control certainly deserve a lot of praise for their patience in keeping the net operational. One bright spot to all of this was the amateur who checked into the net from Kentucky and said he would accept a collect call from any part of the country to get on the air at any time for his state. That is *truly* the Spirit of '76.

Eagan MN

The lunatic fringe lives. — Ed.

OPPOSING VIEWPOINTS

Thought you'd be interested in the enclosed clipping from *Computerworld*, regarding a radio program for ham-computer buffs.

In your January "Letters" column, you published a letter from AA7NEV, who didn't know what kind of time "PMEDT" stood for. Tell him it means afternoon or evening, Eastern Daylight Savings Time!

Your magazines, particularly the editorials, are always stimulating, generally thoughtful, and frequently controversial! Although your readers naturally don't agree with your points of view all the time, we gotta admit one thing: You offer, in the columns of your magazine, an opportunity for opposing viewpoints to be presented — a real rarity these days.

I only wish that all your reader-writers would use a little more courtesy in some of their comments, since the opportunity to present our views is a privilege *73* is granting to us, and not a right which we should demand and abuse.

Hang in there, Wayne!

Bill Houghtaling
Raleigh NC

You're kidding! If it's courtesy you want, read the letters in QST. Don't bother looking here. — Ed.

Hobbyists in Boston Getting Radio Show

CAMBRIDGE, Mass. — Computer hobbyists will take to the airwaves with their very own radio show beginning Jan. 22.

Believed to be the first radio series of its kind, "The Computer Program" will be broadcast on WBUR-FM, a noncommercial radio station with a 100-mile radius in the Boston area.

The format of the show will feature a guest who will speak on a topic of his choice and answer questions from listeners, according to Richard Gardner, host and originator of the show.

The program will also include news items of interest to the home computer hobbyist and a weekly announcement of resources related to the speaker's topic.

The program will be available to other stations and parts of each program can be broadcast as separate programs.

Further information can be obtained from Gardner at Box 134, Harvard Sq., Cambridge, Mass. 02138.

THE FEES DEBATE

I used to sit back comfortably secure in the thought that the people who run our country and agencies such as the FCC were so much brighter than myself, but now I really am worried. I just heard today that they (FCC) are going to eliminate all license fees from CBers and hams. I sure don't understand this. From one side of the FCC's mouth comes word that they don't have enough money to police the wild antics of the CBers, and from the other side they say we have so much money, let's forget the license fees.

The wild rush to the CB bands had already started one quarter of the way when the FCC decided to lower the rate to $4.00 from $9.00. It definitely wasn't lowering the rates that increased the CBers. Maybe the FCC didn't know how to handle the tremendous amount of money that would have come in if they left it alone. My calculator does not go that far, so I can't tell you how much money would have come in.

Does the FCC think that by dumping the $9.00 it will increase the ham ranks? When a prospective ham is ready to spend from $700 to thousands for ham equipment, what difference would $9.00 make? I would sure be interested in knowing how much money the FCC throws away by dropping the fee from $9.00 to $4.00. I wonder how many men could have been hired by the FCC in each state for police action by the money that was thrown away.

Harry Torossian WB8SWD
Dearborn Heights MI

FREEDOM OF INFORMATION

Thomas Houser, Director
Office of Telecommunications Policy
Washington, D.C.

Dear Mr. Houser:

Your recent letter to FCC Chairman Richard Wiley claims that "the federal agencies that compromise the OTP-chaired Interdepartment Radio Advisory Committee have studied all of the frequency bands currently under government control to determine whether any additional spectrum might be made available for Citizens

Briefs

Compiled by Warren Elly WA1GUD and Stan Miastkowski WA1UMV

How many times have you spent the day getting to the nearest FCC office, struggled through an exam, passed, and dragged yourself home . . . only to wait two or even three months for your new license? It's frustrating, and soon to be a thing of the past. Field Offices, starting sometime in March, will issue temporary authority for amateurs to use their new privileges before receiving the Gettysburg paperwork. The temporary permit will be good for 90 days and will require special identification while operating under temporary status. FCC's Greg Jones told *73* the March target date wasn't definite, but instead a goal.

The Long Island Mobile Amateur Radio Club (LIMARC) ATV repeater became operational on a regular basis at the end of January. The 439.25 in, 427.25 out machine is located in Plainview NY on a 320 foot antenna. It has an ERP of 200 Watts and is omnidirectional, allowing amateurs within a 20 mile radius to use its facilities.

Ed Pillar W2KPQ, Chairman of the LIMARC ATV Committee, and 30 members built the machine in their spare time from converted components. Most of the equipment and parts were donated by local industry and salvaged from various commercial sources. The club estimated the total cost in the vicinity of $2000, and will be running an experimental educational program on amateur radio and basic electronics in three schools within the Syosset NY school system.

The club is also planning to move its weekly technical net to the ATV repeater, with the visual medium giving an added punch to technical discussions.

The one year grant for the use of the 420 to 450 MHz band for experimental ATV repeater operation was issued on February 27, 1976. LIMARC has asked the ARRL board of directors to petition the FCC for a *five* year extension of the grant, citing the fact that last March the FCC granted offshore radio location (HIRAN) an extension for that period of time.

Ed Piller W2KPQ, Chairman LIMARC ATV Committee, with ATV repeater.

The FCC's proposal to deregulate (and decontrol) repeaters (see Guest Editorials and FCC) has drawn mixed reviews from the Ohio Area Repeater Council. Meeting January 8th, two days after the FCC proposal was released, the council voted 55 to 6 *against* elimination of repeater sub-bands, repeater licenses, and repeater callsigns . . . as Docket 21033 calls for. Instead, the council's officers were instructed to file comments with the Commission, "asking for continuation of repeater sub-bands, licenses, and callsigns, and for establishment of procedures by which the FCC will secure the comments of frequency coordinating groups such as the Ohio Council before acting on an application for a repeater license." The Ohio group did like the FCC's plan to simplify logging requirements and restrictions on remote bases and auxiliary links. Thanks W8GRG.

The Amateur and Citizens Division name change wasn't supposed to take effect until January 20th . . . but receptionists were answering the phone with the division's new name ("Personal Radio Division") the week before. There are no changes in the division's operation as of now, but the future could incorporate other radio services like private aircraft and marine.

Even if you try to pay the FCC for your new license or renewal, the Commission will still refuse. As reported last month, all fees were suspended by court order, effective January 1st. If you do send a check, the FCC will destroy it, and advise by mail. Cash or money orders will be refunded by government check. FCC officials, at press time, were still investigating retroactive refunds dating back to the court decision's effective date.

Topics expected to come up at the January 20th ARRL Directors meeting included a hike in League dues and a formal vote on the League's reply to the FCC docket on WARC. Some sources said they expected dues to go up $12 in the US, with the cover price of *QST* up to $2. (We'll have an update in Briefs next month.) On WARC, a letter to ARRL directors shortly after the FCC released its WARC proposal indicated the League would continue to push for new allocations at 10 MHz. See comments of Dave Sumner K1ZZ in last month's WARC report.

The case against Irael Treger W9IVJ continues in Chicago. Illinois Assistant Attorney General John McPhee says things are proceeding slowly, with the latest developments only promising further delay. McPhee is trying to get a court injunction barring Treger's company (Trigger Electronics) from advertising or carrying out business by mail. Over 350 people have complained that they mailed orders to Trigger, received their cancelled checks, but never got what they ordered. According to McPhee, about a third of the complaints have now been settled, "either to the total satisfaction, or partial satisfaction, of those concerned." However, with Treger hospitalized after suffering a stroke in early January, the chances of most victims recovering their money begin to fade. As McPhee put it, "The Judge may well tell us to leave Mr. Treger alone, concluding he has suffered enough already." In other words, after months of stonewalling the AG's demands for financial statements and depositions, Irael Treger continues to send out his catalogs and collect money from unsuspecting customers . . . and it seems like the courts may let him get away with it. Justice, anyone?

The role of amateur radio as a valuable public service was once again demonstrated after an earthquake in northern Italy last May. Details of amateur radio's part in the disaster have just become available. Repeater stations survived the shock and passed the word of the quake to the outside world. Next day 200 members of the Italian emergency corps established an emergency network to assist authorities in rescue efforts. The activity continued for nearly two weeks and was acknowledged with thanks by government authorities.

The on-again, off-again "Big Noise," the broadbanded buzzsaw interference that has been disrupting worldwide communications, was off at press time. A high-placed FCC source said that the Washington offices had received no complaints since the first of the year.

The noise had tapered off toward the end of 1976, and the FCC added that there seemed to have been a concerted effort to keep the noise out of the maritime and aeronautical safety services.

As reported in *73* last month, the Soviet Union admitted that the noise was coming from their country and was an "experimental use of the radio spectrum."

World mass media picked up the story toward the end of 1976 and speculated about the nature of the noise. Although many experts consider the noise a propagation study, some journalists have theorized that it was an experiment in the disruption of worldwide communications which could be used to create havoc with an army's communication during a war. Yet another farther out theory considers the possibility of the development of a "death-ray."

Whatever the nature of the noise, it seems to be gradually disappearing. FCC spokesmen did add that any further reports would be appreciated, including the time, frequency, and type of interference.

Just before press time, the "DX Jukebox" program of Radio Nederland in Hilversum reported that the Reuters News Service had quoted the Norwegian Defense Minister as saying US intelligence sources had indicated the radio interference was from a very powerful Soviet over-the-horizon radar, which could track aircraft anywhere in the world. Due to the extremely long range of the radar, it had to operate in the HF band rather than the UHF or VHF spectrum. It was further stated that the interference was coming from four transmitters, two located near the city of Kiev and two near the city of Nikolaev, both in the Ukraine.

The largest radio telescope in the world for ultra-short wavelength study has just been completed near the Amherst campus of the University of

Massachusetts in the western part of the state. Dr. Richard Huguenin, Director of Radioastronomy, in a *73* interview said the 45 foot dish has been under construction for nearly three years. It's fully steerable and enclosed in a geodesic dome.

Radiowaves in the one millimeter region (300 GHz) will be studied in an effort to understand interstellar molecules and their role in the birth of stars.

The installation was funded by the National Science Foundation and the Commonwealth of Massachusetts. It will be used by scientists from around the world.

Lowdown is a new monthly newsletter designed for the interest of LF band enthusiasts 540 kHz and down. A one year subscription is free to anyone who sends 12 SASEs to H. John Clements, 9010 Tobias #258, Panorama City CA 91402.

Persons involved on both sides of the RTTY/repeater controversy on 146.70 MHz in the Ohio area continued to take hard lines at press time. As reported in the January issue of *73*, Robert Scott W8FSK organized RTTY enthusiasts to protest a new 10/70 repeater on the frequency, which had been used for RTTY nets.

A great deal of correspondence between RTTY operators and the Ohio Area Repeater Council was generated, and the Council took up the issue at its January meeting. According to the minutes of the meeting, "It was agreed that if the individuals concerned had requested approval of 10/70 for a RTTY repeater before the voice repeater group asked for the pair, the RTTY request would have been approved. However, as there has been no such request, and in view of the use of other repeater pairs for teletype elsewhere in Ohio, the membership confirmed its earlier approval of 10/70 voice repeaters, and reaffirmed its decision not to reserve any repeater frequencies for direct use on either RTTY or voice."

Scott vowed to continue the fight against the use of 146.70 for voice. With the situation deadlocked, bad feelings abound and both sides seem to be drifting farther apart.

Opinions vary on the success of "Repeater Appreciation Week" in California the first week of January. Twelve major systems and virtually all of the minors shut down for a five day period from January 1st through 5th. The shutdown was caused by increasing abuse and bad language on many repeaters in the state. WR6ABE was shut down for two months last fall because of the severity of the situation on that machine.

During the "appreciation" period, control operators monitored the input frequencies for emergency traffic. No major problems were reported, although some of those alleged to have caused the trouble appeared briefly on some of the machines left on.

By shutting off machines, owners and control operators hoped to motivate users to self-police the offenders. Many systems came back under rigid control of operators and were immediately shut off again at the first sign of jamming or bad behavior.

Although first reports after the resumption of normal repeater activity showed a noticeable decrease in bad behavior, the next few months will tell the story about the future need for more appreciation periods.

St. Nick put out a lot of HO HO HQs on 2 meter FM.

Looking for Smokey? Owners of Drake series R-4 receivers can now tune in to CB channel 19 by doing the following: Set the band selector to 28.5 MHz and the "xtal" switch to 160 meters. Rotate the preselector to 15 meters and the dial to read 535. 10-4 and thanks again good buddy to the Santa Barbara CA Amateur Radio Club.

As reported in the February Briefs, the Bicentennial Relay project had become bogged down in red tape. Congratulatory messages from 45 governors and the Mayor of the District of Columbia to President Jimmy Carter were held up for nearly two months, while Bill Miller K4MM pressed for an appointment. In Chicago, where the idea got started with the local Quarter Century Wireless Association Chapter and Eric Shalkhauser W9CI (a participant in the first Presidential Relay held back in 1916), Lee Knirko W9MOL tried to interest the media with little success. A Chicago press conference drew only one reporter, and in Washington it was much the same story. The messages were delivered January 12th to Mr. Carter's appointments secretary, Fran Voorde. An appointment with the President prior to his inauguration proved impossible for two reasons: Mr. Carter's busy schedule and the Secret Service's reservations. The SS reportedly worried that if the hams got a chance to present the new President with the messages, "every group in the country would try to do the same thing." *That*, in the security conscious minds of the SS, would be a major no-no. (Incidentally, W9CI's fine history of ham radio begins with this issue of *73*.)

An unemployed engineer, complaining that waves emanating from a car's citizens band radio caused him pain, hurled a cinder block through the car's windshield yesterday, police said. Two Nassau County police detectives riding to work in the car immediately arrested the engineer.

Police charged James O. Nelson, 32, of 2 Norway Pine Drive, Medford, with third-degree criminal mischief, a felony, and second-degree reckless endangerment, a misdemeanor, and District Court Judge Warren Doolittle ordered him held in lieu of $1,500 bail. The detectives, George and John Staudt, were not hurt. The two are brothers.

Nelson, a former employee of the Grumman Corporation, allegedly stepped from the curb at Farmers and Stewart Avenues in Bethpage at about 8 am. Police said he threw a nine inch by 12 inch cinder block through the windshield of George Staudt's car and walked away. The detectives went after Nelson and arrested him. The car had been stopped at the intersection for a stop sign, according to police, who said the Staudts were on their way to work in the Eighth Precinct. *Reprinted from* Newsday, *Garden City, LI, NY.*

Members of the St. Jude Hospital Amateur Radio Club and the Southern California ATV Club staged an ATV "first" on December 22. They made it possible for patients at the Fullerton hospital to talk with Santa Claus while viewing him on 432 MHz color ATV.

The project was set up by Joe Moell WA6JFP and XYL April WA6OPS, Director of Occupational Therapy at St. Jude's. The TV signal source was the hospital's color TV camera, with 432 MHz equipment provided by Ernie Williams WB6BAP and John Verna WA6CAS of the SCATV Club.

Santa visited each room in the pediatrics and long term rehabilitation units of the hospital by means of a battery-operated color TV set and ATV converter, wheeled from room to room. Patients talked back to Santa on 2 meter FM simplex. A realistic "set" for St. Nick was made by hospital therapists, and background sound effects of reindeer and workshop elves came from an endless tape loop. In order that there be no doubt of Santa's authenticity, he was thoroughly briefed beforehand of each patient's name and background.

Newsfilm of Santa's ATV visit was shown to all of Southern California Christmas Eve on a Los Angeles television station. Thanks to WA6JFP for story and photos.

The antenna zoning case of Walter Weber WA9FXG has not yet been settled. In January, *73* reported that Weber has been ordered to remove his 72 foot tower and antennas. The fight against the Des Plaines IL city council has so far cost Weber nearly $2000 out of his own pocket. At press time, it appeared that the city council was dragging out the case through numerous legal loopholes in an effort to drain Weber financially.

In court late in December, the Des Plaines city attorney filed a motion to have Weber's suit against the city council dismissed. Because no reason was given, the motion was denied. The city then filed a point by point denial

Ed Webb W9IPO, President of the Chicago Area Chapter, Quarter Century Wireless Association, sponsors of the Amateur Radio Bicentennial Relay, Prof. Eric (Shaw) Shalkhauser W9CI, Honorary Chairman, receiving award in Chicago of message from President Gerald Ford, with Lee Knirko W9MOL, Relay Chairman. (Photo by John Bayalis W9CSA)

of Weber's suit.

Most antenna zoning cases have been quietly settled out of court in the past due to vague zoning laws. This case appears to be the first in Illinois and one of the first in the country to actually reach the courtroom. A negative decision could make it difficult for amateurs to erect antennas anywhere in the country.

A fund has been started in an attempt to help pay for the legal costs of the tower battle. Contributions can be sent to WA9FXG Tower Fund, c/o Hajek & Hajek, Law Centre, Mannheim & Roosevelt, Westchester IL 60153.

73 West Coast Associate Bill Pasternak reports that although the 1977 SAROC in Las Vegas seemed well attended, complaints abounded from both amateurs and exhibitors. Early arrivals found that the hotel reservations had been almost totally fouled up and some were forced to return home before the proceedings began. Many remarked that the speaker programs were "bad." Amateur manufacturers and distributors who exhibited were bothered by the lack of interest from the crowds. Most of the advance sales had gone to microprocessor enthusiasts, despite the fact that only two micro manufacturers were represented in the exhibit hall.

Many exhibitors who had been at SAROC in the past were absent this year. One said he would not be back, adding that SAROC is a "dud, and getting worse every year."

A number of new products were shown at the show. Among them was the long-awaited Dentron MLA-2500 linear, as well as a new Drake transceiver, the TR-4CW featuring a switchable CW filter. Amateurs got a first look at the previously announced Atlas 350-XL, with digital readout and 350 Watts out. More HF equipment made its debut with two new rigs from Ten-Tec, the Triton IV, yet another digital readout unit, and the Century 21, a 70 Watt allband rig.

With the large part that VHF is playing in amateur radio these days, the majority of new equipment was for that part of the spectrum. VHF Engineering introduced a new line of 2 meter amplifiers. The record for mobile 2 meter amps will now go to TPL, who introduced a *250* Watt unit. Kenwood was showing the TS-600, an all mode transceiver for 6 meters that should be available soon. KLM introduced the VFO-711 for their 2 meter rigs.

Accessories were well represented with new crank-up towers from Tristo and Wilson, as well as Wilson's super heavy duty rotator, capable of turning half a ton.

One unique product was the Astro 200 transceiver from CIR. It has digital tuning that is done automatically in 100 kHz steps. You push a button up or down for tuning in the corresponding directions.

Dale Hoppe K6UA of Fallbrook CA is the proud holder of the second WAZ certificate for 75 meter phone, and the first for the northern hemisphere. An avid DXer since being licensed in 1941, Hoppe started working toward the certificate in January of 1973 and received it late in 1976.

When asked about the toughest zones, Hoppe said that the last, zone 23, was the most difficult. A confirmed QSO there with UA9NH/JT-1 in Mongolia put him over the top. Adding to the difficulties, zones 15, 16, 17, and 18 required long path propagation.

The first WAZ for 75 meter phone belongs to Dr. Juan Fernando EA8CR in the Canary Islands.

Hoppe uses a Kenwood driving a Henry 2K. His antenna system is a directive curtain using four delta loops, two driven and two parasitic, giving a 10 dB gain.

He is active on all bands, including 2 meter FM and SSB, and holds a WAZ on 15, 20, and 40, as well as a WAC for 160 meters.

After nearly a year of operation, an amateur radio club formed to promote the use of SSB on 2 meters is expanding at a rapid rate. The "Side Winders On Two" headquartered in Fort Worth TX has over 300 members located all over the country. Nets have been formed on 145.10 MHz to demonstrate the potential of the 2 meter band and the SSB mode for rag chewing and DX.

Requirements for membership are working two members on 2 meter SSB. A list of members and further information on membership can be obtained from George Bretz, Treasurer, Side Winders On Two, 3520 Livingston, Fort Worth TX 76110.

It appears that the USSR is on the verge of launching an amateur radio satellite. Persistent rumors coming from Soviet amateurs put the launch date at sometime in the spring.

Nearly a year ago, several Soviet hams told AMSAT in Washington that the satellite was built and was undergoing final tests. It was not launched due to an unexplained delay.

Details were sketchy at press time. An issue of a Soviet amateur radio magazine showed a picture of a 2 to 10 meter transceiving installation and hinted at its use for a new satellite.

Both OSCAR 6 and OSCAR 7 continue to have battery problems. At press time, AMSAT president Perry Kline told *73* that telemetry data was still being gathered, but it appeared that one of the 18 cells in OSCAR 6 had failed. Instructions were given to command stations to change the voltage rating at which the satellite was shut down.

AMSAT was considering two theories in an attempt to rejuvenate the cell. One was to charge it vigorously for a period of time. The other was to continue to discharge the battery and then recharge it. Each of the 18 cells supplies 1.8 volts at full charge.

OSCAR 7 developed a problem with one of the solar panels, causing a voltage reduction aboard that spacecraft. Kline said that it was expected that OSCAR 7 Mode B orbits would be switched to Mode C until at least the end of February (Mode C is Mode B at half power).

Plans are continuing for a concerted fund-raising effort for AMSAT. As reported last month, funding for OSCAR 8 and the Phase III satellites is a problem. AMSAT officials are considering several avenues for seeking contributions and still seek new members and volunteers. AMSAT is located at Box 27 in Washington DC.

The famous sound of Morse code's dah-dit may be phasing out for the maritime industry. This is because two communications satellites are in synchronous orbit over the Atlantic and Pacific oceans. These maritime satellites, built by Hughes, are owned and operated by a consortium of carriers headed by COMSAT General Corporation. Called Marisat, the satellites are currently relaying high-quality voice, telex, facsimile, and data over both oceans for the international maritime industry. Marisat also serves the US Navy for fleet communications.

A third satellite, for Navy use and commercial backup, was placed in synchronous orbit over the Indian Ocean last October. Four-foot-diameter ship antennas allow ships to make instant contact with home port or to be reached instantly by ship telephone. Ships can also reach other ships via the system's ground station for telex messages.

Reprinted from IEEE Spectrum, *The Institute of Electrical and Electronics Engineers, Inc., New York NY.*

Collins Commercial Telecommunications Division of Rockwell International has received a $25.5 million contract from the Corporation for Public Broadcasting (CPB) to build an earth station system.

Collins will provide an earth station system comprised of 150 to 165 stations for the new nationwide satellite-based television system that will serve the Public Broadcasting Service (PBS). It will be the first large scale application of small earth terminals for television distribution by satellite in the United States.

Collins will provide a turnkey station which will include receive-only ground terminals, interconnect links, and services such as frequency coordination and site selection, prototype and qualification testing, site preparation, construction, installation, and long term maintenance support.

With the new satellite system, PBS will be able to broadcast multiple programs to public television stations simultaneously, enabling each station to decide which program to air and which one to tape for later showing. The new system will also enable PBS to provide additional channels to enlarge programming options for various groupings of its stations.

The new system is designed to provide flexibility and access to public television stations not previously financially possible, and expansion of the PBS interconnection using its new satellite system will be less complex and costly than at present. Under present conditions, linking up of a new public television station often takes two to three years. With the new system, PBS can have a new ground terminal installed as quickly as the equipment can be erected and frequency coordination requirements met. Also, the costs of interconnecting new stations in the satellite mode are substantially less than such costs in the present terrestrial mode.

Signal quality will be improved with the new satellite system, because a single signal will be picked up at approximately equal strength by each receive-only ground terminal. Distance has little significance, of course, and signal deterioration will not occur as it does in terrestrial systems.

The new public broadcasting satellite system will utilize three transponders of Western Union's WESTAR satellite to beam signals across the continental US, and to Alaska, Hawaii, Puerto Rico, and the US Virgin Islands.

The basic television receive-only earth station system will include 10 meter "nominal" antennas, low-noise amplifiers ranging in temperature from 50° Kelvin to 300° Kelvin, and the new Collins 55U3-1SC frequency agile video receiver.

The single shelf receiver can be tuned locally or remotely to any of 500 channels in the 3.7 GHz to 4.2 GHz band. It also features a maintenance logic unit that can diagnose faults to the replaceable module level and an ac/dc dual-voltage power input capability for redundancy of primary power, if desired.

The terminals will be designed for a video signal-to-noise of 53 dB assuming a video peak deviation of 13.5 MHz and a carrier-to-noise of 14 dB minimum.

The PBS satellite system is expected to be operational by the fall of 1978.

Collins has been involved in satellite communications since the early 1960's, when Collins engineers transmitted video, voice, and data signals from Iowa to Texas by bouncing them off the orbiting Echo balloon.

A growing trend on repeaters is the running of simulated emergency nets on an unscheduled basis. The nets give emergency coordinators an indication of the areas covered by the machines used and the availability of volunteers, as well as being a valuable training exercise. How about trying the idea on your repeater?

The Santa Barbara CA Amateur Radio Club reports that you can't beat CW when it comes to a tough communications path. Recently, a pleasure boat in the Santa Barbara Channel asked for assistance on the CB REACT network. Because of radio problems, the boat could not be understood. Dave McCollum WA6RGJ was on duty. He determined that the boat owner was familiar with CW, had

him switch the radio to SSB, and key the mike in CW. The message was then passed successfully.

It may be that 2 meter rigs will be as common as CB radios on the shelves of the nation's large retailers. The two largest mass merchandisers in the country, Sears Roebuck and Montgomery Ward, are both in the process of testing the water in the selling of ham gear.

The spring-summer edition of the 1977 Sears catalog has a 2 meter rig sitting beside the CB listings. The 22 channel rig is accompanied by a full explanation of ham radio and a caution that a license is needed for operation of the unit.

A spokesman at Yaesu Electronics in California admitted to *73* that the Sears unit is manufactured by Yaesu in Japan, but is not offered under the Yaesu name in the United States.

Meanwhile, the Montgomery Ward store in Plattsburgh NY is the site of a test marketing program for amateur radio gear. Michael Hanrihan, communications products manager for the store, told *73* that he was in the process of contacting major amateur product manufacturers in an effort to build a complete choice of product lines. At press time, Hanrihan admitted that he was getting little support from the companies that he had contacted. Of three major manufacturers contacted, one insisted that the entire line be purchased, one promised to call back but never did, and one gave Montgomery Ward an outright negative answer, saying that they did not want to jeopardize their existing dealer structure.

Another roadblock put in front of Montgomery Ward was a requirement that they take care of all warranty work. Although the amateur department may not be as full as first envisioned, the store was successful in obtaining the Midland line of 2 meter rigs.

Top officials at both Sears and Montgomery Ward were reluctant to comment on their future plans regarding the amateur market. A Montgomery Ward official said that the success or failure of amateur products at the Plattsburgh store would be studied over a one year period. If the pilot program is successful, the company may consider adding an amateur department to all of its retail stores, as well as the catalog.

The reluctance of major amateur products manufacturers to consider mass merchandisers draws an interesting parallel to a situation which existed in the photographic industry nearly ten years ago. At that time, manufacturers of advanced amateur cameras and accessories were reluctant to sell to mass merchandisers, fearing a complete loss of business in photo specialty stores. When one company broke down and decided to enter the market, others soon followed, and a number of discounters suddenly were equipped with fully stocked photo departments. Instead of taking business from specialty retailers, the increased availability of the products created a whole new market which all shared. A vastly larger distribution network for amateur products could possibly create enough demand to give amateur radio thousands of new devotees.

Trio-Kenwood digs in hard to officially break ground at the site of their new offices in Compton, California. The 23,000 square foot structure is being built to TKC's specifications by Nova Construction Company and is scheduled for completion in April, 1977.

The problem of CB radio theft has finally come to the attention of the federal government. Several congressmen, including Senator Thomas Eagleton of Missouri, have introduced legislation into Congress that would make CB radio theft a federal offense. Two bills were introduced last session, H.R. 13222 and 13223, that would make such theft punishable by a possible $5,000 fine and one year imprisonment. The bills specify that a transceiver missing for over 24 hours would be considered to have crossed state lines, thus allowing federal law to take effect. All mobile transceivers would be covered under the proposed laws, thus including amateur two meter gear which is also highly susceptible to rip-off. However, in a conversation with Senator Eagleton's office, *73* was informed that the two bills had "died" when the last session of Congress ended. It is hoped that they will be reintroduced when the change of administration is complete.

The London Ontario Amateur Radio Club reports that a number of Canadian amateurs are having problems passing through customs with amateur units when returning from trips into the United States. The depressed market for 23 channel rigs in the U.S. has made them attractive to a number of Canadians. Since border personnel may not be aware of the difference between amateur and CB rigs, Canadian amateurs are urged to carry a photocopy of their license and the bill of sale for the radio. When entering the U.S., they should have Canadian customs officials fill out form Y38, which will record the unit as having left Canada and should facilitate easy reentry.

Tired of waiting for QSL cards from slow DX stations? Have patience. Two years ago, scientists at Jet Propulsion Laboratories in Pasadena CA sent a message to a star system that they believe has a high probability of having habitable planets. If an answer is sent back as soon as the message is received, it should be arriving here on earth in 48,000 years. Is a new WAG (worked all galaxies) certificate far behind?

The US State Department has announced success in its negotiations with The Republic of the Philippines. A reciprocal operating treaty was the result, effective October 25th.
From ARRL Bulletin.

We've been getting some letters from MARS members of late, complaining about changes in their calls. Marc Leavey WA3AJR wrote of his belief that the FCC had purposely shuffled MARS calls to grant special bicentennial calls to the general amateur population.

"A little more than two years ago, the three MARS programs operated just as they had for decades. Upon entering MARS, an amateur would assume a callsign based on his FCC issued identification. The scheme was, where "n" represents the FCC Call District, thus:

Prefix	Army	Navy	Air-Force
Wn	An	N0	AFAn
Kn	AAn	N0	AFBn
WAn	ADn	N0	AFCn
. . . etc.			

"This was all well and good until about two years ago, when we were informed of a change.

"It turned out that the FCC had determined that the calls we were using on the MARS frequencies were illegal. The prefix 'AD3', as in AD3AJR, for example, was not a USA call at all, but rather one assigned to the tiny nation of Lower Ugorgi, or some such. Thus, to comply with international treaty regarding amateur callsigns, a change was in order.

"This declaration was of note for several reasons. First, it has been established in many other cases that the MARS program does *not* fall under the jurisdiction of the FCC, but of the Inter-Agency Board (IAB), a faceless group which looks over military and government radio use. Further, there is no reason for MARS callsigns to follow amateur regulations as operation is not under the Amateur Radio Service rules, nor is it on amateur frequencies. Certainly the 'Command' stations, WAR, AIR, NAV, and NPG, have calls which do not follow amateur convention.

"Nonetheless, without a whimper, we complied. Our reward was:

Prefix	Army	Navy
Wn	AAMn	NNN0
Kn	ABMn	NNN0
WAn	ACMn	NNN0

"Air Force was unchanged, Army got jawbreaker calls, and Navy people started stuttering!

"Then came the Bicentennial and the famed bicentennial callsigns. Looking suspiciously like the 'illegal' Army MARS calls, which were never heard on amateur frequencies, use of these 'special' prefixes was encouraged on all ham bands, especially in international contacts. Remember:

W = AC
K = AD
WA = AA
WB = AB

"Do you think, maybe, the *real* reason for changing the MARS calls was to provide the block for Bicentennial use?

"Well, now it's 1977, a new year. The celebration is over, the calls are gone. Of course, the FCC is now issuing the old Navy calls to amateurs (NnXX), having finished with the Army/Bicentennial calls. Is there any hope for us to get our old calls back?"

Marc I. Leavey, M.D.
WA3AJR-ACM3AJR
(ex-AD3AJR)
Randallstown MD

We're checking. Meanwhile, what about the scuffle for 1 x 2 callsigns? It's gotten to the point where you don't know whether you're talking to a seasoned veteran or an 18 year old kid. (More on the FCC's callsign shuffle next month.)

There *is* a place where Technican class licensees can operate SSB on HF, and where Novices can operate voice on 2 meter FM. It's the Military Affiliate Radio System (MARS) which is always looking for dedicated traffic handlers. Besides the extra privileges, MARS licensees are issued distinctive callsigns and are given access to surplus equipment. MARS units in many areas of the country are currently running membership drives. For further information, write: Commander U.S.A.A.C., Attn CC OPS OM, Fort Huachuca AZ 85613.

EDITORIAL BY WAYNE GREEN

from page 7.

from the FCC. We are still far too restricted by the FCC to be able to set up much in the way of gentlemen's agreements on the use of our bands. If the FCC were to throw out the bandwidth proposals now under consideration (Docket 20777) and remove all restrictions on modes of communications, we would then have a situation where we could start governing ourselves.

Since the repeater councils presently represent about half of the active amateurs, we have a good start. Most repeater clubs have expanded to be regular ham clubs, with many non-FM members. Those which haven't opened up to non-FMers should get their act together . . . how can you run Novice classes when Novices can't use FM? And what red-blooded ham club doesn't have a Novice class going these days?

Think about a structure for amateur radio founded on the radio clubs. Representatives of the clubs would meet with area councils to pass along the wishes of the clubs . . . and bring back the ideas from other clubs. Council representatives would meet to agree on changes in our agreements on subbands, modes, etc. This would permit amateurs to keep up with technical developments, and should encourage the pioneering of new ideas. This would take only a national meeting of councils to be put into effect . . . everything else is already in motion and working reasonably well.

Such a system would need a mode of communications . . . a forum where ideas for changes in agreements could be discussed . . . the pros and cons developed. It goes without saying that *73 Magazine* is available for this . . . it always has been. Clubs can't be sure of getting all the information they need to make intelligent decisions unless there is a relatively free press . . . and this comes down to *73*. *QST* is not known for allowing more than the ARRL side of things. *HR* seems to panic at any suggestion of offending *QST*, upon whom they are overdependent. I'll print just about anything in *73*, and whether I agree with it or not is irrelevant.

So there's an idea. You can let me know what you think.

MA BELL WISES UP

When Bell decided to use on-line signaling for long distance calls, a number of engineers advised against it. They pointed out that this would encourage the development of ways to defeat the billing for the calls. The engineers tried hard to convince higher-ups that they should use separate wires for signaling and thus avoid any problems with customers using signals of their own. The deaf ear turned to these engineers was not one of the brighter decisions made by phone company officials.

It was this decision to use the same wires for operating the dialing equipment as for the phone conversations which brought about the development of the red box, the black box, and eventually the blue box . . . devices for getting around some of the on-line signaling. The engineers raised a chorus of "I told you so" as blue box use escalated. I suspect that the phone company reacted by firing the wise guys.

At any rate, Bell has recently announced that they are at long last setting up separate lines for handling dialing. With some of the newer high speed systems, one set of signaling lines will be able to handle hundreds of customer lines, since few signals will take more than a second or two to transmit. Bell is trying out the new system in Wisconsin and expects it to be all over the country in a few years. This will greatly speed up connections on long distance calls and will make it possible to make collect calls without the help of an operator. It will also thwart any blue box fans who are still not in jail.

MAIL ORDER RIGHTS

Since a good number of the ads in *73* are mail order ads, it may be helpful to both prospective customers and mail order firms if I go over the new mail order laws.

The Federal Trade Commission has some rules which go a long way toward protecting the mail order buyer. It really doesn't pay to fool around with these chaps, so read on and see what they've done.

A customer has the right to know when to expect merchandise to be shipped. If no date is set by the seller, you have the right to have your merchandise shipped within 30 days. If the seller does not ship within 30 days, you have the right to cancel your order and get all of your money back. The seller must notify you of the delay and give you a free means (postage paid reply). If the delay is 30 days or less, you have the right to cancel your order and get your money back, the right to agree to a new shipping date, or the right not to answer . . . in which case the seller assumes that you agree to the shipping delay. If the shipping delay is more than 30 days, you must give your express consent to the delay, otherwise the seller must return your money at the end of the first 30 days of the delay.

If you cancel, you have the right to get all of your money back, and it must be mailed to you within seven working days after you cancel. On credit sales, the seller has one billing cycle to adjust your account.

If you have a problem, write to the dealer directly. If you don't get results, outline the facts, with a copy of the ad and a short letter, and send it to: Director, Bureau of Consumer Protection, Federal Trade Commission, Washington DC 20580 . . . and please send a copy to Wayne Green, *73 Magazine*, Peterborough NH 03458, so I'll know when a firm is lousing up.

A CALL FOR PAPERS

It wasn't very long ago, historically, that one of our ham magazines was calling for those unused frequencies between 146-148 MHz to be made into a new citizens band. It probably wasn't so much cooler heads prevailing as the glacier-like movement of the FCC which saved our present repeater band.

Today we hear that familiar cry of "use it or lose it" ringing out plaintively, echoing up and down our many virtually unused ham bands. One or two furtive teenagers calling CQ every night do not constitute much of a foothold on an empty ham band. And since there is probably no way in this world to get that old-timer's tuning knob unfrozen from 3999 kHz, where he's been for over twenty years, we have a desperate need for newcomers.

Many clubs are doing a great job of attracting new blood to hamming. The big source of beginners in amateur radio has been CB, now that amateurs have discovered there are some nice people on CB, much to their surprise. Where in 1973 only about 50 ham clubs had license study classes, now almost 3000 clubs are offering these, and the result is a ham increase during 1976 of 22,497 (according to the Callbook) . . . that's about an 8% increase . . . showing that while we haven't grabbed the brass ring, we definitely are back on the merry-go-round . . . to coin a phrase.

Prior to ARRL's "incentive licensing" fiasco, the ham growth had been about 11% per year for quite a few years. We certainly should get back on that schedule, at the least. I think we can do it . . . heck, I *know* we can do it. We had to live with zero growth for over ten hard years, so we're pretty rugged.

I see the key to growth lying in the expanding interest in CB. With millions of people becoming familiar with two-way radio, I think we can spark a hamming interest in this tinder.

To spark this interest, we need to tell the world about the fun of hamming. Oddly enough, hardly anything has been written by amateurs telling about the various hobbies that go to make up what we call amateur radio. I'd like to see papers submitted to *73 Magazine* on every facet of hamming. These could be published in *73* . . . put into booklets to go to CB clubs . . . booklets in radio stores . . . etc.

A paper should explain about one particular phase of amateur radio in terms a beginner can understand . . . it should be well illustrated with photographs and any drawings or maps which will help explain. The deadline for papers for this competition is May 15, 1977. Winning papers will be published and the authors will receive a certificate of merit for their contribution to the growth of amateur radio . . . plus a check for $250.

Papers which get honorable mention may also be published and will be paid for at regular rates . . . the fact is that any well done paper will probably be used in this drive to convince CBers (and everyone else) that they should get their ham tickets.

Major facets of hamming:

- DXing
- Contests
- Certificate Hunting
- SSTV
- RTTY
- ATV
- FM/Repeaters
- Public Service
- MARS
- Nets
- Traffic Handling
- Oscar/Amsat
- Club Work
- Home Building
- Antenna Experimentation
- Novice Classes
- Microcomputers
- QRP
- Mobile
- Moonbounce
- 160m DXing
- DXpeditions
- High Speed CW
- VHF SSB

Here is a way to have a lot of fun . . . to give a big boost to your own special interest . . . to help amateur radio in general . . . and to get some recognition. There's nothing like being published in the magazine to make you an "expert."

Since the main purpose of these papers is to attract newcomers to amateur radio, be sure to start out with something dramatic if you can. Emphasize the fun . . . be honest about the cost, but try not to scare off the beginner. Try to have the best pictures you can . . . black and white. You might plan for one color picture later if the paper is a winner . . . something that might be used on the magazine cover. This takes a very good camera and experience.

You might think of this as a way to help pay back amateur radio for the enjoyment it has given you.

WRITING FOR 73

What does an author expect from a publisher . . . in addition to being paid well and promptly? Well, there is a bit of vanity in all of us and we want to know that our ideas will get the best possible distribution. We want to reach those who will be receptive to our ideas.

Since *73* has done most of the pioneering in the ham field, most of the top name authors have tended to write for *73* . . . it is the best way for them to reach the people who count. There is no discounting the impact of *73* . . . for instance, it was *73* which brought FM and repeaters to general use . . . and it was the *73* push to get clubs to start hamming classes and get

New Products

HY-GAIN 3750 SSB/CW TRANSCEIVER

Every so often a truly unique radio appears on the scene, and after a few years it disappears almost as quickly as it arrived. The cutting edge is usually price. Signal Ones and HRO-500 receivers could only be afforded by a minority of amateurs, despite claims that hams are a wealthy, exclusive lot who can afford $2000 pieces of equipment. Figures I've seen recently project that hams will spend an average of $400 in the next 12 months on additional gear, and that doesn't seem to allow for many 2 kilobuck transceivers. The market then for radios like the Hy-Gain 3750 may be small, but it undoubtedly exists.

Hy-Gain has had its problems (*73* Briefs, February, 1977), but reorganization has divided the company's CB and ham divisions, and autonomy is bound to bolster the amateur side. A new 2m HT is now available (watch for a *73* New Product Review), and Hy-Gain's long-established line of antennas continues to sell well. The 3750 transceiver is the centerpiece in Hy-Gain's amateur plans for the future, and it represents state-of-the-art design.

Marketed by Hy-Gain here in the US, the 3750 is manufactured in Japan by National (no connection to the American company). Not many 3750s had reached the US at deadline, but by the time this issue gets to you, availability will be up. Most people we worked with the 3750 had never heard one before, and the radio caused quite a commotion as soon as stations realized what they were listening to. Several pileups were caused by the curious, but we couldn't find anybody who criticized the signal or the audio characteristics. The Hy-Gain has a distinctive sound, and many fellows were stumped trying to figure out what it was. Inevitably their reaction was, "Wow, that's that $2000 transceiver?" Yes, it is.

Okay, you're saying to yourself, "Why so expensive? What makes the Hy-Gain worth $2000?" Well, how about a phase locked loop circuit that locks the first local oscillator and VFO, resulting in direct injection into the 9 MHz first i-f, a total lack of spurs and images, dual-gate MOSFETs throughout the rf amplifier and mixer stages, a 20 dB pad . . . all in front of a narrow band SSB crystal filter? The CW filter is very sharp, but signals remain strong. A 50 kHz T-notch filter and 9 MHz crystal filter are designed to put the 3750 in a class of its own in notching unwanted signals. Then there's a gated noise blanker that functions like a squelch circuit in cutting pulse noise without reducing the receiver's ability to handle cross modulation. You really have to hear the 3750's receiver to believe it! After a few hours of using the Hy-Gain, it began to really show its stuff, sort of like learning to play an instrument. It's the best I've ever heard.

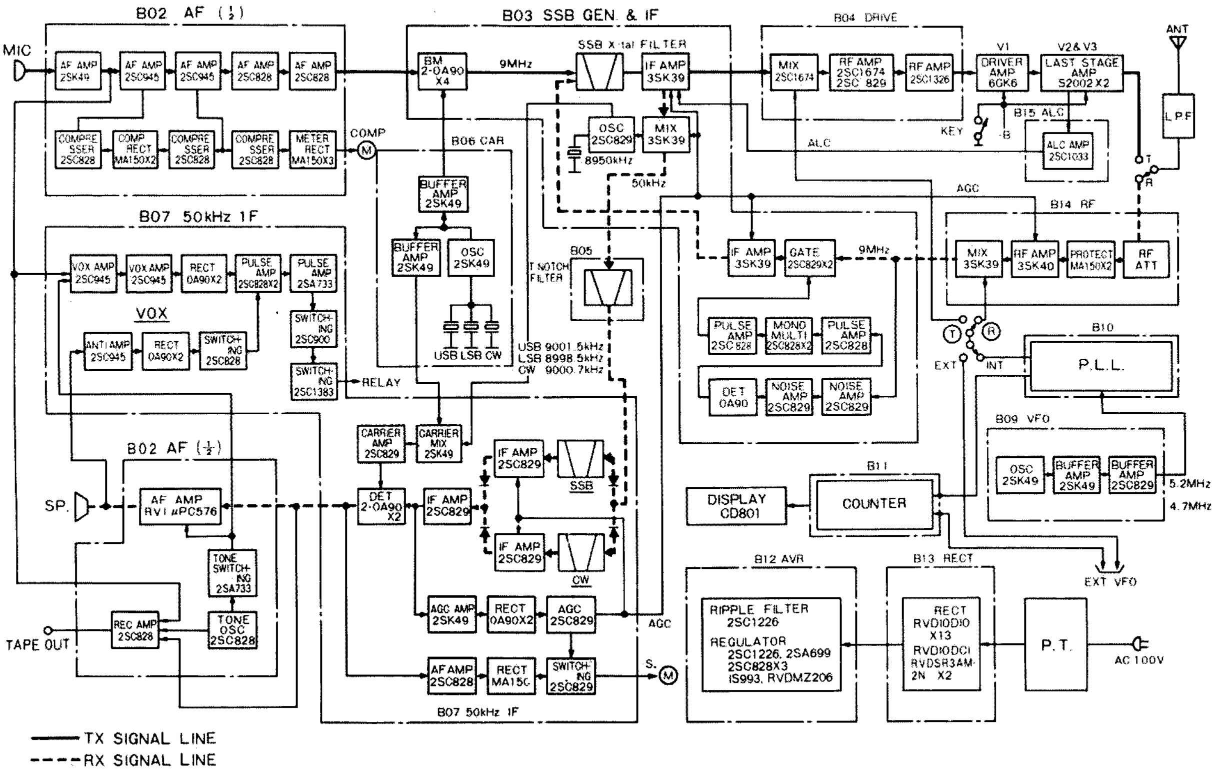
Our proving ground was 40m SSB, where broadcast interference and weak signals combine to produce enough noise to drive away all but the most dedicated DXers. It is uncanny how the 3750 sweeps the noise aside, through the use of notch filter, 20 dB pad, and noise blanker. As one *73* editor put it, "Using that rig on 40m was like talking on the telephone." He's right. Especially good is Hy-Gain's audio quality on receive, even on the built-in speaker. The speaker is mounted on the bottom chassis, but it never protested the wide variations in audio produced by tweaking the notch and noise blanker.

Dialing up a frequency is a simple matter of selecting a band, mode, and tuning the VFO until the digital readout displays the desired spot. If you go out of band, a series of LEDs flash on across the readout. The VFO's tracking is quick, so quick that you have to tune slowly . . . otherwise the counter will zip right by. RIT is included, of course, and when used in conjunction with the notch and blanker, it makes for easy copy in round tables and nets. The RIT actually registers on the LED readout, a feature unique to the 3750. Hy-Gain uses a bit different slant on memory readout than other transceivers employing digital readout. In the 3750, the memory LEDs are separate and allow off-channel tuning without the loss of the main tuning LEDs . . . other systems have only one set of LEDs that are switched between direct readout and memory readout.

The Hy-Gain 3750 is no mini transceiver. It weighs in at 44 pounds, and measures 16" wide by 7" high by 13" deep. Construction is solid, with a well laid out front panel. Band switching, final tuning, and RIT controls are to the right of the VFO. Receive controls are on the left with dual concentric pots for af-rf gain and mike level-audio compression. A row of toggle switches takes care of power (receiver only), heater (final and driver tubes), remote VFO selection, AGC range, compressor, and rf attenuation. A row of push-buttons covers modes and the tune position. Front panel jacks are provided for mike, headphones, key, and recorder output, with two rows of miniature pots for easy VOX adjustment, CW sidetone level, frequency counter calibration, and output meter sensitivity. The front panel is rounded out by a large well-calibrated multimeter which covers everything from plate current to compression level.

Band coverage goes a bit beyond complete. The Hy-Gain is set up for 160 through 10 meters, but more than enough extra coverage is included for MARS activity without the need for a remote VFO. A remote unit is available (model 3855) which allows selection of 7 crystal controlled channels. Interfacing between the transceiver and remote VFO is good, with the operator able to switch transceive functions between both VFOs, or separate receive and transmit.

Hy-Gain uses S-2002s (a pair) for finals, and a 6GK6 in the driver. Otherwise it's solid state all the way, with (counting the receiver as well) 98 transistors, 43 ICs, and 120 diodes. Construction is modular, with 21 boards (or modules) interconnected through computer type connectors,



Block diagram of Hy-Gain's 3750.

The Hy-Gain 3750 transceiver.

making for easy access to the boards. Hy-Gain provides an in-depth instruction manual of over 50 pages, covering everything from operating the radio to circuit theory. The manual is illustrated with many close-up photographs of the modules and scores of block diagrams and schematics.

The transmitter's main selling point is the audio system. ALC and audio compression are combined to keep average output up, and it works . . . using a monitorscope we were unable to make the 3750 flat top or distort. On-air reports showed a preference for the *compressor*, a point that underscores the effectiveness of the Hy-Gain's audio system. Use of a panadapter by stations 50 and 1500 miles away showed no evidence of splatter, even with mike gain and compression levels turned all the way up. Output was measured at 190 Watts on all bands except 10m, where the Bird meter indicated about 110 Watts out.

The basic Hy-Gain 3750 (completely self-contained with power supply and speaker) retails at $1895. By the time you add a remote VFO and remote speaker, you're well over $2000 ($2460 to be exact). The Hy-Gain, make no mistake, is an impressive radio. A solid month of operation by three *73* editors produced no problems, and lots of great QSOs. The 3750 is built like a battleship, and refused to bother even the most ancient and TVI-prone TV we could find. After removing the top and bottom covers (a job that takes patience and time due to the tremendous number of screws), still more shielding had to be removed. The design reminded us of broadcast equipment. And we were left with the strong belief that the 3750, like most high quality broadcast gear, would last forever. *Hy-Gain Electronics Corporation, 8601 Northeast Highway Six, Lincoln NE 68505.* Test unit supplied by *C & S Marketing Associates, Algood TN 38501.*

OPERATING IMPRESSIONS OF THE HY-GAIN 3750

I was especially impressed with the receiver. In a crowded 40 meter band one Saturday night, I was able to take a signal, which was down in the mud, and enhance it until it was of the quality only produced by locals.

Signal reports from throughout the country while using only a dipole antenna confirmed the fantastic output from the rig. Many comments were made concerning the fine audio, and I was told by many that I had one of the strongest signals on the band.

The built-in speech compressor seems to be of excellent design. After many on-the-air tests with distant stations, it appears that the compressor does its job to get the signal through without any noticeable decline in audio quality.

Tuning the rig is one of the easiest procedures I have seen; it is virtually foolproof.

For every hobby there is an "ultimate" unit. For the sports car enthusiast it's the Ferrari. For the amateur photographer, it's the Hasselblad. For the amateur radio operator, it's the Hy-Gain 3750 transceiver.

The 3750, besides being the most expensive amateur transceiver on the market, is also the best. It's state of the art, utilizing phase locked loop circuitry with dual gate MOSFETs in the rf amplifier and mixer stages.

The real beauty of the rig is the digital readout. In the 3750, you have not one but two. By flipping the little switch called "Memory," there displayed in front of you is the last frequency that you were on. No need to write it down. If you want to return to it, there it is. The second set of readouts also function with the external VFO, telling you where it's set. Talk about the arrival of digital electronics and convenience to ham radio – this is it.

73 TESTS THE TUNERS

At the risk of provoking more controversy over swr and antenna tuners, 73 proposes to test every antenna tuner we can get our hands on. We're not going to do them all at once, because more often than not those kind of articles end up a meaningless buyer's guide to manufacturers' specifications. Instead, we're running them one or two a month after operating the units over a period of time long enough to judge actual performance. Frankly, we're beating the heck out of them, trying to decide, among other things, whether those specifications we mentioned earlier are in fact realistic.

And about all that controversy on antenna tuners – matching networks will not turn your 200 Watt transceiver and 35' high dipole combination into one of the "big guns."[1] *That takes a good antenna. But if you lack the 10 acres you'd like for an antenna farm, and can't handle a behemoth antenna for each band, read on . . . one or two good antennas and a tuner could solve your problem.*

Take trap beams, verticals, and dipoles. Most are closest to "match" over a narrow portion of each band (often you have to choose phone or CW). Or fan dipoles, where the same elements are used on two or more bands, like 40 and 15 meters. In both cases there is a need for a tuner. Limited space is another reason. I'm living in an apartment, in a low signal TV area, with a 100' by 50' lot. The location's only claim to fame is three good size trees at the front and rear, with only enough room for two or, at most, three antennas (a tower could develop this spring, but only one tower, so I'll probably be forced to go the multi-band route there, too). Because of all this, an antenna tuner has become essential.

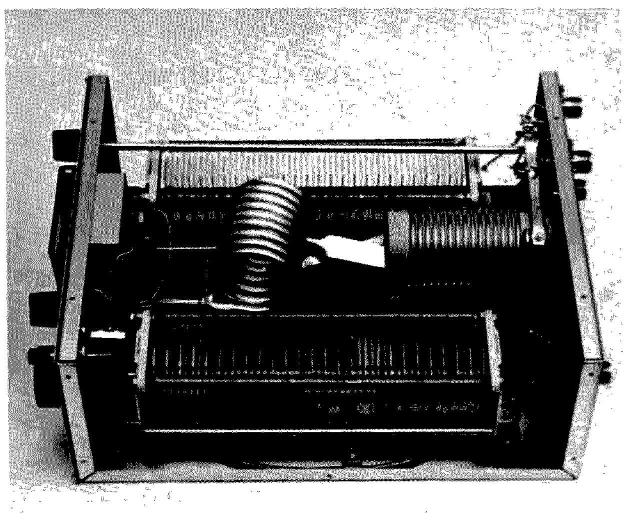
One more argument – the real impact of tuners is greater efficiency. Nearly everyone, on both sides of the swr controversy, can agree that transmitters run more efficiently when properly matched to a load. So far so good? It follows then that an antenna tuner can increase power output and prolong the life of your finals.

The debate continues over tube versus solid state transmitters, and even amplifiers are being caught up in it, as broadband output circuits catch on. Output really suffers when faced with mismatches that tube equipment finds relatively tolerable, so it may not be long before antenna tuners are as standard in ham shacks as swr bridges.[2]

1 Rayer, F. G., "Exploding the SWR Myth," *73*, Dec., 1976, p. 122; Woods, Hubert, "Exploding the Power Myth," *73*, Dec., 1976, p. 120.

2 *73 Magazine* Staff, "The Super Transmatch," *73*, July, 1976, p. 150.

The Drake MN-2000 2 kW matching network. Note antenna switching left, power meter swr controls right.



The MN-2000 with two layers of shielding removed. Silver-plated coils and swr-power meter PC board are clearly visible.

THE DRAKE MN-2000

Now that we've convinced you you need an antenna tuner, consider the Drake MN-2000. This is a high power matching network, capable of handling well in excess of the legal limit. The silver-plated switch contacts and tank coil are the first clue, along with the spacing of the MN-2000's nearly foot long tuning capacitors.

Drake's tuners (both the 2000 and 200 Watt models) are double shielded, with the typical Drake copper-colored chassis and black cabinet. SO-239 coax connectors are used throughout, with a ground post the only other rear panel connection.

The MN-2000 has been around for years, and the original design has held up well. Coverage is 80 through 10 meters with an insertion loss of less than half a dB. The Drake took everything an SB-200, Henry 2K, and Alpha 374 could offer . . . willingly. Even faced with extremely bad mismatches, the MN-2000 tuned easily and without the confusing series of dips usually associated with transmatches.

The Drake is really several station accessories in one — aside from being an antenna tuner, the MN-2000 serves as a wattmeter (comparing most favorably accuracy-wise with a Bird unit), swr bridge, and antenna switch. A large well-calibrated multimeter dominates the front panel, with wattmeter and swr controls right, and antenna switching for three antennas left.

A unique feature on the Drake is its ability to completely take the tuner out of the line, while maintaining wattmeter and swr functions. Two antennas can be switched in this way, with the third antenna switching position wired straight through (excellent for a dummy load).

The MN-2000 is a component of the Drake system and, like the rest of the Drake line, its layout is classic. (Those of you who didn't go through junior high dreaming about girls and Drake lines really don't know what you missed!)

The matching network is larger than the companion R4C and T4XC transmitter and receiver series, but not big enough to present a problem in most shacks. The controls are well laid out with a solid feel (the bandswitch leaves no doubt when it's engaged), and the tuning controls are large and operate smoothly.

Although designed for coax cable, the MN-2000 can handle open wire feeders with the use of a balun, and it worked fine with random wire antennas as well. The network is fairly broadbanded once tuned, allowing you to go as much as 100 kHz without touch-up. Tune-up can be a really quick procedure — if you take the time to tune each band and antenna, and draw up a chart plotting proper adjustment of the resistive and reactive tuning controls. The MN-2000's swr bridge uses a minimum of switching, with a spring-loaded sensitivity control doubling as a switch for forward calibration. The wattmeter is broken down into two ranges (200 and 2000 Watts) on the 3" by 2½" meter scale.

Some other features of the MN-2000 include its ability to put 2nd harmonics down 25 to 35 dB (thus helping to reduce TVI problems). I checked Drake's claim on harmonic attenuation by tuning for the 2nd harmonic on my station receiver (a Drake R4B), and sure enough, the S-meter indicated Drake's specs were accurate. Another nice feature is the fact that using the MN-2000, there is no need to retune the exciter when driving a linear amplifier, since the tuner shows a pure 50 Ohm load.

The best thing about the MN-2000 is probably its price. At a suggested retail of $220, Drake is well within competitive limits with other full legal power antenna tuners, in an attractive easy to operate package. *R. L. Drake Company, 540 Richard St., Miamisburg OH 45342.*

DENTRON 80-10 ANTENNA TUNER

Back in what are affectionately known as the "good old days," being an amateur was much simpler than it is today. That's especially true when it comes to putting up antennas. Large lots, pastures, and the wide open spaces were the rule. If you wanted a 70 foot tower — no problem. A 160 meter dipole? Just string it up.

For most of us, the situation has changed drastically. Apartments, condominiums, and small suburban lots have made things quite a bit more difficult. Our mobile population and increasing numbers of people have created space problems. Besides, why go to all the trouble of putting up a permanent installation if you're going to be moving in a few months or a year?

Fear not! There is an answer to the antenna problem. It's called the random wire. Having been around at the time of Marconi, it certainly can't be called a new concept. But with the space and time limitations of our society, it's a very logical solution to getting on the air.

So you've strung a wire out the window to the neighbor's apple tree. Now what? You need a tuner. A random wire tuner. The new Dentron 80-10 Skymatcher will fill the bill perfectly. This compact unit handles 500 Watts PEP, more than enough for any barefoot transceiver on the market. (If you're planning on running a full gallon, best bet is an orthodox antenna . . . any type.)

Although the home QTH in the hills of western Massachusetts has more than ample room for a large antenna farm, I tried out the random wire concept by spooling off somewhere around fifty feet of antenna wire and attaching it to a nearby barn. The Skymatcher has no swr meter, but my Ten-Tec Triton IV does, so I was able to get a quick indication of the match. What started out as a horrendous mismatch was soon brought down to 1.1:1 by the use of the antenna matching and inductance controls on the unit. The same was true on other bands. No problem at all.

For $59.50, the Dentron 80-10 is a solidly built little unit. After exposing the guts, heavy duty construction was evident throughout. The inductance control is a ceramic 12 position rotary switch. An SO-239 is provided for the feed from the transmitter, and the wire itself is attached to a ceramic feedthrough. A huge bolt is provided for attachment of the ground wire, a *very* important part of any random wire system.

Besides apartment or home use, the 80-10 is great for operating portable. String a wire between a couple of trees and you're ready to go. The continuous tuning from 3.2 to 30 MHz makes it easy. And don't forget that it can also match a standard antenna system. *Dentron Radio Company, Incorporated, 2100 Enterprise Parkway, Twinsburg OH 44087.*

THE KENWOOD TR-7400A 2m TRANSCEIVER

The recent growth of amateur radio has not gone unnoticed in the sales departments of major manufacturers. Conventions are being broken as companies devoted to VHF equipment move into the HF market, and vice versa. The relative price of equipment is being forced down where the competition is especially tough, and the prime battleground is 2m FM.

Surveys have shown that more than half the licensed amateurs here in the US are on 2m FM. Repeater frequencies are as valuable as gold in the big cities, and the situation is getting worse even in rural areas. More than 3000 repeaters are listed in the new 1977 *73 Repeater Atlas* (available now from Radio Bookstore, Peterborough NH 03458), and with recent FCC proposals to deregulate repeaters under consideration, the situation is bound to burst wide open.

Whatever the results, it's logical to predict that the new generation in repeater operation will grow out of 2 meters, with increased emphasis on crossbanding. Amateurs will probably be left with the decisions on what goes where, and it seems likely

Pitcairn Island

-- an inside look at VR6TC

All photos courtesy VR6TC and W6HS

Tom Christian VR6TC, Pitcairn Island, is one of the most sought after contacts in amateur radio. Tom is also a very celebrated person in his own right: He is a direct descendant of Fletcher Christian of *HMS Bounty* fame.

Mutiny aboard His Majesty's transport ship *Bounty* occurred just before dawn on the morning of April 28, 1789. Some eight and one half months later, on the 15th day of January, 1790, Fletcher Christian, who was the leader of that mutiny, eight of his fellow mutineers, six Tahitian men, twelve Tahitian women, and one infant child went ashore on Pitcairn, one of the world's most remote islands.

It was there on tiny Pitcairn Island that those twenty-eight people began a new life and a new breed of society to be known around the world as the Pitcairners, descendants of mutiny.

Thomas Coleman Christian, born on Pitcairn November 1, 1935, is the great-great-great grandson of the most famous mutineer in the world. And from what was a British naval disaster came the greatest sea adventure story in Western history. Many books have been written about this historical event and two movies, "Mutiny on the *Bounty*," were made. The latest movie had Fletcher Christian being portrayed by that famous actor, Marlon Brando.

When VR6TC comes on the air, it is no surprise that Tom will be a man in demand: The ham at this end not only gets to log a new country, but will have a momentary trip via amateur radio to a very historical place.

Tom's voice, Polynesian and British in accent, will be recognized almost the first time it is heard. It has a certain distinctive flavor all its own.

If you want something bad enough, and determination is a prevailing factor, you will succeed in your endeavor. In my case, it was a contact with Tom Christian VR6TC, Pitcairn Island.

The QRM, if you have never been in one of Tom's pileups, is absolutely unbelievable. I know, because from the first time I heard Tom until VR6TC was logged, almost a full year had elapsed. Since that day of success, I have talked to Tom on many different occasions. We have had a few schedules and during our many conversations I've learned a great deal about Pitcairn and VR6TC. I spent many more hours just reading the mail while Tom was talking to other friends he has schedules with. He is a very interesting person, even if you're only listening.

Pitcairn is a small rugged island of formidable cliffs of reddish-brown and black volcanic rock. It looms up from the sea in the middle of nowhere to a maximum height of 1100 feet. The island is only two miles long, and about one mile wide. It's about midway between the Canal Zone and New Zealand and some 3300 miles east-northeast of her nearest shipping point, Auckland, New Zealand.

To the south of Pitcairn there is nothing but open sea until you reach the icecaps of Antarctica. Her South Pacific location is latitude 25 04 south and longitude 130 06 west.

As you approach Pitcairn from the northern side, there will be a small indentation in the sheer inhospitable cliffs that surround the island. This will be the famous Bounty Bay, the only landing point for the island.

Bounty Bay is so named for it is only one hundred yards east of the landing slip where the ship *Bounty* was stripped of all usable cargo and material, and under orders from Fletcher Christian himself, set afire and sunk on January 23, 1790, only eight days after the mutineers landed.

Adamstown, the smallest British colony, and the original home of the mutineers, is situated on one of the few relatively flat areas of land on the whole island. It is here, some four hundred feet above sea level and about three hundred feet west of the bay, where all sixty-two inhabitants live, most of whom are also descendants of one of the nine mutineers who landed in 1790.

Shady Nook, a little area on the outer rim of the village, is where Tom, his wife Betty (also born on Pitcairn), and their three little girls call home. This is also the very same piece of real estate where Fletcher Christian and Mi'Mitti (Fletcher's Polynesian mate) made their first home some 187 years ago.

At one end of the Christian home in a small room is where the radio equipment is located for VR6TC. Most of the gear is from America, some of which was donated by the manufacturers several years ago.

Just outside of Tom's home is a 7 kW, 230 volt, single phase, 50 cycle diesel generator. This is Tom's and is used to supply electricity not only for the ham gear, but also the numerous appliances in the home when the community generator isn't in use.

The island had a 70 kVA, 230 volt, three phase, 50 cycle diesel generator, but something of an unknown nature happened and in June of '76, it went up in smoke

and thirty foot flames. A total loss. It has since been replaced with a smaller unit.

The community generator is only operated from sundown to 11 pm, and this leaves a big gap where no electricity is available. This is why Tom has his own generator and so helps keep VR6TC supplied with electricity.

I asked Tom one time what it costs for diesel fuel to run the generator. His answer sure made me appreciate fuel prices in the United States.

"We purchase diesel fuel in forty-four imperial gallon drums at a cost of $100 per barrel, plus $30 per barrel for shipping and $17 per barrel as a deposit. Fuel is expensive to obtain."

At $2.67 for each gallon of diesel (U.S. measurement), I wholeheartedly agree that electricity gets very expensive to produce on an island as remote as Pitcairn.

Tom's generator has been unreliable for quite some time and has had many problems. It isn't a complete unit but it is made up of parts from here and there. Belt-driven from a separate motor, the performance could stand much improvement.

Tom Christian VR6TC at his amateur radio station on Pitcairn Island, South Pacific. From here, in the past twenty years, Tom has made contact with nearly every country in the world. He is very well-known and one of the most popular operators on the airways; he is also one of the most friendly. The equipment is Hallicrafters: to the lower right is the driver and to the left is a linear. On top is the receiver. The two small units on top of the driver are a rotor indicator sitting on an electronic keyer. Tom very seldom uses the keyer. He says, "I like my straight key a lot better." VR6TC has three schedules each week with other operators in the States. "Calling up a fellow ham in the United States is almost as easy," Tom says, "as dialing a telephone."

Dr. Charles "Mert" Moser W6HS, a very close friend of Tom's, felt that the generator couldn't be relied upon to ensure VR6TC stayed on the air. With so many amateur radio operators around the world and Tom being the only operator on the island, something should be done to guarantee electricity to keep amateur radio alive on Pitcairn.

W6HS, through contributions, collected $2,500 and purchased a new generator for Tom. It is on the island now and has been installed. Contributions were sent in from all over the U.S. and some foreign countries, most of which were other amateur radio operators, but not all. Would you believe that amateur radio transmissions are monitored by the FCC? Well they are, and an FCC monitoring station sent a contribution for this generator fund. On behalf of VR6TC and all of amateur radio, we thank you.

A wind generator was sent to Pitcairn in 1975 to help charge a storage battery power supply that Tom purchased from Australia. The batteries supply electricity of 110 volts for electric lights and a few appliances that will operate from a dc source. The battery supply can't be used for the ham gear because all the equipment is wired for ac use only.

Tom told me one time that he has a 110 volt dc to 230 volt ac converter, but it isn't a reliable unit. He said that he will use it only in case of an emergency.

If something breaks down, and it does occasionally, you don't call a repairman. You fix it yourself. After all, the nearest repair service is over three thousand miles away, by sea. Tom has become very efficient, which is understandable, in the repair of both mechanical and electrical problems.

One morning VR6TC was almost thirty minutes late for a schedule. "My receiver was completely dead this morning," Tom said, "and it took a few minutes to locate and repair the problem."

Many of the homes on Pitcairn are connected by a telephone system so someone can be contacted if the need arises. This system was installed by the islanders as are all other equipment and services on the island.

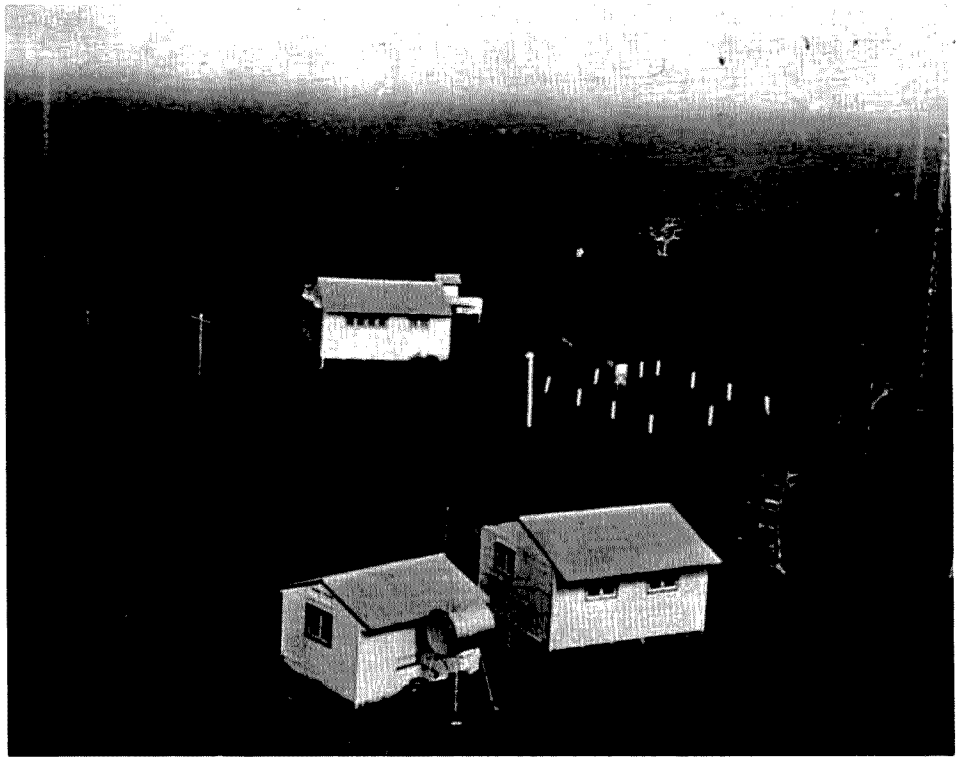
During a QSO one day, Tom received a phone call and was informed that the generator for the dispensary wouldn't start up. He left the air for less than an hour and then returned. All was OK; generator repaired.

If you happen to be listening to VR6TC and he suddenly goes off the air, grab a cup of coffee and QRX; he will be right back.

One time his sister Thelma, who lives next door, started up her washing machine and the circuit breaker kicked out on the generator. Tom was back on the air in short time. I guess amateur radio, at least this time, had priority.

Tom's VR6TC station is Hallicrafters equipment – a receiver, driver, and linear. Maximum output is 1 kW. Although the station is capable of more power, Tom said that he normally runs a maximum of five hundred Watts.

At one corner of Tom's home stands a forty foot wooden pole which has been cemented into the ground for support. Three feet above the



Pitcairn's radio station "ZBP" is situated at Taro Ground, 870 feet above sea level. Three of the seven steel 60 foot towers for the rhombic antenna system can be seen. The building in the foreground left houses the diesel generator which supplies electricity for the station. The building to the right is a storage shed. The one in the background is the station itself. The white markers to the right are the posts of the wire enclosure where the meteorological instruments are kept. The station is commercial and is operated six days each week by either Tom Christian or a staff member.

pole is a three element tri-band antenna. The system was put up about ten years ago. "The pole," Tom said, "has deteriorated so badly from the weather that it is unsafe to climb."

The antenna rotor indicator quit working and Tom has to stick his head out the window to see what direction the antenna is pointing. At night, he uses a flashlight.

Tri-Ex Tower Corporation heard about Tom's problem with the wooden pole and how unsafe it was, and they have very generously donated a new THD-354K, fifty-four foot crank-up tower to him. It should be arriving on Pitcairn any day.

Arrangements have also been made to ship a new rotor unit and tri-band antenna along with the tower unit. This will certainly ensure that VR6TC will remain on the air.

On March 23, 1955, Tom received his first amateur radio license in Wellington in the form of a New Zealand certificate. In 1957, exact date unknown by Tom, he received the VR6TC call for Pitcairn Island. Before Tom received even that first amateur radio license, he spent some time off the island.

For three years, Tom went to school in New Zealand, where he studied meteorology and radio communications technology. These studies enabled Tom to fulfill the requirements for the job he had held for the last twenty years: Pitcairn's Radio Officer. That schooling also earned Tom a 1st class radio telegraph operator's license for both coast and marine operation.

That 1st class license landed Tom a job with the Union Steamship Company for about a year. He worked as a radio officer aboard a passenger ship. While he was telling me this, he said, "While aboard one time during a run, the ship ran aground with about 450 passengers. Although no one was injured, it was quite an exciting moment."

I never did ask Tom how that accident happened, but I'm sure it was just one of those things that fate played a part in.

Upon return to Pitcairn, Tom was now qualified for setting up and maintaining the commercial radio station on the island.

Taro Ground, the location of "ZBP," Pitcairn's radio station, is a mile and a half from Adamstown by steep dirt road at an elevation of 870 feet. The equipment is British with a power output of around five hundred Watts. The large antenna system is of rhombic design situated on seven sixty foot steel towers. Tom maintains all equipment, which he also installed.

The radio station is under British authority with the administrative headquarters located in Auckland, New Zealand. Cablegrams, on an international basis, are received and transmitted on an average of one hundred per month. All traffic from "ZBP" is by CW mode.

Weather reports are transmitted twice daily. Ships at sea are contacted by radiotelephone from the marine radio equipment, also at the station. Any distress signals at sea can also be received here at this location.

"ZBP" is in contact with headquarters in Auckland each day. If a ship is scheduled to depart a certain country, which will later head for Pitcairn, Tom will be notified. In this way, the island people will know the approximate date of its arrival and can prepare to meet it. Sometimes, up to two months advance notice has been received.

Meteorological readings are taken on a regular schedule each day from a special area just outside the station building. The following are the results:

Annual rainfall is from 60 to 70 inches. Maximum summer temperature is around 86 degrees, with an average of 75. Minimum winter temperature is around 52, with an average of 64 degrees Fahrenheit.

That is typical South Pacific weather with ideal temperatures. The wind is generally mild, from 11 to 15 mph. Hurricanes are extremely rare, but have been experienced. I heard Tom recall a very windy day where a home had the roof blown completely off.

The radio station is maintained each day except Saturday (which is the Sabbath) by either Tom or one of his personally trained staff members. Since all traffic from the station is by CW, I was curious as to the code

speed requirement for the staff. Tom's reply was not only interesting, but informative as well:

"Most of the CW traffic by other operators is on an average of twenty words per minute. I require any person on the island who wishes to apply for a staff position to take a code test. The test will be for ten minutes at a speed of twenty-two words per minute. Only two mistakes are allowed during that ten minutes."

Six months ago, six British engineers arrived on the island for a special project in Bounty Bay. Their job was to extend the jetty in the bay out at least another thirty-three feet. This was done in an effort to make the entrance safer. The surf is treacherous and breaks relentlessly against the cliffs. Rocks were blasted out of the bay and large steel pilings were driven down in place. Rocks were then piled around them.

By the time you read this, the project will be done and Tom will have more time for amateur radio. His working on the bay project with the other men on the island has left very little time for ham contacts.

I know that a large number of operators have heard Tom, but never had a chance to make contact; some have never had the chance to even hear him. I asked Tom if a special day could be set up for publication and he agreed. VR6TC will be on the air for this special time as well as other times.

VR6TC is on every Tuesday at 2230 to 0100 GMT at 21.350 MHz. The *special* date is Sunday, April 10, 1977, at 1630 GMT at 14.300 MHz. It's possible that he may be on the following Sunday as well, but those mentioned are confirmed. Good luck.

The road from the village to Taro Ground and the radio station is long, steep, and a very tiring walk. Tom, in 1966, purchased and introduced the very first motorbike on Pitcairn. Now the trip is made with greater ease and speed on those twice daily schedules. Betty also has a motorbike. In fact, there are almost forty of them putting around on the island, as well as two Mini Moke cars. Why walk when you can ride, even on an island as small as Pitcairn.

Tom and Betty, a few years ago, took off on the motorbikes to go fishing. It was a nice clear day, but before they could get back, a rainstorm began. The dirt roads turned to gooey red mud and on the way back an accident occurred.

People on Pitcairn are no different than you or I and sometimes go barefoot. On this day, Tom was barefoot and the bike slipped in the mud and his toe got caught in the spinning chain. The rest you can visualize: Tom is now missing half of one big toe.

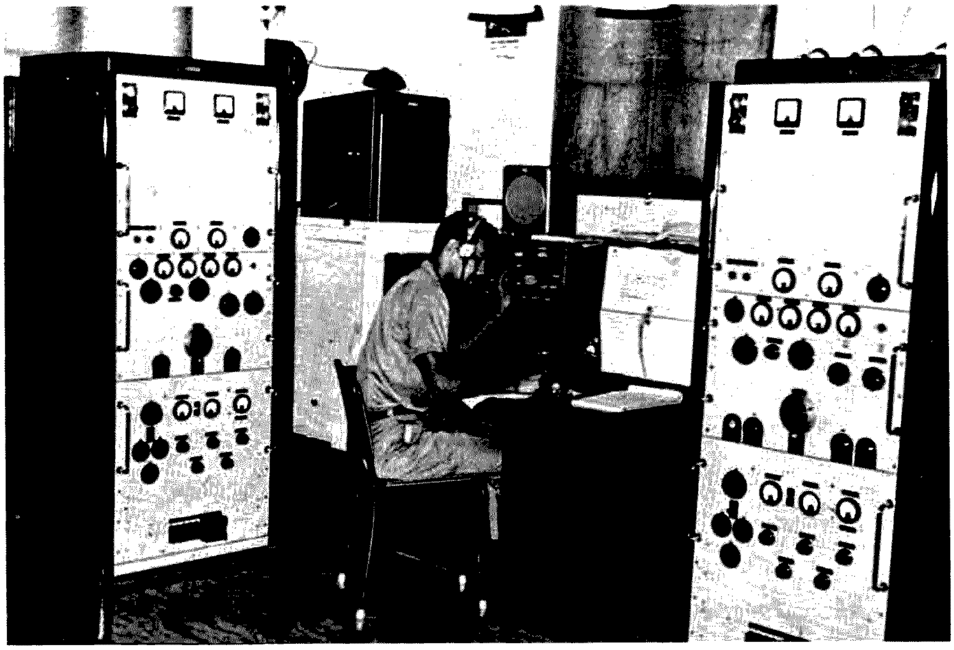
Probably the most feared ailment anyone on the island could encounter is appendicitis. While Tom was in New Zealand, one of his two sisters had an attack of appendicitis and a ship at sea was contacted by radio. Before the ship could get her to New Zealand, she died. "It was quite a shock when word reached me." Tom told me about this not too long ago. What he didn't tell me was that he too had been stricken. I found out during my research for this article.

One day on the island several years ago, Tom too had that terrible pain in his side and he knew exactly what it was. Every household turned its refrigerators up to the maximum setting and made as much ice as possible. Tom was packed in the ice and a ship was contacted from the radio station. The ship arrived, but had no doctor. Tom was taken aboard and kept in ice for the eight day trip to New Zealand. He was one of the few who were fortunate enough to survive. The world of communications again had been needed and proved to be an appreciated treasure.

In the year 1967, one year after Tom and Betty were married, they both came to the United States, where, for about eight months, they were residents of California.

Tom had come here to further his training in radio communications at the Voice of Prophecy, international radio broadcast center of the Seventh-day Adventist Church, located in Glendale CA.

Here he met Eddie Pullen WA6ECC, chief engineer for the VOP and operator of the ARC station K6DTT. VR6TC and K6DTT are in contact each week via amateur radio and these two friends exchange events of here and there. Eddie Pullen also helps Tom and the people of Pitcairn when certain items are needed on the island. With no department store on the island, it takes a long time to get much needed items. Amateur radio reduces that waiting time to half.



Tom Christian on duty operating Pitcairn's radio station "ZBP." The equipment is British with a power output of about five hundred Watts. Tom operates, maintains, and installed the station. Two daily overseas schedules are kept with Auckland, New Zealand. Cablegrams on an international basis are received and transmitted on an average of one hundred per month. The marine radio, also at the station, is used to contact ships at sea, some of which stop at Pitcairn. All traffic from "ZBP" is by CW mode. Tom and Betty both have a code speed of twenty-five words per minute.

Tom also met Dr. Moser W6HS, who so generously set up the fund for the previously mentioned generator. Dr. Moser, called "Mert" by everyone, is a PhD professor at the University of Southern California. Tom and Betty were house guests of Dr. and Mrs. Moser for several weeks. VR6TC and W6HS also have a weekly schedule via amateur radio, now that Tom is back on the island. Dr. Moser on many occasions had made medical *housecalls* for Pitcairn via amateur radio. One of them will be mentioned a little later.

While Tom was in the States, he did a personal appearance tour with the MGM movie, "Mutiny on the *Bounty*." He also appeared on the TV show "To Tell the Truth." Not one of the four panelists guessed that he was the real Tom Christian, descendant of Fletcher Christian of *HMS Bounty* fame.

Tom has relatives in New Zealand, Australia, Norfolk Island, the state of Washington and, of all unlikely places, my home QTH.

For more than two weeks, Tom and Betty stayed at Tom's cousin's home in Porterville CA. Three-quarters of a million amateur radio operators around the world would jump at the chance for a face to face QSO with Tom and here he was, only six blocks away from me, and I didn't even know it. You can't win 'em all.

I had a schedule with VR6TC about two weeks after I found out about the above. During the schedule, Tom's cousin, Beverly Lowe, and her husband Harry had a ten year reunion with Tom and Betty Christian, thanks to amateur radio. It really is a small world when amateur radio gets involved.

Although VR6TC is the only license issued to a member of the Christian family, there were others who operated from Pitcairn before Tom. Floyd McCoy VR6AC and Andrew Young VR6AY both operated from Pitcairn over thirty years ago. Some of you old-timers may have a QSL card from one of these hams, both of whom are also descendants of the *Bounty* mutineers.

More than 20,000 QSL cards have been mailed from Pitcairn with VR6TC imprinted on them destined for every corner of the world. If you made contact with VR6TC, sent a card but never received an exchange, there could be a definite reason.

Pilferage of mail has been known to occur with letters and packages sent to and from Pitcairn. Certain items which Tom knows were sent never reached their destination. Where they went astray is anyone's guess. For any QSL card that Tom received – if he has it confirmed – a VR6TC card will be or has been sent in exchange.

Remember, Pitcairn is a distant and very isolated island and the shipping to and from there is on a one to two month basis, sometimes longer. The mail will pass through several hands before its final destination is reached.

If the weather is bad, ships have been known to bypass the island, even when they carried much needed supplies for the island, including mail. This means that it could take several more months before that mail is finally delivered and the mail on the island is picked up. Several years ago, an incident occurred which was responsible for the loss of many QSL cards leaving the island for their worldwide distribution.

The only entrance and exit for Pitcairn is from Bounty Bay in one of the island's 38 foot long, 9 foot wide diesel-powered whaler type longboats which are built on the island. They are capable of carrying up to 5 tons of cargo and are the only method the people have of getting out to the ships for transfer of cargo and mail.

On June 23, 1972, one of the longboats attempted to take a supply of mail out to a waiting ship and pick up cargo for the island. The seas were violent and the longboat was caught by a large wave and capsized, spilling all the men overboard, and also the mail. Half of those men were injured. The most serious was Tom; the boat had landed on top of him.

"I almost lost my life but managed to make it to the rocks. From there," Tom said, "I crawled toward the landing. My right leg had been broken and the left one was severely bruised."

Tom clung to those rocks for a half hour before anyone could get to him for rescue. He was taken to the island dispensary and the leg was set. A few months later, when the leg didn't heal properly, he went to New Zealand and into a hospital; the leg had to be broken again and reset.

The cargo of mail which spilled overboard when the accident happened contained a large number of QSL cards; they sank to the bottom of the bay.

If by chance you had sent Tom a QSL card prior to that date and never received one in return, yours may have been one lost at sea. Send another one; I'm sure Tom will be very happy to reciprocate, again.

"QSL information is Tom Christian, Box 1, Pitcairn Island, South Pacific." Tom has given that VR6TC contact information a thousand times over. When he gives it to you, a few tips will get a QSL card back a little faster. The envelope will also have a very rare Pitcairn stamp on it.

The U.S. Postal Service now charges 42 cents for a single IRC. One of them is worth only 10 cents on Pitcairn. It costs Tom 35 cents to mail your card back to you. That means you would have to spend $1.68 for IRCs to help Tom pay some of the postage. Save some money and slip a single dollar bill into an envelope with your QSL card and a self-addressed return envelope. That little extra change will help Tom to defray some of those expensive fuel costs to produce electricity for amateur radio's VR6TC. I'm sure he would appreciate the kindness and you will save, also.

When you mail everything, be sure to use a dark colored envelope so the contents can't be seen. Send it *air mail*. This way it will be flown to either the Canal Zone or New Zealand, the only pick-up points for mail going to Pitcairn. If sent by surface, it will wait in some port for the next ship going to one of those two locations. That could cause an additional delay of several months.

The engineers on the bay project took a special survey at the request of an unknown company in Tahiti. It was to determine the possibility of constructing an airstrip of about 900 meters (2,952 feet) on the island. As Tom put it, "It would require the moving of mountains." He did say that it was possible for a 600 meter runway, but no further information was available. Someday it might just be a few weeks before an exchange of QSL cards is possible instead of the current time of up to six months.

Tom and Betty Christian have three girls: Jacqueline Beth, born January 8, 1971, Raelene Kari, born January 28, 1974, and Sherileen Teresa, born December 1, 1975; all are on Pitcairn.

Tom has been asked several times when he will come to the U.S. again. His answer is almost always, "With Betty and the small children, it would be very difficult to get away."

Tom is under contract to operate station "ZBP," but has been heard several times to say that he isn't sure he wants to sign another 3 year contract. Just before Christmas I asked him what the possibility was of him coming here again. This was his answer: "A new contract would compel me to stay here on the island, but I'm

Tom and Betty Christian amongst the numerous tropical fruits which grow in abundance on Pitcairn Island. Tom is holding a breadfruit, the plant which in turn brought about the existence of the descendants of mutiny and the people of Pitcairn Island.

not sure if I want to be tied down. If possible, I may go on a trip of about 6 months starting in June of '77. Very much thought is on visiting the States again, soon."

I would be wrong if I attempted to say that Tom *will* come to the States. Only time and Tom himself can do that.

"Amateur radio is a break from the normal life and a chance to sit down, relax, and talk to friends in other parts of the world." Those are Tom's words and feelings in conversation one day. Public service also gets involved, especially on an island as small and isolated as Pitcairn.

We take for granted the medical services available to us, since we live in a country where a hospital and doctor are always close at hand. On Pitcairn, there is no hospital or doctor, only a small medical dispensary.

It is a requirement that the wife of the Seventh-Day Adventist pastor (who serves a two year tour of duty on the island) be a registered nurse. She is the medical officer for the island. Her qualifications are excellent, but sometimes an illness can reach into the field of an M.D.

On Thursday this past August 12th on 14.225 MHz, I was waiting for VR6TC to come on frequency for his regular schedule with W6HS. It was almost 15 minutes before Tom was due at 1600 GMT when I heard VR6TC call for W6HS; no answer. Another station answered and I heard Tom state that he was calling early because of a possible emergency on the island. Pastor Newman was very sick with a temperature of 104 degrees and had been this way for several days.

Since W6HS was still not on frequency, I gave him a long distance phone call and told him of the above. He got on the air immediately.

After a short discussion between Tom and Dr. Moser, a colleague of Dr. Moser's was contacted who specializes in respiratory diseases. A phone patch connection was provided by John Stagnard W6MAB for Dr. Dickson Young, Beverly Hills CA. The results were a 4,500 mile housecall via amateur radio.

Dr. Young talked to Tom and the nurse on the island for several minutes. They explained Pastor Newman's symptoms and what medication had been administered.

Diagnosis: viral pneumonia. Recommendations were made for additional medication from what was available in the island dispensary. The following week I heard Tom say that Pastor Newman was very much improved and could now get out of bed for extended periods of time. Today, Pastor Newman is in New Zealand and is very healthy.

Pitcairn Island is a unit unto itself, isolated by a stretch of empty sea. Amateur radio is a vital link to the outside world and plays an important part in the lives of every person on the island. Without amateur radio . . . ■

EDITORIAL BY WAYNE GREEN

from page 22

CBers into the hobby which reversed the ten year license downward trend.

Few authors like to have their articles rewritten by magazine staffers, particularly when major changes are made. Other than correcting grammar and spelling errors, *73* publishes just about all articles as they come from the authors . . . and in this respect *73* seems to be unique in the field.

Few of us are wealthy enough so we can afford to flat give away the enormous amount of time and work (not to mention the expense of photographs) that it takes to prepare an article for publication . . . plus later proofreading of galleys and then answering of reader questions. While most articles pay only about $100 to $300, this still takes a lot of the sting out. And it is the amateur who benefits from adequate author pay in the long run, for paid authors tend to keep writing, and unpaid ones tend to find better things to do.

Right now microprocessors are of high interest to *73* readers, but what will be next? *73* called the turn on SSB, on RTTY, on SSTV, on transistors and ICs, so keep watching: Whatever it is, it will be in *73* first.

As an author, then, you are interested in placing your article where it will get the best readership, where you'll get the most money for it, and where it won't get mangled by some "editor" who doesn't really understand what you've written. How do the four ham magazines shape up in these respects?

On the payment end of things, we seem to have *73* on one end, paying the highest dollar for articles . . . and paying upon acceptance (which means right away). The other magazines range from somewhat less pay, to very little and wait a year or so, down to no pay whatever.

Readership? You probably have this figured out . . . one magazine is aimed mostly at contesters . . . another at engineers . . . and one seems to be largely going to libraries these days. *73* has been reaching both the active old-timers and the newcomers . . . it's where the action is.

How Do You Use ICs?

-- part VI

Alexander MacLean WA2SUT/NNN0ZVB
18 Indian Spring Trail
Denville NJ 07834

Before leaving the wonderful world of counter displays, there are several other ICs which you should know about. Not that they are especially useful, but they sound as if they were, and you might be able to use them.

Specifically, there is the SN7492 divide-by-twelve counter and the SN7493 4-bit binary counter. They don't really sound promising, but they must have been built for something.

The first looks the most promising, as if it remotely had something to do with time, and the other is just there. However, for a reason which will become obvious, we will start with the second.

Before plunging in, review Fig. 1. This is the schematic of one counting digit using the SN7490 decade counter. This test circuit will count from one to ten (zero).

In particular, notice the A, B, C, and D outputs and how they connect to the SN7446 decoder/driver. The pin connections for the SN7493 are exactly the same as for the SN7490 (except there is no nine reset circuit), so you can just substitute one for the other with no changes. Now you see why it comes first.

But what does it do? With this hookup it counts to 16. This will take a bit of explaining. The first thing you want to know is how to count up to 16 with just one digit. It can be done. It's weird, but it can be done.

The key to understanding actually lies in the decoder/driver and the readout IC. In most applications, the decoder/driver is only called upon to count up to ten, but the circuitry is built in to decode up to 16 pulses. The next problem is how do you display a count of 16 on a seven-segment readout designed for zero through nine count?

There is a very simple answer. You cheat. If you look at Fig. 2 you will see how it is done. They simply chose arbitrary combinations of segments for the additional figures. One of the combinations blanks out the readout on that count. You have to be watching for it or you will miss it.

There does not appear to be any normal type of device that uses this feature in amateur use. It appears to be used for some data instrumentation purpose rather than a specific counting purpose.

The SN7492 divide-by-twelve counter sounds like it might be related to a 12 hour type of thinking. It is, but not directly.

Notice in Fig. 3 that the pin connections for the 7492 are not the same as for the other two ICs. The B, C, and D outputs are not the same pin numbers. Apart from these changes, the circuit is the same for the rest of the test circuit.

When in place, the inclination would be to assume that it would count from 1 to 12 in the same manner as the 7493 counted from 1 to 16. Not so.

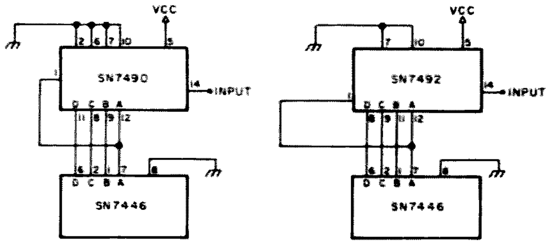

Fig. 3. Note A, B, C, and D pin connection differences.

To understand this, refer to the logic tables in Fig. 4. This is the table of the coded output for each number of pulses that gets fed to the decoder/driver.

Notice that they are all the same from zero to five, but after that they are not the same. If you try to go past five in the count sequence with the 7492, you will not get six. So much for its ability to count.

The reason lies in the truth tables. Notice that the output codes for the 7490 and the 7493 are in binary code, the same as they would be written out. They are both binary counters.

The 7492 is not. Its output follows the binary code up to five and ceases to be binary after that. If you look at the table, you will see that six has the binary code of eight, seven has the code of nine, and so forth.

After nine, it goes into the arbitrary segment selections for the higher numbers. This still follows the binary coding, but with the break in the middle, the continuity is lost.

So what can you do with it? Getting back to time, there is an obvious answer. To count seconds, you go from one to ten (zero), but when you get to tens, it goes 57, 58, 59 seconds, one minute. In other words, from zero to five. This is six counts.

The 7492 is also a divide-by-six counter. The trick is to make it reset to zero after the fifth count. This is easy once you know how.

Look at the truth table again. Notice that the output at six is exactly the same as for zero except for the D output. Also notice that the D output does not appear in any of the sequences from zero to five. Therefore, we can do without the D output.

To do this, we lift the D output from the 7492 counter and leave it floating. Then ground the D input pin of the decoder/driver. Now the circuit will count from zero to five.

One obvious application would be to cascade units to get a seconds and minutes readout for an elapsed time counter circuit. This gets you into reset circuits a little more deeply.

Resetting is usually done with logic levels, but in a simple circuit like this one, it's done by grounding (0 or low logic) or ungrounding (1 or high logic) the correct pins.

With the 7492, both reset pins must be high (1) to reset to zero. At least one of the reset pins must be at low (0 or grounded) to count.

With the 7490, there are two sets of reset pins. To reset to zero, both zero reset pins must be at logic 1 (high), and at least one of the nine reset pins must be at logic 0 (grounded)). For proper counting, at least one of each set's reset pins must be at logic 0 (low or grounded). The 7493 is the same except there are no nine reset pins.

This is mostly done for you on the published schematics, but when you roll your own, you may forget to see that those pins are accounted for.

One of the first things to look for when you don't get proper counting action is an error in the basic hookup or the incorrect use of the reset pins.

These gadgets are designed to be compatible, so there is no real problem when cascading them to get a timing readout. Two digits are shown in Fig. 5. Except for the obvious changes in wiring for the two different counter ICs, the circuit is the same as for the regular readout.

The external circuitry would be very similar to what a counter would use. In a simple setup like this, there would be a timing chain derived from the ac line frequency, a gating circuit to start and stop the count, and a reset circuit.

External to the unit would be some method of keying the elapsed time counter mechanically or electronically. Something must tell it when to start and when to stop. There are a wide variety of switching methods depending upon the application.

Still, this is similar to the frequency counter application, and may in fact be somewhat simpler. However, neither of these counter ICs has found wide application in amateur counting circuits. They are, however, familiar in frequency dividing circuits.

Just as the 7490, the 7492 and the 7493 have both been used to get different frequency divisions. This usage was covered in a previous article.

If you have a few of these ICs on hand for frequency dividing, you might try them in this test circuit so that you will know how they behave. Then when you run across them in an application you want, they will not be unfamiliar to you. ■

Super Low Voltage Power Supply

- - with overcurrent protection

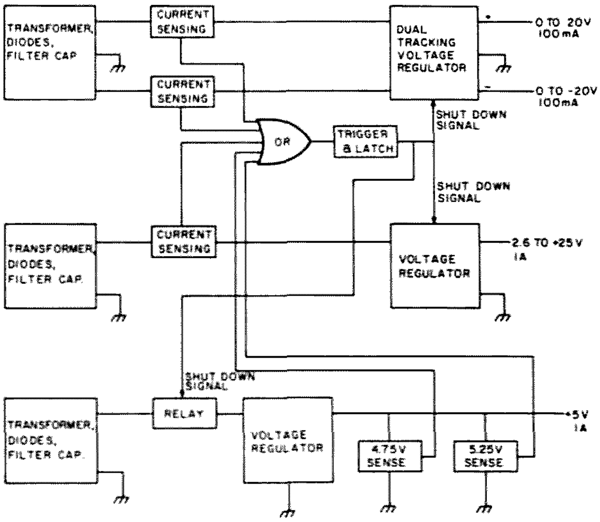

Fig. 1. Basic layout.

Thomas E. Hutchinson VE3CWY
35 Warrender Ave., Apt. 208
Islington, Ontario
Canada M9B 5Z5

The following article was prompted by the many disasters I have had while experimenting with unfamiliar ICs and untested circuit designs. This past year I have destroyed two TRV2000 voltage regulators, one XR205 function generator, two 741 op amps, two 709 op amps, one optical isolator, and so on. Sometimes it happens when the meter probe slips and sometimes it happens because of incorrect design of the circuit. In nearly all cases, however, things burn out because of excessive current drawn for too long a time. The remedy is a power supply that abruptly removes the voltage from the circuit once a preset current is exceeded. I felt this would be superior to the usual type of current limiting in which the power supply delivers a constant current to the load and less voltage once the current limit is reached; the objection to the latter is that the user may not be aware that the current limit has been reached and that the voltage is no longer regulated, especially if it happens for only a very brief interval. A circuit may not operate correctly with the unregulated voltage during this interval and the user would be hard pressed to discover the reason for the malfunction.

Basic Layout

Three power supplies were constructed as shown in Fig. 1. The first is a dual tracking supply with variable output voltage 0 to ±20 volts and current to 100 mA on each output (200 mA total current capacity). Also available is a +12, -6 volt option. Current sensing is done in both the positive and negative legs, and when the current exceeds a preset level, a signal is developed to shut down the output from the voltage regulator. This signal latches so that output voltage can only be restored by pressing a reset switch.

The second supply has variable output from 2.6 to 25 volts and current to 1 Ampere. Up to 34 volts is available at reduced current. This supply also has adjustable current sensing and, like the first supply, the output voltage shuts down when the current exceeds a preset level. Voltage is restored by pressing the reset switch.

The third supply provides a fixed 5 volt output at currents to 1 Ampere for operat-

ing TTL circuits. This supply has output voltage sensing and will shut down if the voltage moves outside a preset range from 4.75 to 5.25 volts.

The first supply provides the power for the sensing circuits used in all three supplies. Also, if any one supply shuts down, the other two will shut down also.

All three supplies use voltage regulators that are short circuitproof, an added safety bonus in the event that the current sensing circuits are manually disabled or in the event of the failure of some component in the current sensing networks.

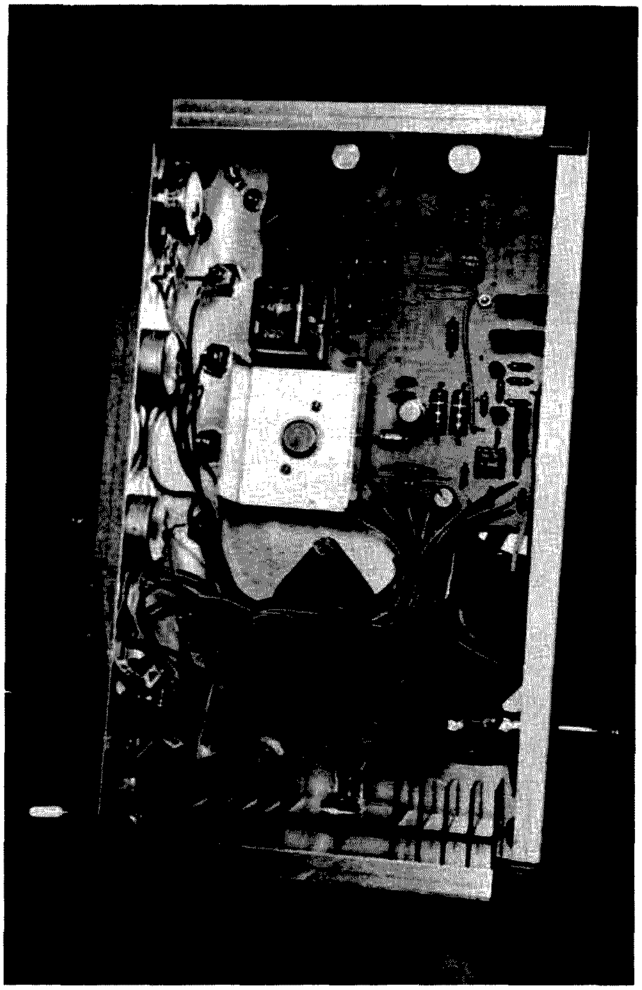
Current Sensing

The current sensing network in Fig. 2 operates as follows: Assume that initially no current is drawn from the supply. With R2 set to 500Ω, R2 + R3 = 21k and R4 + R5 = 21k. With the wiper of R4 set closest to R3, the voltage at pin 11 of voltage comparator IC1A will be 14 volts, exactly half the voltage across C1. Assuming for the moment that no current flows in R1, the voltage across R6 and R7 will be 28 volts and the voltage at pin 10 of IC1A will be 14 volts also. When current is drawn from the positive leg of the supply, a voltage drop develops across R1 and the voltage at pin 10 of IC1A drops below 14 volts. This drives pin 13 of IC1A positive and the resulting current in R21 charges C3. Q1 fires, sending a pulse through C4 to SCR1. SCR1 turns on, operating relay K1 and forcing Q2 to switch on. Q2 shorts out R27, thus reducing the output of IC3 to nearly zero volts. K1 interrupts the current to IC6 in Fig. 3. Q1 also sends a pulse to C14 in Fig. 3. This pulse turns on SCR2, forcing Q4 to switch on; this action reduces the output of IC5 to zero volts.

When the load is removed from the output of IC3, the power can be restored by opening S2A and S2B (normally closed switches). By moving the wiper of R4 closer to R5, the voltage at pin 11 of IC1A is lowered. It then requires a greater voltage drop across R1 (more current in the load at output of IC3) to lower the voltage at pin 10 of IC1A so that pin 13 will go positive. Thus the setting of the wiper of R4 determines what current will drive pin 13 of IC1A high.

An identical network consisting of R8 to R14 and IC2 senses the current in the negative leg of the supply. The output of IC2 switches between 0 volts and -26 volts approximately. Since IC1B will not operate normally with any input below -0.3 volts, the voltage from pin 6 of IC2 is divided down by R15 and R17 so that the voltage across R17 switches between 0 volts and -0.25 volts. R16 and R18 form another voltage divider which provides -0.15 volts to pin 8 of IC1B. Thus IC1B switches like IC1A in response to an overcurrent in R14. D5 and D6 form an OR gate, hence isolating the outputs of IC1A and IC1B from one another.

In Fig. 3, current sensing is done in the same manner as described for the positive leg of Fig. 2. Since the maximum current for this supply is 10 times greater than for the first supply, resistance values have been adjusted according-



Bottom view of power supply.

In all diagrams, all resistors are ¼ W, except as otherwise noted. All capacitors are in uF.

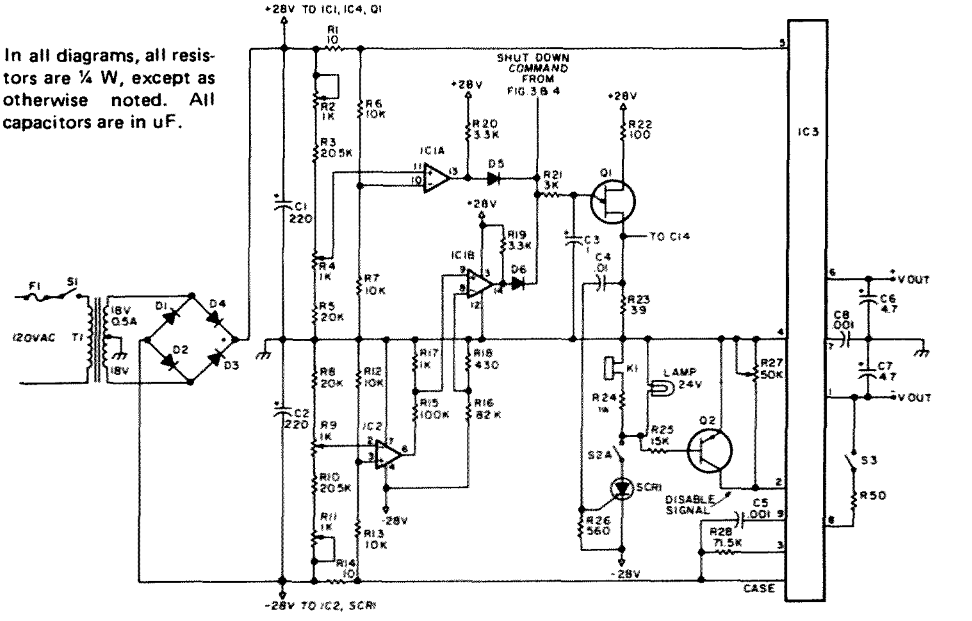


Fig. 2. Dual tracking regulated supply.

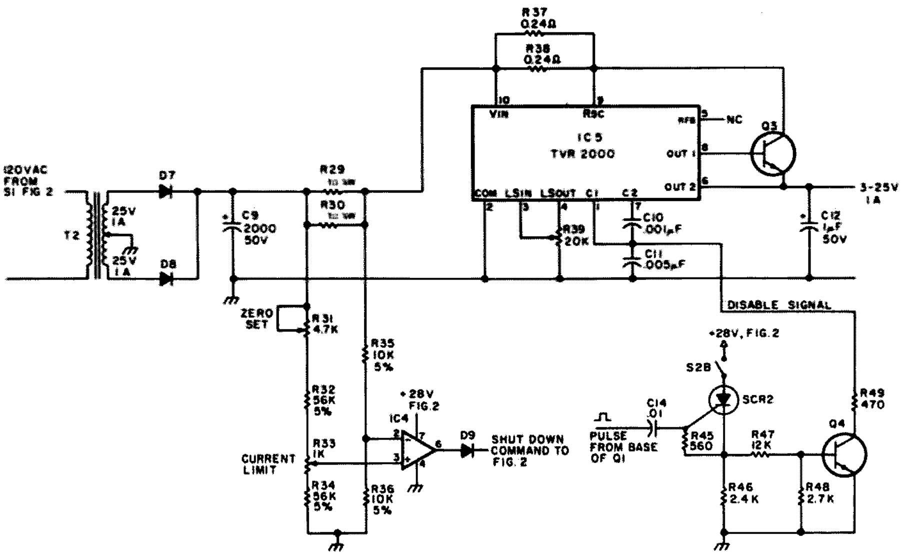

Fig. 3. Variable voltage power supply.

ly. D9 forms another part of the OR gate that feeds R21.

Voltage Sensing

For the 5 volt supply in Fig. 4, it is more desirable to have output voltage sensing than current sensing. This is because there are wide variations in the current demanded by TTL circuits when they are switching from state to state. The current limit point would always have to be set rather high, and consequently only gross overcurrents could be sensed. On the other hand, a circuit that senses when the voltage falls below 4.75 volts, the lower operating limit for 7400 series TTL, is quite useful. Suppose, for example, that you are operating near the 1 Ampere limit of IC6; a brief current pulse could exceed this limit and the internal circuit of IC6 would then allow the output voltage to drop. Without voltage sensing this could easily go unnoticed and your circuit would malfunction.

In Fig. 4, D14 provides a reference voltage. R41 acts as a voltage divider and is set to 5.25 volts. R42 is another voltage divider and is set to 4.75 volts. IC1C and IC1D compare the output of IC6 to these voltages and, if the output moves outside the window from 4.75 to 5.25 volts, pin 1 or pin 2 will go high. This signal goes to R21 of Fig. 2 and eventually shuts down all the supplies.

Response Time

R21 and C3 determine the response time of the circuit. With R21 = 3k and C3 = 1 uF, the circuit responds to an overcurrent, overvoltage or undervoltage that lasts 3 milliseconds or more. K1 adds an additional 7.5 ms to the time required for the 5 volt supply to shut down. By reducing C3 to 0.1 uF, response time can be made as low as 0.3 ms. R21 can be increased to as much as 10 megohms if desired to lengthen the response time, but should not be reduced below 3k.

The Voltage Regulators

The 4194TK regulator is available through advertisers in this magazine. It is internally current limited at about 350 mA when the positive output is shorted to ground. It also has internal thermal limiting that will reduce the output when it gets too hot. A small heat sink is required when the operating current is 100 mA in each leg of the output. In Fig. 2, S3 is normally open. When S3 is closed, R27 can be adjusted to give +12, -6 volts output for the operation of certain types of voltage comparators.

The 309K also has current limiting and thermal limiting. It will provide a little over 1 Ampere when mounted on a heat sink with the circuit shown.

The TVR2000 has been available from Poly Paks for a number of years and is quite inexpensive. It is surprising that in spite of its outstanding performance and low cost I have never once seen it used in a magazine article. Perhaps it is because the information on how to use it is hard to find; the specification sheets that come with it do not give enough information on how to use it. A very complete article on its use in a wide variety of applications can be found in the periodical called *EEE* (Electronic Equipment Engineering), Volume 17, No. 6, June, 1969, pages 82 to 90, available at large libraries. The name of the article is "Voltage-Regulator ICs with Foldback Current Limiting," by D.R. Sullivan and H.W. Mamie.

In Fig. 3, the foldback current limiting option is not used. Instead, simple short circuit sensing is used. R37

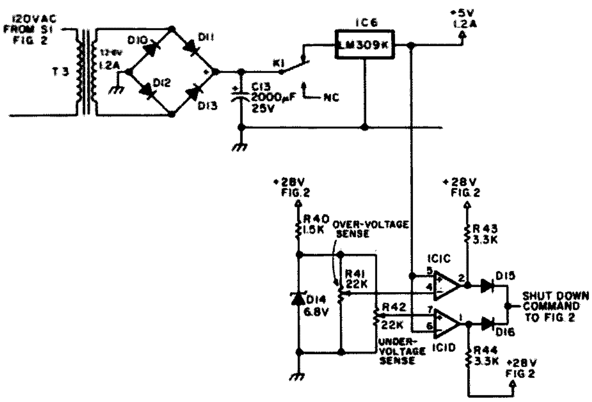

Fig. 4. 5 volt power supply.

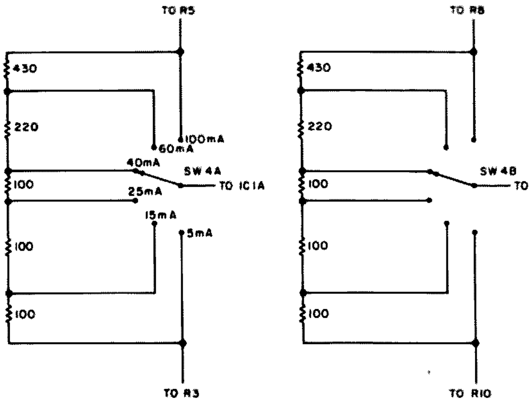

Fig. 5. Switch selected resistors replace R4 and R9.

and R38 set the short circuit current to a value of about 1.2 Amperes. The relationship here is $R_{SC} \cdot I_{out} \approx 0.1$ volt, where R37 and R38 in parallel make up R_{SC}. R39 sets the output voltage. Q3 acts as a current booster and is mounted on a heat sink. C10 stabilizes the current limiting circuitry and C11 stabilizes the regulator section of IC5. Different values from those shown may be required to drive high capacitance loads.

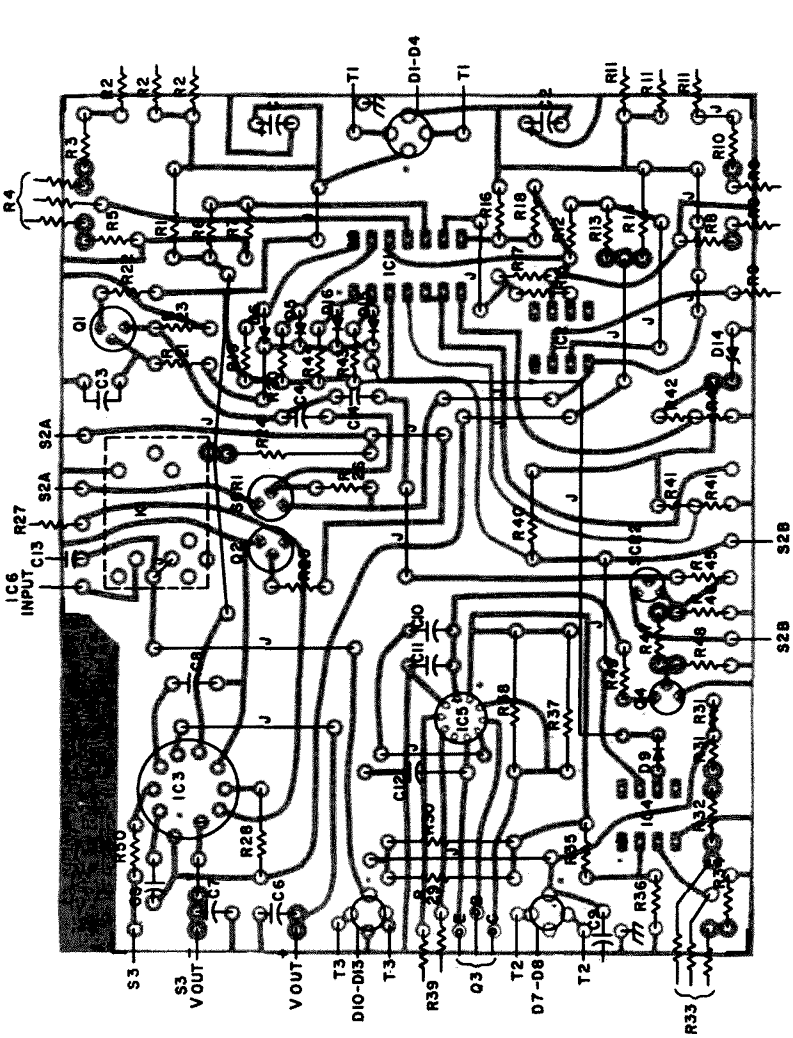

Fig. 6. Parts layout.

Selecting Resistors

Resistors of 1% tolerance are best for R1, R3, R5 to R8, R10, and R12 to R14. This will make the final adjustments simpler and will keep tracking errors in R4 and R9 to a minimum. In Fig. 3, 5% resistors will suffice for R32, R34, R35, and R36, providing you choose them such that R32 ≤ R34 and R36 ≥ R25.

Regarding the tracking of R4 and R9: Since they form a tandem control, it is important that they both exhibit approximately the same resistance between their wipers and their ends for all rotations of the shaft. Failure to do so will mean that the positive and negative legs of the supply will trip at different currents. Several dual controls I bought did not track very well. If you want very good tracking, replace both R4 and R9 with a series of 5% resistors and use a two pole rotary switch to select the current limit you want as shown in Fig. 5.

Construction

All three supplies were constructed on a single 4" x 5" printed circuit board as shown in Figs. 6 and 7. IC3 does not plug directly into the board; the holes in the board have been spaced out to assure clean etching. Solder a short wire to the outside of each pin of IC3; insert the wires into the PC board and solder. A piece of aluminum was bolted to IC3 as a heat sink. There are so many connections to the PC board from the external switches, controls, transformers, etc., that it was not possible to arrange for an edge connector on a board of this size; instead there are about 35 wires soldered at various points around the edge of the board and all are routed to one end of the board so that the board can be hinged outward from the chassis if parts on it need to be replaced in the future.

All components fit nicely on a chassis 10" x 6" x 2" as shown in the photograph.

Final Adjustments

Switch S2 to reset. Leave S3 open. This disables the shutdown mechanism. Connect a high impedance voltmeter between pin 7 of IC1D and ground. Adjust R42 for a reading of 4.75 volts. Connect the voltmeter between pin 4 of IC1C and ground. Adjust R41 for a reading of 5.25 volts.

Set the wiper of R33 to the end closest to R32. Connect a voltmeter between pin 6 of IC4 and ground. Adjust R31 so that the reading just goes to zero.

If you are using a dual potentiometer for R4 and R9, proceed as follows: Set the wiper of R4 to the end closest to R3; the wiper of

Partial Parts List

SCORING:

U.S. and VE contacts count one point, while DX contacts count 3 points for Wisconsin stations. All others score 1 point per Wisconsin contact. Wisconsin stations are to multiply the total QSO points by the number of ARRL sections and Wisconsin counties contacted (146 max.). KP4, KH6, KL7 and KZ5 count both as 3 point QSOs and as section multipliers. All non-Wisconsin stations should multiply the number of Wisconsin QSOs by the number of Wisconsin counties worked (72 max.). Multi-county portable/mobile operations will keep a single log for the entire operation and will multiply the contact points by the total number of different sections and counties worked.

AWARDS:

Certificates will be awarded to the high scoring fixed, portable, mobile, Novice and VHF stations, in Wisconsin as well as each ARRL section and each DX country. The Neenah-Menasha Club is sponsoring a magnificent traveling trophy to be awarded to the high scoring Wisconsin entry of a club each year. This trophy will be awarded to the club submitting the highest total combined score of its members.

ENTRIES:

A summary sheet and station log are requested. Indicate each multiplier the first time worked. Logs must be received no later than May 6, 1977 (DX logs by May 20). Wisconsin clubs should forward a letter stating the calls of their members whose score counts for their club's total. Club members should be sure to identify their club on the first page of the log submitted. All entries should be addressed to: Kenneth A. Ebneter K9GSC, 822 Wauona Trail, Portage WI 53901. Enclose a business size SASE for notification of results.

1977 MASSACHUSETTS QSO PARTY

Starts: 1200 UTC, May 14
Ends: 2200 UTC, May 15

The contest is sponsored by the South Shore Repeater Assoc., Weymouth MA. No time limit. A station may be worked once per band, CW and phone considered separate bands. No crossband or repeater QSOs permitted. Mass. stations may work each other.

EXCHANGE:

RS(T) and county (for Mass.) and ARRL section (or country) for others.

SCORING:

Count two points for each completed exchange. Outside stations multiply total QSO points by different Mass. counties worked (total: 14). Mass. stations multiply total QSO points by different Mass. counties plus ARRL sections and DXCC countries worked. (Do not include E. Mass. or W. Mass. as sections.)

FREQUENCIES:

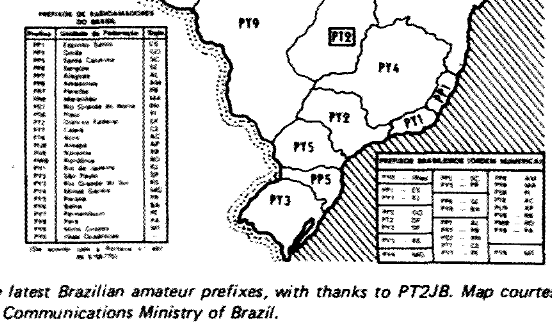
CW – 1810, 3560, 7060, 14060, 21060, 28060.

Phone – 1820, 3960, 7260, 14290, 21390, 28590, 50.110, 146.52.

Novices – 3720, 7120, 21120, 28120.

AWARDS:

Suitable awards. Mailing deadline, June 30. SASE for results and awards, c/o R. J. Doherty W1GDB, RFD #1, 14 Pine St., Sandwich MA 02563.



The latest Brazilian amateur prefixes, with thanks to PT2JB. Map courtesy of the Communications Ministry of Brazil.

QLF? Not with the Great Lakes Sideswiper!

-- almost perfect CW

With no apologies due the electronic keyers and the modern keyboard or "CW" typewriters, a telegrapher's "fist" is as individual as handwriting. We observe this, of course, by listening to the other guy.

It can be a pleasure to listen to some hand keying, or it may be almost impossible. For instance, how often do we hear persons sending things like, "My nag is Bobbob"? The Lone Ranger's nag is "Silver." We should remember this the next time we send letters in words that need accurate spacing. This used to be called QSC, meaning "your spacing is bad." The OBCQS, or Official Board for Changing Q Signals, replaced this with QSD for some obscure reason. Still, QSD is one of the rarest and littlest used of all the Q signals.

While on the subject of the OBCQS, someone of course had to take over eventually! Think of conditions that used to exist. When you heard the signal QRL immediately followed by twenty of the abbreviations for "I understand," it was reasonable to assume that the station sending all that was busy. They simply removed the 20 "I understands."[1] See how logical the work of this secret board turned out to be? Now we have just QRL, meaning "I am busy," though inferred is the added information, "Please QRT or QSY or turn your receiver on before clobbering my QSO." I hope the OBCQS has been disbanded for malfeasance, as it loused up a number of things (like "QSB"), so nowadays you have to spell it out to find if your spark is bad.

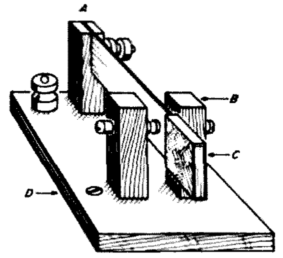

Fig. 1. A: Support for the blade and paddle. B: Posts (parallel connected, or for electronic bug, a terminal for each post). Distance from A to contacts on blade and posts is 2½" (6.3 cm). C: Paddle, to overhang front edge of base D about ½" (1.25 cm). Distance from front end of C to contacts is approximately 2" (5 cm). Dimensions of C, approximately ¼" x 1" x 1¼" (0.6 cm x 2.5 cm x 3.2 cm). Center of paddle to deck, 1½" (3.7 cm). D. Base, 3/8" x 3" x 6" (0.95 cm x 7.5 cm x 15 cm). Front of D to center of B or contacts is 1¾" (4.4 cm). Anti-skid hole in D, same as above.

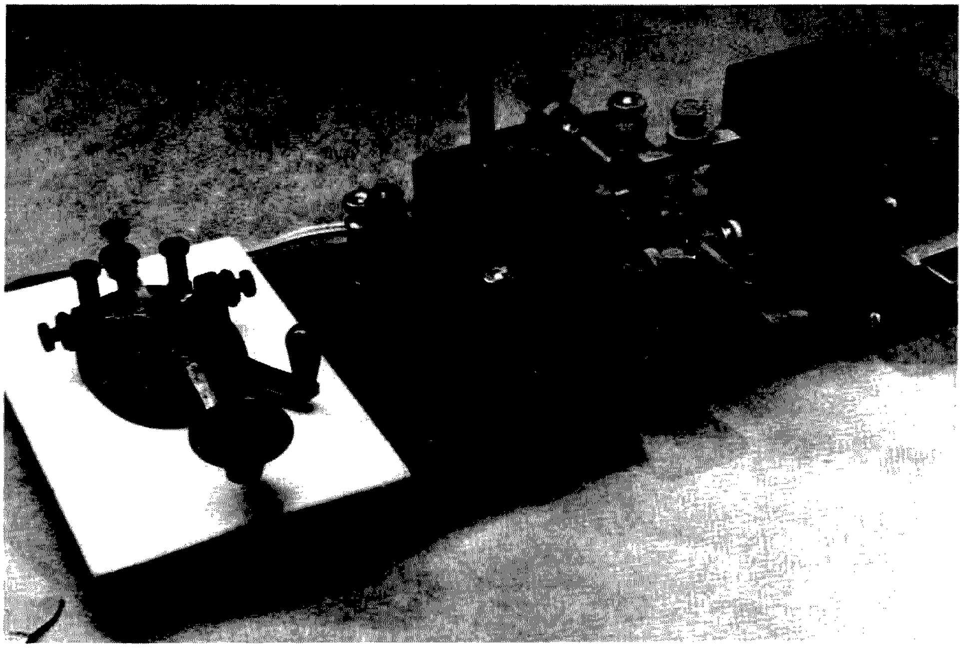
Now to get back to QSD. Recently I read an article by J. K. Bach entitled "Glass Arm."[2] I would like to confirm his interesting, factual observations regarding this affliction. Many newcomers are so devastated when they realize their spacing is terrible that they go out and purchase a microphone. This usually happens after their friends ask, "QLF?" (This is the unofficial, impolite way of saying "QSD," or "are you sending with your left foot?") The result of going on phone at this point is that when some rude person comes on code with SOS, our phone man answers, "This frequency is in use, you lid!" He cannot read his own call any longer. CW is smoke signals to him.

When glass arm set in about two days after I got a ticket to operate, I had to find a reasonable cure. I had a Ford coil going, and no way to get on phone. Some of my peers had built sideswipers (sometimes called cootie keys). They were sailing along at 20 wpm. They had found that running ten Amps through a telegraph key, or most bugs, would cause the contacts to weld closed. So many small silver coins became 20 Amp contacts. Bugs and big fast relays were hard to come by, too. So build a cootie. You never have to worry about glass arm again once you get used to a Great Lakes Sideswiper. But glass arm does last. After reading Bach's article, I loosened the bearings on the straight key and tried his remedy. I could go about 15 wpm fairly well. Above this, QSD. Some good operators can do about 30 wpm on a pump. Not I, alas.

The reason for going into the "fist" aspect of telegraphy is that, as Bach points out, you have to have the right amount of "feedback" (no pun intended). Loosening the bearings on a straight key seems to increase this.

Let's look at the meaning of feedback for a moment. "Once you get the feel of it" is an expression one often hears when trying to get used

to some new experience. Your own built-in servo system has to become accustomed to take the necessary cues from your vision, or hearing, or other senses. The pilot of a boat or plane will readily admit that the autopilot can surpass his ability in the long run. The experienced race driver is in a life or death situation during competition, hanging on the end of a thread which can snap. The ones with the good circulatory ducts and range finding vision live longest. Feedback controls your speech and handwriting and temper and keying – in fact, everything you do while awake or asleep. An interesting experiment in balance is to close your eyes and try to stand steadily on one foot for a moment or two. Sooner or later, if one does not peek, one starts searching for that lost horizon by hopping – to remain upright. Norbert Weiner demonstrated feedback with an automated toy which could move about on the stage avoiding obstacles put in its path. Real magic. Now we have the "sleeping torpedo" lying on the ocean floor waiting for its victims above. We hope it retains its faculties!



The three keys on the left in the illustration are self-explanatory. But that black box on the right is another version of the cootie. It was built to key screen voltage and is shockproof. It may be used as a pump in the position shown. To the left of the home brew bug is my 1921 air-cooled Sideswiper with the 20 Amp contacts. It has been around the world twice with me and still will key a large spark set if you can find one. With it, when a ship rolls to port it will not send a dash of its own as a bug will. This type key is the traditional favorite in rough seas or mobile on rough roads. The tag "Great Lakes" comes from operators there trying to send with one foot on the bulkhead in a storm. You can usually tell who is using one by the spacing it induces in one's fist. The dots are usually longer than the spaces in between them, and the dashes may be a little uneven. This depends on that "fist."

To send with precision is to learn to turn up the feedback, turn on the code practice oscillator, and listen carefully. If you get used to it, make a tape recording of what you think passes for OK stuff. Now play this back. Horrors, you say? So what's the big technique for improvement?

1. Ungrit your teeth and take a warm bath. Then with the thumb and the next two fingers, lightly grasp the paddle in the space position. Breathe normally. Start at 15 wpm with a few Vs.
2. Start every letter by moving the paddle to the left side.
3. In between letters for the spaces, let go of your light grasp without removing your hand.
4. To send every letter or number, go from left to right to left until the letter or number is completed.

Letter A would be left, – RIGHT.
B: L – r – l – r.
C: L – r – L – r.
D: L – r – l, and so on.
Figure number one: l – R – L – R – L.

Take a few runs at the alphabet and some numbers while recording yourself and try the playback again. Better now?

Stick to the procedure. Very important is #3, the loosening of the grasp between letters. This gives you dash length spaces. Try not to rush through the dot sequences (such as in the letters S and H). When you begin to make errors, *stop*. Weiner's machine got psycho and ran into walls when it was tired out. He had to put it to bed and turn off the lights!

When signals are weak and covered with pulses of QRN or M, any sloppy sending is very difficult to copy. Good spacing will permit much better copy by your victim. This of course goes for all keying and for any speed. This also goes for handwriting or skywriting.

The Sideswiper is no toy. It has been manufactured in the past by Bunnell & Co. of sounder and relay fame. Lately a Scandinavian outlet has been advertising one. You may wish to build your own. The outline drawing gives the dimensions. You can use pieces of Mechano, pieces of hacksaw blades, and angle brackets, plus your imagination.

The fixed contacts may be made adjustable for gap width. A gap on each side of about 50 thousandths of an inch with plus or minus 30 thousandths adjustment (1.0 mm ± 0.5 mm) is best. A wide space is recommended for best inter-dot spacing time. If, after practice, you find the spaces are still too short, a relay adjusted to give a few milliseconds delay may be placed between the key and the transmitter. This remedy is a move of desperation and only complicates things. Practice some more.

The Sideswiper will never replace the bug types as a speed key, but it is a cut above a straight key. You will hear it in use by both amateur and commercial stations throughout the world. With care, a speed of 30 words per minute is feasible. You probably will have a fist that your friends will recognize. If you send poorly, and you have a KX prefix, some guy will turn his beam toward YU land and give you a call. It happens with other keyers, too, however. Whatever key you use, try for good spacing or your NAG will be MUD. ■

FCC

Before the
FEDERAL COMMUNICATIONS COMMISSION
Washington, D.C. 20554

In the matter of

Deregulation of Part 97 of the Commission's Rules to simplify the licensing and operation of complex systems of Amateur Radio stations and modification of repeater subbands.

Docket No. 21033

RM-2664
RM-2780

NOTICE OF INQUIRY AND NOTICE OF PROPOSED RULE MAKING

Adopted: December 22, 1976
Released: January 6, 1977

By the Commission: Commissioner Quello absent.

1. The Commission has before it the two above-captioned Petitions for Rule Making, submitted in accordance with the Administration Procedure Act, 5 U.S.C. 553(e), and the Commission's Rules, 47 C.F.R. §1.401. Each of these Petitions for Rule Making seeks revision of Part 97 of the Commission's Rules, 47 C.F.R. §97.1, *et seq.*, concerning the licensing or operation of stations in the Amateur Radio Service.

2. The petitioners in RM-2664, Mr. Gordon Schlesinger and Mr. William F. Kelsey, request explicit recognition in the Rules of so-called "remotely controlled base stations." They state that considerable confusion exists concerning the definition and operation of remotely controlled base stations, and that there is a need for specific rules to regulate the operation of such stations. Petitioners have proposed specific rules which, if adopted, would both add to the rules several provisions concerning remotely controlled base stations and substantially relax the requirements for the operation of such stations. We have also received several comments from interested parties supporting the basic proposals of RM-2664.

3. The Middle Atlantic FM and Repeater Council (T-MARC), petitioner in RM-2780, seeks simplification of the Amateur Radio Service logging requirements, particularly the rules requiring the notation of all third party traffic sent and received, the retention of station logs for one year, and the recording of transmissions from "open access" automatically controlled repeater stations. T-MARC states that much of the logging required by the Rules is of little benefit to either Amateur operators or the Commission and requests that logging requirements be relaxed accordingly.

4. We believe some of the proposals in the petitions we have received merit serious discussion, and we are herein proposing revisions of Part 97 of the Rules which, if adopted, would result in a substantial simplification of the licensing and operation of stations in the Amateur Radio Service presently licensed as repeater stations, control stations, auxiliary link stations, and all other remotely controlled stations, such as remotely controlled base stations. The revisions we are considering, which are discussed at greater length below, would both accommodate many of petitioners' wishes and would be a significant step in the Commission's program of deregulation of the Amateur Radio Service.

5. Since adopting rules governing the operation and licensing of repeater and associated stations in 1972 in Docket 18803, 37 FCC 2d 225 (1972), the Commission has steadily reduced the burden placed on applicants for and licensees of complex systems of amateur radio stations and has afforded such licensees increasingly greater flexibility in the operation of such stations. For example, in Orders adopted January 10, 1974, and November 17, 1975, we deleted the requirements that certain technical showings be submitted with license applications for repeater and remotely controlled stations. In Reports and Orders in Dockets 20073, 20112, and 20113, adopted May 28, 1976, June 11, 1975, and October 29, 1976, respectively, the Commission revised its Rules to permit the linking, automatic control, and cross-band operation of amateur repeater stations.

6. Our experience since adoption of the rules regulating the licensing and operation of repeater and associated stations in Docket 18803 has demonstrated that amateur radio operators are fully capable of developing and operating complex systems of stations with a minimum of regulation by the Commission. We are aware of no compelling reason why amateurs wishing to operate repeater, auxiliary, control, or remotely controlled stations should continue to be required to obtain Commission permission before beginning such operation, as they have in the past. For this reason, we propose to delete those provisions of Sections 97.40, 97.41, and 97.43 of the Rules requiring that licensees obtain prior approval of the Commission to operate a remotely controlled station and requiring that repeater stations, control stations, and auxiliary link stations be separately licensed. We would discontinue the issuance of station licenses with "combined" station privileges: all amateur station licenses would convey authority to operate as repeater, control, auxiliary link, and remotely controlled stations now operate. Functions now conducted by repeater stations would be conducted under a form of station operation known as "repeater operation." Functions now conducted by control stations and auxiliary link stations would be combined in a single form of station operation known as "auxiliary operation." Auxiliary operation would serve to meet the need for point to point links within a system of stations, including the transmission of control and communication signals to other stations within a system, and the need for the automatic relaying of signals received at one location in a system of stations to stations at other locations within the system. Section 97.3 of the Rules would be revised to include new definitions of repeater and auxiliary operation.

7. Similarly, we believe that operators of other remotely controlled stations, such as remotely controlled base stations, have demonstrated the capability of adequately controlling the emissions of such stations, and that the prohibition against the operation of such stations from control points in portable or mobile operation, presently contained in Section 97.110(b) of the Rules, may be unduly restrictive. Accordingly, we propose to revise the Rules to permit the portable and mobile operation of all primary, secondary, and club stations when such stations are in repeater or auxiliary operation.

8. Because no new station licenses would be issued to repeater stations, as such, we propose to discontinue our policy of assigning call signs prefixed with the letters "WR". Stations presently assigned such call signs would be permitted to retain them indefinitely. A licensee wishing to engage in repeater operation and wishing to obtain a "WR" call sign would be required to request that prefix. Stations with "WR" call signs would be restricted to repeater operation, however.

9. Because stations in repeater or auxiliary operation would be taking advantage of specialized modes of operation, we believe the transmissions of such stations should be distinctively identified. We propose to require that auxiliary or repeater operations conducted by stations with "traditional" call signs (that is, call signs not prefixed with the letters "WR") be identified by the addition of a distinctive suffix to the station call sign. Stations in repeater operation would be identified by the addition of the suffix "R", "RPT", or the word "repeater" to the regular call sign. Stations in auxiliary operation would be identified by the addition of the suffix "A", "AUX", or the word "auxiliary" to the regular call sign. We also propose to revise the station identification requirement for stations in repeater operation or stations in auxiliary operation automatically relaying the signals of other stations in a system to require identification of intervals of at least ten, rather than five, minutes.

10. Petitioner in RM-2780 seeks relaxation of certain logging requirements, and we are considering deletion of the requirement found in Section 97.111(g)(2) of the Rules that communications from open access stations in repeater operation under automatic control be either monitored in real time by the duty or control operator or recorded and the recordings retained for a period of thirty days. This requirement, which was originally intended to ensure that licensees have the capability of determining whether their stations were being used properly during periods when no control operator was on duty, has proven to be of little benefit to the Commission and may unduly burden licensees operating "open" repeater stations under automatic control. Of course, the licensee of a station would continue to be responsible for its proper operation, and we wish to receive comments addressing the issue of the continued usefulness to the Amateur Service of the recording requirement in ensuring the proper operation of "open" automatically controlled repeater stations.

11. We are proposing to revise the present rule that all remotely controlled stations have entered in their logs a list of all authorized control points and copies of all control and auxiliary link station licenses to require the entering of the names, addresses, and primary call signs of all authorized control operators. Such a revision would be based on the proposition that the responsibility for the proper operation of a remotely controlled station should be traceable to specific control operators rather than specific land locations. We also propose to require the posting of a list of authorized control operators at the remotely controlled transmitter site. We are not proposing to delete the requirements that the logs of stations in repeater or auxiliary operation contain certain specialized technical information, however.

12. Additionally, it appears that many Amateur operators seek greater flexibility in the choice of frequencies for repeater and auxiliary operation. Operators of remotely controlled base stations, for example, are not restricted to the repeater frequency subbands listed in Section 97.61 of the Rules, although remotely controlled base stations closely resemble repeater stations, and it may be that such stations should be treated identically. We are therefore proposing to permit both repeater and auxiliary operation on all frequencies allocated to the Amateur Radio Service, except 435 to 438 MHz, and to delete the requirement that frequencies below 225 MHz used for auxiliary operation be monitored by the control operator before and during periods of operation. We would revise Section 97.63 of the Rules, however, to emphasize the two principles which have made possible the efficient operation of many amateur radio stations in relatively small spectrum space, namely, that a station using a frequency has first priority in such use over other stations, and that all frequencies allocated to the Amateur Service are shared on a non-exclusive basis. It is presently the responsibility of amateur licensees to strike an appropriate balance between these principles to ensure the fair and efficient use of available spectrum.

13. The Commission is aware that adoption of the rules proposed herein could result in a significant increase in the number of repeater, remotely controlled station, and associated activities pursued by amateur licensees. We are also aware that severe frequency congestion is presently being experienced in some parts of the country, and that the possibility exists that increased interference might result from adoption of these revisions. Many amateurs have voluntarily established techniques for managing available spectrum, and we commend such efforts. We are not prepared to make specific recommendations in this area at the present time, but we are nonetheless interested in receiving comments concerning present and future anticipated interference patterns, whether present techniques used by amateur operators to limit interference are adequate or could be improved, and whether present levels of voluntary cooperation are sufficient to justify continuation of the existing cooperative system. In this regard, we wish to receive comments concerning the utility of the limitations on the effective radiated power of stations in repeater operation contained in Section 97.67 of the Rules. Should such limitations be eliminated in their entirety, modified, or retained without change? What limitations, if any, should be placed on the effective radiated power of stations in repeater operation operating on frequencies not currently listed in Section 97.67 of the Rules?

14. The specific rule revisions we are proposing are set forth in the attached Appendix. Authority for these proposals is contained in Sections 4(i) and 303 of the Communications Act of 1934, as amended. We invite interested parties to submit comments concerning our proposals on or before April 1, 1977 and reply comments on or before April 15, 1977. An original and five copies of all comments submitted shall be furnished the Commission, pursuant to Section 1.419 of the Rules. Respondents wishing each Commissioner to have a personal copy of the comments may submit an additional six copies. Members of the public wishing to express interest in our proposals may participate informally by submitting one copy of their comments, without regard to form, provided the correct Docket number is specified in the heading of the comments.

15. Individuals wishing to inspect the comments and reply comments filed in this proceeding may do so during regular business hours, 8:00 A.M. to 4:30 P.M., in the Commission's Public Reference Room, 1919 "M" Street, N.W., Washington, D.C. 20554.

FEDERAL COMMUNICATIONS COMMISSION
Vincent J. Mullins
Secretary

APPENDIX

Part 97 of Chapter 1 of Title 47 of the Code of Federal Regulations is proposed to be amended, as follows:

1. In §97.3, paragraphs (l), (m) and (n) are revised, as follows:

§97.3 *Definitions.*

(l) *Additional station.* An amateur radio station, other than a primary station, including the following:

Secondary station. An amateur radio station licensed for a land location other than the primary station location. A station assigned a call sign prefixed with the letters "WR" is also considered to be a secondary station.

Special event station. An amateur radio station licensed for a specific land location for operation designed to bring public notice to the Amateur Radio Service and related to the celebration of an event, past or present, which is unique and of general interest to either the public at large or amateur radio operators.

(m) *Amateur radio operation.* Amateur radio communication conducted by amateur radio operators from amateur radio stations, including the following:

Mobile operation. Radiocommunication

conducted while in motion or during halts at unspecified locations.
Repeater operation. Radiocommunication, other than auxiliary operation, for retransmitting automatically the radio signals of other amateur radio stations.
Auxiliary operation. Radiocommunication for remotely controlling other amateur radio stations, for automatically relaying the radio signals of other amateur radio stations in a system of stations, or for intercommunicating with other amateur radio stations in a system of stations.
(n) *Control.* Techniques used to operate an amateur radio station. Must be one or more of the following:
Automatic control. The use of devices and procedures for control so that a control operator does not have to be present at the control point at all times. (Only rules for automatic control of repeater operation have been adopted. Automatic control of all other types of amateur radio operation must be approved by the Commission in advance on a case by case basis.)
2. In §97.40, paragraphs (d) and (e) are deleted, and paragraph (c) is revised as follows:
§97.40 *Station license required.*
(c) An amateur radio operator may be issued one or more additional station licenses. A secondary station license shall not be issued to an amateur radio operator for a land location where a primary station license has been issued to the same amateur radio operator. This section does not apply to stations assigned call signs prefixed by the letters "WR".
3. In §97.41, paragraph (c) is deleted, paragraphs (d), (e), (f), and (g) are redesignated paragraphs (c), (d), (e), and (f), respectively, and paragraph (b) is revised, as follows:
§97.41 *Application for station license.*
(b) Except for applications for club stations and military recreation stations, each application must state whether the proposed station is a primary or additional station. If the proposed station is an additional station, the application must state the type of additional station.
4. §97.43 is revised, as follows:
§97.43 *Location of station.*
Every amateur radio station must have one land location, the address of which appears on the station license, and at least one control point.
5. In §97.53, paragraph (j) is redesignated paragraph (k), and a new paragraph (j) is added, as follows:
§97.53 *Policies and procedures applicable to assignment of call signs.*
(j) A station only engaging in repeater operation may be assigned a call sign prefixed by the letters "WR".
6. In §97.61, paragraphs (a) and (c) are revised and a new paragraph (d) is added, as follows:
§97.61 *Authorized frequencies and emissions.*
(a) The following frequency bands and associated emissions are available to amateur radio stations for amateur radio operation, other than repeater and auxiliary operation, subject to the limitations listed in paragraph (b) of this section and §97.65:
(c) All frequency bands and the associated emissions authorized by paragraph (a) of this section, except 435 to 438 MHz, are available for repeater operation, including input (receiving) and output (transmitting).
(d) All amateur frequency bands, except 435 to 438 MHz, are available for auxiliary operation.
7. In §97.63, the headnote is revised and the text amended, as follows:
§97.63 *Selection and use of frequencies.*
(a) Although an amateur station occupying a frequency listed in §97.61 has first priority in the use of that frequency over other amateur stations, such frequencies shall not be assigned for the exclusive use of any amateur licensee or licensees and must be shared.
(b) All Amateur Radio Service licensees shall cooperate in the selection and use of authorized frequencies and shall take such other steps as may be necessary to minimize interference to other amateur radio stations. Licensees making prolonged use of a particular frequency or frequencies shall cooperate with other licensees in the use of such frequency or frequencies.
(c) Sideband frequencies resulting from keying or modulating a carrier wave shall be confined within the authorized amateur band.
(d) The frequencies available for use by control operators of amateur stations are dependent on the operator license classification of the control operator and are listed in §97.7.
8. In §97.67, paragraph (c) is revised, as follows:
§97.67 *Maximum authorized power.*
(c) Within the limitations of paragraphs (a) and (b) of this section, the effective radiated power of an amateur radio station in repeater operation shall not exceed that specified for the antenna height above average terrain in the following table:
9. §97.83 is redesignated §97.82 as follows:
§97.82 *Availability of operator license.*
10. §97.85 is redesignated §97.82, as follows:
§97.83 *Availability of station license.*
11. §97.87 is redesignated §97.84, and paragraphs (c), (d), and (e) are revised, as follows:
§97.84 *Station identification.*
(c) Amateur radio stations in repeater operation or stations in auxiliary operation used to relay automatically the signals of other stations in a system, shall be identified by radiotelephony or radiotelegraphy at intervals not to exceed ten minutes.
(d) When an amateur radio station is in repeater or auxiliary operation, the following additional information shall be transmitted:
(1) When identifying by radiotelephony, a station in repeater operation shall transmit the word "repeater" at the end of the station call sign. When identifying by radio telegraphy, a station in repeater operation shall transmit the fraction bar $\overline{DN}$ followed by the letters "R" or "RPT" at the end of the station call sign. (The requirements of paragraph (d)(1) of this section do not apply to stations having all call signs prefixed by the letters "WR".)
(2) When identifying by radiotelephony, a station in auxiliary operation shall transmit the word "auxiliary" at the end of the station call sign. When identifying by radiotelegraphy, a station in auxiliary operation shall transmit the fraction bar $\overline{DN}$ followed by the letters "A" or "AUX" at the end of the station call sign.
(e) A station in auxiliary operation may be identified by the call sign of its associated station.
12. A new §97.85 is added, as follows:
§97.85 *Repeater operation.*
(a) Emissions from a station in repeater operation shall be discontinued within five seconds after cessation of radiocommunications by the user station. Provisions to limit automatically the access to a station in repeater operation may be incorporated but are not mandatory.
(b) Except for automatic control operations, as provided in paragraph (e) of this section, the transmitting and receiving frequencies used by a station in repeater operation shall be continuously monitored by the control operator immediately before and during periods of operation.
(c) A station in repeater operation may concurrently receive and retransmit amateur radio signals on one or more frequency bands authorized for repeater operation. A station in repeater operation, operating in conjunction with one or more stations in auxiliary operation relaying radio signals received at other locations to stations in repeater operation, may use input frequencies not available for repeater operation, provided the input frequencies to the stations in auxiliary operation are in frequency bands authorized for repeater operation.
(d) A station in repeater operation shall be operated in a manner ensuring that the station is not used for one-way communications, except as provided in §97.91.
(e) A station in repeater operation, either locally controlled or remotely controlled, may also be operated by automatic control when devices have been installed and procedures have been implemented to ensure compliance with the rules when the duty control operator is not present at the control point of the station. Upon notification by the Commission of improper operation of a station under automatic control, such operation shall be immediately discontinued until all deficiencies have been corrected.
(f) A station assigned a call sign prefixed by the letters "WR" shall engage only in repeater operation.
13. A new §97.86 is added, as follows:
§97.86 *Auxiliary operation.*
A station in auxiliary operation, either locally controlled or remotely controlled, may also be operated by automatic control when it is operated as a part of a system of stations in repeater operation operated under automatic control.
14. §97.88 is retitled and revised, as follows:
§97.88 *Operation of stations by remote control.*
An amateur radio station may be remotely controlled when there is compliance with the following:
(a) A photocopy of the remotely controlled station license and a list of authorized control operators, their names, addresses, and primary call signs, must be posted in a conspicuous place at the remotely controlled operator, or shall be carried in the possession of any control operator controlling the remotely controlled station from a station in auxiliary operation being operated portable or mobile. The transmitting antenna, transmission line, or mast, as appropriate, associated with the remotely controlled transmitter must bear a durable tag marked with the station call sign, the names of the station licensee and all authorized control operators and such other information as may be necessary to enable the Commission to quickly contact the control operators.
(c) Except for operation under automatic control, a control operator designated by the licensee must be on duty when the station is being remotely controlled. Immediately before and during the periods the remotely controlled station is in operation, the frequencies used for emission by the remotely controlled station must be monitored by the control operator. The control operator shall terminate all transmissions upon any deviation from the rules.
(e) A station in repeater operation shall be operated by radio remote control only when the control link uses frequencies other than the station's receiving frequencies.
15. §97.89 (Amended).
In §97.89, paragraphs (c) and (d) are deleted.
16. In §97.103, paragraph (c)(5) is deleted, and paragraphs (c), (d), and (e) are revised, as follows:
§97.103 *Station log requirements.*
(c) The log of a remotely controlled station shall have entered the names, addresses, and primary call signs of all authorized control operators and a functional block diagram of a technical explanation sufficient describe the operation of the control link. Additionally, the following information shall be entered:
(1) A description of the measures taken for protection against access to the remotely controlled station by unauthorized persons;
(2) A description of the measures taken for protection against unauthorized station operation, either through activation of the control link, or otherwise;
(3) A description of the provisions for shutting down the station in case of control link malfunction; and
(4) A description of the means for monitoring the transmitting frequencies.
(d) When a station has one or more associated stations, that is, stations in repeater or auxiliary operation, a system network diagram shall be entered in the station log.
(e) The log of a station in repeater operation shall have the following information entered for each frequency band in use:
(1) The location of the station transmitting antenna, marked upon a topographic map having a scale of 1:250,000 and contour intervals;
(2) The antenna transmitting height above average terrain;
(3) The effective radiated power in the horizontal plane for the main lobe of the antenna pattern, calculated for maximum transmitter output power;
(4) The transmitter output power;
(5) The loss in the transmission line between the transmitter and the antenna, expressed in decibels;
(6) The relative gain in the horizontal plane of the transmitting antenna; and
(7) The horizontal and vertical radiation patterns of the transmitting antenna, with reference to true north (for horizontal pattern only), expressed as relative field strength (voltage) or in decibels, drawn upon polar coordinate graph paper, and the method used in determining these patterns.
(f) The log of a station in auxiliary operation shall have the following information entered:
(1) A system network diagram for each system with which the station is associated;
(2) The station transmitting band(s);
(3) The transmitter power input; and
(4) If operated by remote control, the information required by paragraph (c) of this section.
(g) Notwithstanding the provisions of §97.105, the log entries required by paragraphs (c), (d), (e), and (f) of this section shall be retained in the station log as long as the information contained in those entries is accurate.
17. §97.109 (Deleted).
§97.109 is deleted.
18. §97.110 (Deleted).
§97.110 is deleted.
19. §97.111 (Deleted).
§97.111 is deleted.
20. §97.126 is revised, as follows:
§97.126 *Retransmitting radio signals.*
No amateur radio station, except a station in repeater or auxiliary operation or a radio remotely controlled station, may automatically retransmit the radio signals of other amateur radio stations. A remotely controlled station, other than a remotely controlled station in repeater or auxiliary operation, shall retransmit only the radio signals of stations in auxiliary operation shown on the station's system network diagram.
21. §97.181 is revised, as follows:
§97.181 *Availability of RACES station license and operator licenses.*
(b) In addition to the operator license availability requirements of §97.82, a photocopy of the control operator's amateur radio operator license shall be posted at a conspicuous place at the control point of the RACES station.

FEDERAL COMMUNICATIONS COMMISSION
Washington, D.C. 20554

In the Matter of

Editorial amendments of Parts 0, 1, and 97 of the Commission's Rules to change the name of the Amateur and Citizens Division to the Personal Radio Division.

ORDER

Adopted: January 5, 1977;
Released: January 6, 1977

1. This Order is being issued to change the organization statement of the Safety and Special Radio Services Bureau. The Amateur and Citizens Division has recently undergone reorganization, and the name of the Division is herewith changed to the Personal Radio Division.
2. This amendment relates to internal Commission organization, and hence, the

prior notice, procedure, and effective date provisions of the Administrative Procedures Act (5 USC 553) are not applicable. Authority for the promulgation of this amendment is contained in Sections 4(i), 5(b), 5(d), and 303 of the Communications Act of 1934, as amended and Section 0.231(d) of the Commission's Rules.

3. Accordingly, IT IS ORDERED, effective January 20, 1977, that Parts 0, 1, and 97 of the Rules and Regulations are amended as set forth in the Appendix attached hereto.

FEDERAL COMMUNICATIONS COMMISION
Richard D. Lichtwardt
Executive Director

NOTE: Rules changes herein will be covered by T.S.I(74)-7.

APPENDIX

Parts 0, 1, and 97 of Chapter 1 of Title 47 of the Code of Federal Regulations are amended, as follows:

In Sections 0.132(e), 1.951(a), 97.25(d), and 97.41(d), the words "Amateur and Citizens Division" are deleted, and the words "Personal Radio Division" are substituted in each instance therefore.

Before the
FEDERAL COMMUNICATIONS COMMISSION
Washington, D.C. 20654

In the matter of

Revision of Parts 0, 1, and 97 of the Commission's Rules to institute a system of Interim Amateur Permits in the Amateur Radio Service

ORDER

Adopted: January 5, 1977
Released: January 13, 1977

By the Commission: Commissioner Lee absent.

1. Under the existing Amateur Radio Service licensing system, Amateur Radio Service licensees successfully completing examinations for higher class licenses than the licenses they hold must wait while their new license applications are processed at the Commission's Gettysburg, Pennsylvania, facility before they may take advantage of the added privileges afforded them by their new operator licenses. A delay of several weeks may be involved, although both the licensee and the Commission are aware of the results of the examination and know a new license will be issued.

2. By this Order, we are revising Parts 0, 1, and 97 of the Commission's Rules to permit the issuance of Interim Amateur Permits by the Engineers in Charge of the various Commission field offices. Interim Amateur Permits (FCC Form 660-B) will be issued to applicants already holding amateur operator licenses as soon as possible after successful completion of higher class license examinations and will authorize immediate utilization of all additional operating privileges acquired. Licensees operating under the authority of Interim Amateur Permits will be required to add distinctive suffixes to their station call signs denoting the Commission district office at which their higher class licenses were obtained. Interim Amateur Permits will be valid for a period of 90 days or until issuance of the permanent station and operator licenses, whichever is less. A record of the issuance of an Interim Amateur Permit will be retained at the office of issuance, and requests for confirmation of an operator's status must be directed to that office.

3. Authority for these amendments appears in Sections 4(i), 5(d), 303, 307, 308, and 309 of the Communications Act of 1934, as amended. Some of the amendments adopted herein are editorial and procedural in nature, and the prior notice and public procedure provisions of the Administrative Procedure Act, 5 U.S.C. 553, are not applicable. Further, because of the enormous number of Amateur and Citizens Radio Service license applications we receive each month, rapid implementation of the interim permit system is essential, and we are, for good cause, dispensing with the prior notice and public procedure provisions of the Administrative Procedure Act as impracticable.

4. Accordingly, in view of the foregoing, the public interest being served thereby, IT IS ORDERED that Parts 0, 1, and 97 of the Commission's Rules ARE AMENDED as set forth in the attached Appendix effective March 1, 1977.

FEDERAL COMMUNICATIONS COMMISSION
Vincent J. Mullins
Secretary

NOTE: Rules changes herein will be covered by T.S.I(74)-7.

APPENDIX

Parts 0, 1, and 97 of Chapter 1 of Title 47 of the Code of Federal Regulations are amended, as follows:

1. In §0.314, a new paragraph, (v), is added, as follows:

§0.314 *Additional authority delegated.*

(v) To issue Interim Amateur Permits to Amateur Radio Service licensees, pursuant to Part 97 of this Chapter.

2. In §1.922, a new FCC Form and Title are added, as follows:

§1.922 *Forms to be used.*

FCC Form	*Title*
660-B	Interim Amateur Permit

3. In §1.925, the headnote is amended, and a new paragraph, (e), is added, as follows:

§1.925 *Application for special temporary authorization, temporary permit, or interim amateur permit.*

(e) Upon successful completion of a Commission supervised Amateur Radio Service operator examination, an applicant already licensed in the Amateur Radio Service may operate his amateur radio station pending issuance of his permanent amateur station and operator licenses by the Commission for a period of 90 days or until issuance of the permanent operator and station licenses, whichever comes first, under the authority of a properly executed Interim Amateur Permit (FCC Form 660-B). An Interim Amateur Permit conveys all operating privileges of the licensee's new license, but may be set aside by the Commission within the 90 day term if it appears that the permanent operator and station licenses cannot be granted routinely.

4. §1.934 is revised, as follows:

§1.934 *Procedure with respect to amateur radio operator license.*

After an application for an amateur radio operator license is accepted and an examination conducted by the Commission in accordance with Part 97 of this Chapter, the examination is graded by the office supervising the examination. If the applicant is successful, and if the applicant already holds a license in the Amateur Radio Service, the supervising office issues the applicant an Interim Amateur Permit conveying all operating privileges of the applicant's new operator license. The results of the examination are forwarded to the Commission's Gettysburg, Pennsylvania facility for issuance of a license.

5. In §1.1115, paragraph (c)(6) is revised, as follows:

§1.1115 *Schedule of fees for the Safety and Special Radio Services.*

(c)

(6) Applications for Interim Amateur Permits or Novice Class licenses in the Amateur Radio Service, applications for amateur stations under military auspices, and applications in the Radio Amateur Civil Emergency Service (RACES).

6. In Section 97.3(d), the definition for "operator license" is amended and a new definition, "Interim Amateur Permit," is added, as follows:

§97.3 *Definitions.*

(d)

Operator license. The instrument of authorization including the class of operator privileges.

Interim Amateur Permit. A temporary operator and station authorization issued to licensees successfully completing Commission supervised examinations for higher class operator licenses.

Station license. The instrument of authorization for a radio station in the Amateur Radio Service.

7. A new §97.32 is added, as follows:

§97.32 *Interim Amateur Permits.*

(a) Upon successful completion of a Commission supervised Amateur Radio Service operator examination, an applicant already licensed in the Amateur Radio Service may operate his amateur radio station pending issuance of his permanent amateur operator and station licenses under the terms and conditions of an Interim Amateur Permit, evidenced by a properly executed FCC Form 660-B.

(b) An Interim Amateur Permit conveys all operating privileges of the applicant's new operator license classification.

(c) The transmissions of amateur radio stations operated under the authority of Interim Amateur Permits shall be identified in the manner specified in §97.87.

(d) The original Interim Amateur Permit of an amateur radio operator shall be kept in the personal possession of or posted in a conspicuous place ih the room occupied by such operator when operating an amateur radio station under the authority of an Interim Amateur Permit.

(e) Interim Amateur Permits are valid for a period of 90 days from the date of issuance or until issuance of the permanent station and operator licenses, whichever comes first, but may be set aside by the Commission within the 90 day term if it appears that the permanent operator and station licenses cannot be granted routinely.

(f) Interim Amateur Permits shall not be renewed.

8. In Section 97.87, paragraph (f) as amended, is redesignated paragraph (g) and a new paragraph (f) is added, as follows:

§97.87 *Station identification.*

(f) When operating under the authority of an Interim Amateur Permit with privileges authorized by the Permit, but which exceed the privileges of the licensee's permanent operator license, the station must be identified in the following manner:

(1) On radiotelephony, by the transmission of the station call sign, followed by the word "interim," followed by the special identifier shown on the interim permit;

(2) On radiotelegraphy, by the transmission of the station call sign, followed by the fraction bar $\overline{DN}$, followed by the special identifier shown on the interim permit.

(g) The identification required by this section shall be given on each frequency being utilized for transmission and shall be transmitted either by telegraphy using the international Morse code, or by telephony, using the English language. If the identification required by this section is made by an automatic device used only for identification by telegraphy, the code speed shall not exceed 20 words per minute. The Commission encourages the use of a nationally or internationally recognized standard phonetic alphabet as an aid for correct telephone identification.

The Capacitor Comparator

-- super simple test equipment

If your junk box is like mine, tucked way back in the corner is a spot where you throw all those unmarked, unidentified capacitors that you just KNOW will come in handy some day. Round ones, square ones, flat ones, fat ones, piston and bypass ones, and those a guy could have a great time screw-drivering if he just knew where to use 'em.

The simple circuit here is an easy one-evening project that when completed will provide an audio tone comparison of a built-in reference capacitor to an unknown capacitor connected to the test clips. Bearing in mind that the larger the capacitor the lower the tone, it is a simple matter to establish the value of unmarked units. The circuit, as described, will identify caps between .5 pF and .001 uF by providing tones between 8 kHz and 100 Hz. The heart of the tester is a 555 timing IC and may be operated from any dc voltage source between 8 and 14 volts.

An LED indicator is provided for testing values larger than .001 uF which do not produce a tone but merely turn the LED off and on. A .1 uF unit will trigger the indicator at approximately 5 Hz.

Piston, compression, and rotary trimmers may be identified by first making a comparison fully closed and then fully opened. Small gimmick caps made from twisted leads are also easily sized.

The LED is, of course, optional, as well as the number of reference capacitors. Any NPN switching or audio transistor may be used in place of the MPS6512. If the LED is not needed, the transistor may be eliminated and the speaker with its 1 uF coupling capacitor is connected directly to pin 3 of the IC. Why not try a Poly Paks unmarked assortment — 100 caps $1.98?? Happy sorting. ■

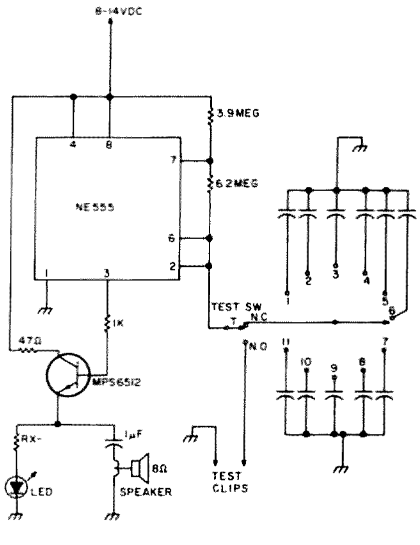

Fig. 1. LED indicator and RX — see LED specs. Capacitor bank: 1 = .7 pF; 2 = 3 pF; 3 = 5 pF; 4 = 10 pF; 5 = 25 pF; 6 = 50 pF; 7 = 100 pF; 8 = 330 pF; 9 = 470 pF; 10 = 680 pF; 11 = 820 pF. Test switch — SPDT push-button.

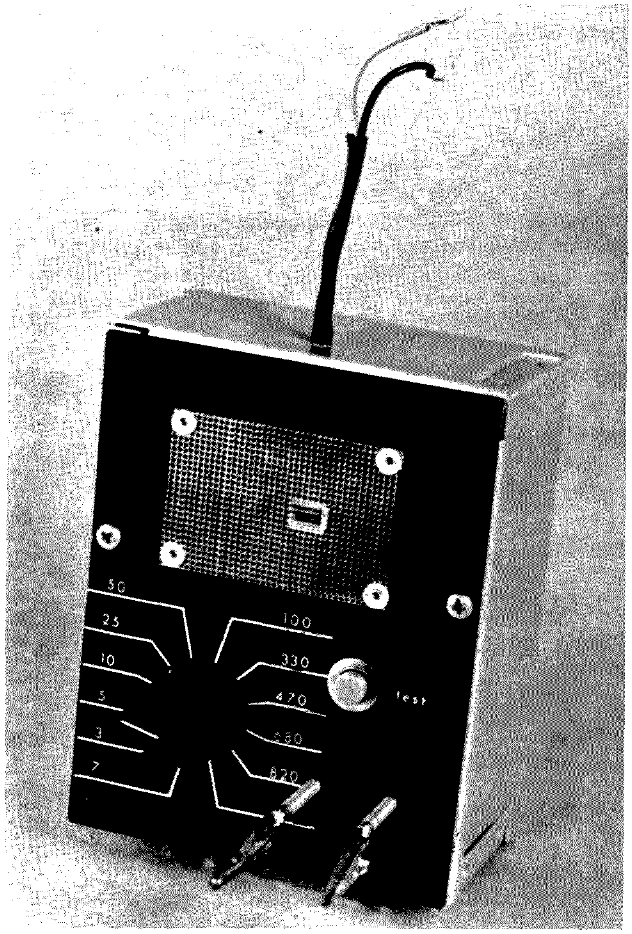


The LED indicator is located behind the jewel on the speaker grill. The test clips are mounted on small bronze springs for easy attachment to various caps.

Logical Storage for Logic

-- not recommended for CMOS

My first method of storing integrated circuits left me with the vague feeling that perhaps I hadn't arrived at a perfect solution to my problem.

D. E. Stanfield
3408 Catalina Dr.
Atlanta GA 30341

To be honest, I really don't care if you paid less for your chips than I did for mine. Nor am I interested in the psychological motivations that caused you to buy them. What really counts is that we both know that integrated circuits in a jumbled pile do not facilitate rapid retrieval of specific chips.

By way of illustration, assume that today's mail brought several plastic bags of assorted chips. Their price in the magazine had been so low that you rushed off a check and now you have them in your hands. If you are like most of us, you will take your bags and find a place to examine their contents.

Those who have hunted for buried treasure or used metal detectors know the special emotions you will feel as you sort through your chips. A 7400. Nice but ordinary. A 7425. What is it? A 74196. Maybe it's not gold but it sells for more than this whole bag cost. And so on. You recognize many numbers and remember several projects involving their use.

Eventually, you've seen them all and, hopefully, are pretty pleased with your assortment. At this point, what do you do? You can do what I used to do and dump them into boxes for storage. You can throw them out or immediately build a super, self-clocking digital do-it-all.

If you choose the first option, let me point some things out. First, you probably won't remember every type of chip in those boxes for more than two minutes. Second, even if you do remember a specific chip being in a certain box, odds are that it won't be among the first twenty-seven you check. Finally, the pins on integrated circuits do not possess amazing mechanical strength. Once in a pile, these pins have the irritating habit of so interlocking themselves with the pins of neighboring

chips that severe bending leading to breakage can result from trying to separate them.

One solution to all of these problems would be to mount integrated circuit sockets on perf or circuit board and plug in all your chips. However, a couple of moments spent checking the prices of such sockets will probably convince you that there must be a better way. If they don't, please send me all the money you can spare as I need it more than you.

When I faced this problem, I sought a solution that would allow me to plug in my chips, but I didn't want to spend a lot of time or money. I evolved two simple solutions that quite adequately met these requirements. My first method was to punch small holes in a piece of cardboard and insert the chips into those holes. The primary advantages of this technique are extremely low cost, readily available materials, and the fact that the stacking of several boards results in a compact, high-density storage system. The principal disadvantage is that it does take a little time to punch the holes.

My other answer to these problems was to stick the chips into a sheet of styrofoam and go enjoy some liquid refreshment. This method takes less time but I had a lot trouble finding the styrofoam I wanted and the sheets run about a dollar each.

Either method works very well and, for various reasons, I use them both. However, I tend to use the cardboard for chips I don't need right away and the styrofoam for those I've targeted toward specific projects. Using both methods is a logical choice for me, but you can certainly use either one by itself.

There are two other points that may assist you in selecting which method to use: It is possible to use both sides of the styrofoam (which cuts costs in half), and the punched holes in the cardboard act like sockets (which allows you to reinsert other chips into a vacated position). This is handy if you are trying to arrange the chips by type.

If you decide to use cardboard, your first step should be to gather your materials together. These include corrugated cardboard, graph paper ruled ten spaces to the inch, a suitable punch, a knife, a ruler, some masking tape, and a pen or pencil. The cardboard should be larger than the overall dimensions you desire so that it can be trimmed to size. I cut mine eight by ten inches but you can adjust these figures to fit your requirements.

I found the graph paper ruled off at ten spaces to the inch at an office supply firm. While I had to buy an entire pad, this particular size of graph paper lends itself perfectly to laying out boards using integrated circuits.

The punch can be anything from a small nail fitted with a handle to a sharpened test probe. I used a little gadget called a Seam Ripper, used in sewing to open buttonholes and pick threads.

Once you've gathered these materials, you can begin fabrication of the board by using the knife to trim the cardboard to the size you want. I used eight by ten inches, but another size may suit your purposes better. A metal ruler or yardstick makes cutting a straight line very easy. If you anticipate needing more than one board, now is the ideal time to cut them.

After the cardboard is cut, you may lay it aside and prepare a sheet of graph paper which will be used as a guide when punching the holes. My paper measured eight and one-half by eleven inches, so my first step was to draw off a block the size of my boards (eight by ten inches). If your board will be larger than your graph paper, you can glue or tape several pieces together to form a larger sheet. Again, draw off a

Use a metal ruler or yardstick and a knife to cut a piece of cardboard to the desired size.

A sheet of graph paper ruled off with ten spaces to the inch is prepared as a guide to be used when punching holes in the cardboard.

After the graph paper is properly ruled, it is cut to the same size as the cardboard and attached to it with masking tape. Then, each of the seven intersections on the segments of the horizontal lines measuring six spaces in length are punched. The tool shown in use is called a Seam Ripper, normally used in sewing.

block on your paper corresponding to the size of your board.

The next objective is to draw off a grid marking where the chips will be placed. The most common chips have fourteen pins arranged seven on a side. The pins are spaced 1/10 of an inch apart and the spacing between the two sides is 3/10 of an inch. As the chips protrude a bit beyond the pins, each chip will require a minimum space measuring 3/10 by 7/10 of an inch.

Some of the more complex integrated circuits having more than fourteen pins use a spacing of one-half inch between rows of pins. If you are using these types, you will need to make allowance for this fact and develop your own layout.

Whether you wish to devise your own spacing arrangement for ordinary fourteen pin chips or the larger variety, let me suggest that you leave a good bit of room around each chip. This will make inserting and removing chips much easier since your fingers will have enough space to get a good grip on the chip.

If you wish to duplicate my spacing, begin by ruling off a rectangle measuring eight by ten inches. Then, arrange your graph paper so that one of the eight inch sides is at the top. Place a mark in the upper left-hand corner at a point six spaces from the top and seven spaces from the left of the eight by ten inch rectangle. Similarly, in the upper right-hand corner, place a mark six spaces from the top and seven spaces from the right side of the rectangle.

In the lower left and right corners, place marks at points seven spaces from the bottom and seven spaces from the sides. Join the four marks to form a smaller rectangle within the eight by ten inch borders.

Then, starting at the top of this new rectangle, count down three spaces and draw a horizontal line from edge to edge of the smaller rectange. Next, count down four spaces from the previous line and draw another horizontal line. Continue by alternating the spacing between horizontal lines three and four spaces until you reach the bottom line of the small rectangle.

When you finish the horizontal lines, begin in the upper left corner and count six spaces to the right. Draw a vertical line from top to bottom of the inside rectangle. Then count four spaces to the right of the previous line and draw another vertical line. Continue by alternating six and four spaces until you reach the right side of the inside rectangle.

At this point, cut the graph paper along the lines of the eight by ten inch rectangle. Use masking tape and fasten this eight by ten inch graph paper to the top of the eight by ten inch cardboard previously prepared. Be sure to align the edges of the graph paper and cardboard correctly.

After all the holes have been punched, the graph paper is removed from the cardboard and the chips are inserted.

With the graph paper side up, lay this cardboard on a piece of wood and begin punching. Punch a hole at each intersection along the horizontal lines that are six spaces in length. Punching both ends and all points between them will give you seven holes in a row. This corresponds with one side of a chip.

As you are punching, penetrate the graph paper and the cardboard until you feel your punch against the wood. It is not necessary to go through the bottom layer of the cardboard, just be sure that you touch it.

After you have punched all the six space segments on each horizontal line, you should remove the graph paper from the cardboard. This graph paper can be used as a punching guide for many other pieces of cardboard, so don't throw it away.

All that is left is to insert your chips. Remember to check for bent pins and to push each chip into place firmly.

For those of you who feel that the previous method would take up more of your time than you can spare, let me strongly recommend that you give the following system of chip storage a try. The reason styrofoam lends itself so well to holding chips is that you can easily push the pins into the styrofoam without having to drill or punch holes to hold them.

While there are two ways (neat and not so neat) to use the styrofoam, both require at least one sheet of styrofoam. I thought that this would be easy to find, but some quick looking around proved me wrong. Not only did I look in all the wrong places, I finally ran out of wrong places to look. My search eventually led me to one of those craft shops where they sell string and weeds.

After I had finally located my styrofoam, someone mentioned that friendly florists are a great source. I haven't checked this out yet. I feel that it is my duty to warn you that as you search you can expect a lot of busy clerks to direct your path to their supply of styrofoam ice chests.

Once you have your styrofoam, you must decide how neat you want your finished stock of chips to look. If you really don't care, simply start pushing one chip at a time into any area of the styrofoam that looks inviting. When you run out of room or chips, you can stop.

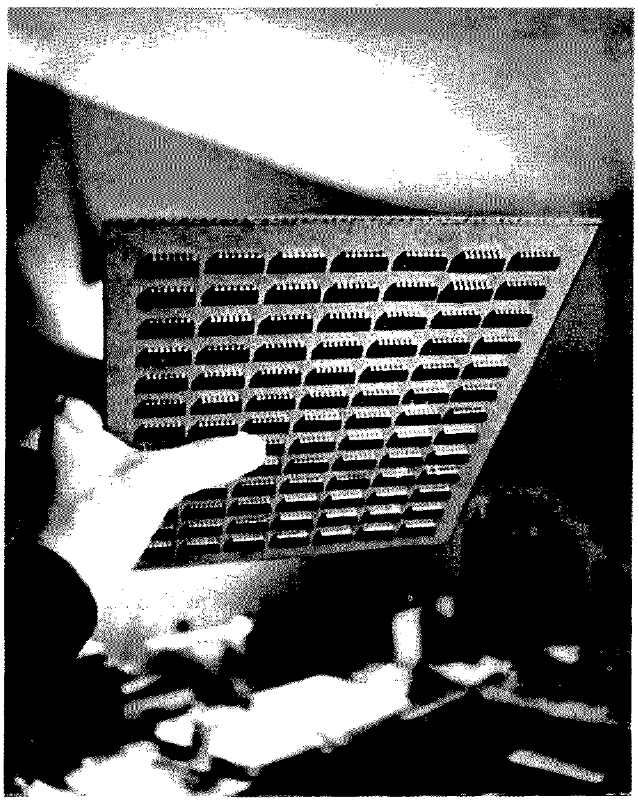
If you would prefer to have the results of your efforts look more professional, allow me to suggest a simple way to do so. In essence, you will make a ruler with appropriate marks to show the proper location of each chip. This ruler should be about 3/8 of an inch thick so that when placed on edge, this thickness will serve as an easy to use guide for setting the spacing between rows of chips.

To make this ruler, choose a length of wood (such as molding) roughly 1/2 by 3/8 inches high and wide. One of these dimensions should equal the spacing you want between rows of chips. The length of this wood should be an inch or two greater than the width of your styrofoam sheet.

Next, lay this piece of wood across the width of your styrofoam so that the side whose thickness you want as the distance between horizontal rows of chips is on the bottom. In other words, imagine that there are already two rows of chips correctly spaced on the board and place the wooden strip so that it would exactly fit into the space between the rows.

Using a pen, draw a mark on the wood at each edge of the styrofoam. Try to equalize the lengths of the wood extending beyond each edge of the styrofoam before making the marks.

Now you will have to determine the spacing



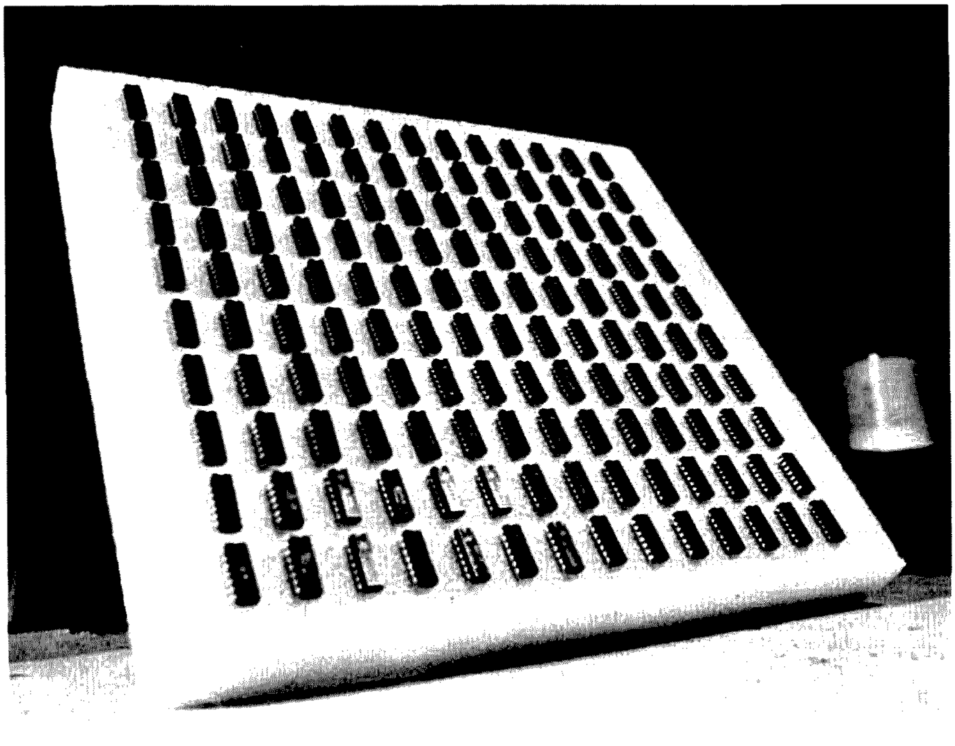
This fully populated board is being held upside down to show that the cardboard will hold the chips quite securely.

This photo demonstrates how the homemade ruler serves as a spacing guide to set the distance between horizontal rows of chips.

Marks on the homemade ruler show where to place each chip. Marks near each end of the ruler serve to align the ruler with the edges of the styrofoam.

between the individual chips on the horizontal rows. An easy way to figure out the spacing is to set out a row of chips on a sheet of graph paper and working with the width of your board setting the outside limits of the row, line up the chips at different spacings until you have them like you want.

Once you are satisfied with the spacing, bring your ruler next to this row of chips and mark the locations of the edges of each chip on the ruler. Do not forget that the two marks you previously placed on the strip of wood located the edges of the styrofoam. Therefore these two marks should be lined up so that they are spaced equal distances beyond their respective chips.



Once all the chips have been inserted, you will have a neat and very practical storage system.

To use this ruler, set it across the styrofoam so that the marks for the edges line up with the edges of the styrofoam. Place it near the top edge of the styrofoam so that all chip and edge locating marks are visible to you and the correct side is on the bottom. Adjust its location until the edge nearest you corresponds to the place where you want the top edge of your first row of chips. Then, while holding the ruler firmly in place with one hand, use the other to plug in the chips.

An easy way to do this is to line up the ends of the chip with the chip location marks and then align the pins so they are flush with the edge of the ruler. Once these conditions are met, push the chip straight into the styrofoam. When seated correctly, the pins on the side of the ruler will be touching it.

Once you complete the first row, shift the ruler down and reposition it so that its top edge is touching the bottom edge of first row of chips. Again, line up the edge locating marks with the edges of the styrofoam and insert chips at the marked locations.

Follow this procedure with all succeeding rows and you will finish with a neat set of stored chips. While things may sound a bit involved, you will find that once you get started, things proceed quite rapidly.

For those of you who like systems thinking, it is not difficult to keep a record of the location of every chip. Assign each board a number, each horizontal row a letter, and each position on the horizontal rows another number. Then an entry such as 07-F-05/7410 would tell you fifth chip on the sixth row of the seventh board was a 7410. ■

CB Can Do Some Things Better

-- are you missing some fun?

David F. Norman
622 W. Sunset Blvd.
Fort Walton Beach FL 32548

Much has been written about "stepping up" to amateur radio from CB. As amateur ranks begin to swell with newcomers from Citizens Band, we can expect to see many more articles on the subject. However, transition between services should not be – and isn't – a one way process. A great many amateurs have realized that CB does things that no phase of amateur radio – including 2 meters – can do. Let's take a look at some of the reasons why the "compleat ham shack" should include a CB transceiver.

Travel Aid

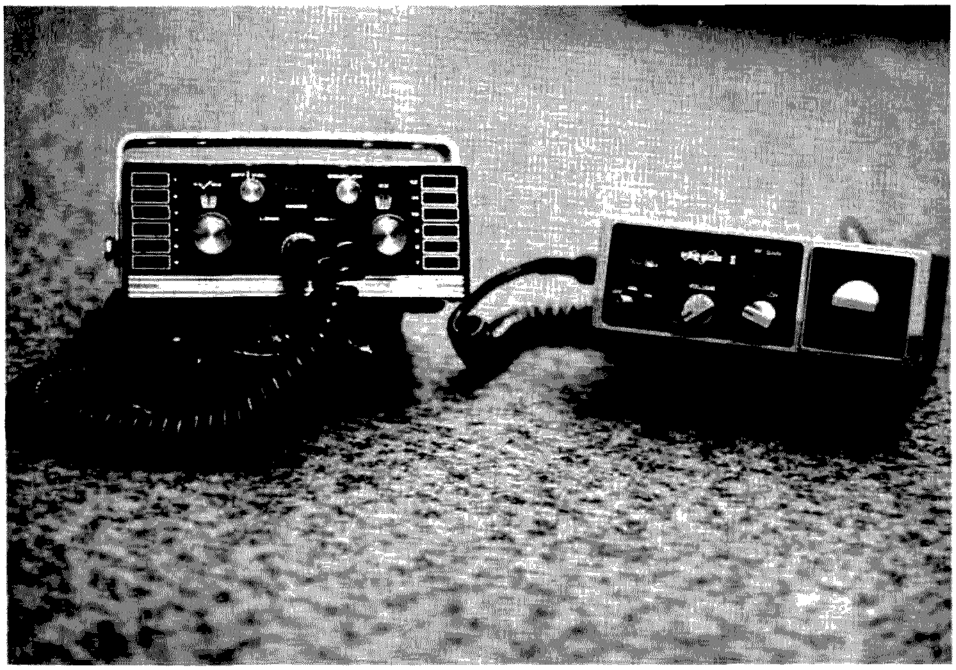
Use of CB by amateurs is seldom limited to the shack. Nowadays, you can see quite a few mobile operators with both 2 and 11 meter antennas and rigs installed in the family car. And why not?

Amateurs on the highway have the same problems to cope with as other motorists. Perhaps in your area you can always hit the nearest repeater; you would find many other locations in sparsely populated areas where you could not reasonably expect to reach anyone, anywhere, with a 2 meter mobile. Even if you are equipped with high frequency gear, your contacts are more likely to be entertaining than helpful as far as your circumstances on the highway are concerned.

Let's assume that you *are* well within range of a local repeater. What is the chance of receiving timely information regarding road conditions and traffic jams on 2 meters? Pretty slim, right?

Okay. At present there is no better system than CB for finding out what is happening a few miles ahead. There is no more reliable way – on the average – of requesting help when faced with car trouble or the discovery of a serious accident. Despite the short range and interference of CB, it has proven its worth time and time again to the traveling public.

Perhaps you don't care for his operating procedure, but if you have a bad back and your wife is faced with changing a tire on the camper in one hundred degree



More and more amateurs are finding CB a useful addition to their mobiles and shacks – with good reason.

weather, are you going to refuse help from the "Trottin' Turkey?" Not unless you are a damn fool.

If the XYL has never been quite able to grasp the necessary theory and code — or didn't care to — you may have wished that there were some legal way for you to keep in touch when she is out in the car. This is the beauty of CB. All that is necessary to operate a CB unit is a simple application. Under one license, your entire family is covered. But you knew that already.

One of the large CB manufacturers used to run ads to the effect that no woman should drive alone without one. An awful lot of CBers agree.

Of course, no amateur would be guilty of speeding, so under most conditions "Smokey reports" would not be of value to him. However, no one likes to be surprised when he is a long way from home.

One thing more about traveling with a CB: You don't have to worry about CBers holding against you the fact that you hold an amateur ticket. Most of them are pretty tolerant.

Introduction to Radio

It is not at all uncommon for someone to be exposed to amateur radio and then vow to get his own ticket. Unfortunately, a great many aspiring amateurs get discouraged by how much code and theory they have to learn before they can do any phone work. Perhaps even your XYL would get on the ball, if she only knew how much fun radioing really is.

A little taste of honey often makes someone want more. With the encouragement that you can give and the fun and experience that CB can offer, your XYL (or YM or YL) has a good chance of making the grade. Even if you have been licensed for several years, there is a good chance that your XYL has never talked to *you* over a radio. With CB, you can put her on the air in a couple of hours.

Overcoming Mike Fright

You might not believe it, but every CBer that you hear on the air had a first time — just like you. The same trembling, proud, sweaty feeling that grabbed at you grabbed him. At one time the 10-signals that he now uses so glibly and the CB slang that assaults your ears were as awkward to him as Q-signals and amateur pleasantries were to you. I know that this statement will probably prompt a lot of argument, but the fact is that most

Fig. 1. Tom Goldsmith WB4EQU is only one of the active amateurs who have added CB. Tom's highly modified 2 meter rig with its T/T pad still has the place of honor on the hump, but the CB comes in handy, too.

Fig. 2. One of the major pluses in CB's favor is the "family style" license. This means that wives — such as the author's XYL — may have the advantages of two-way communication, even if they are not electronically inclined.

QRL	10-6
QRG	10-93
QRT	10-3
QSL*	10-4
QSM	10-9
QRV	10-8
QSP	10-5
QSY	10-27
QTR	10-36
QTH	10-20
QRS	10-11
QRRR	10-33

*Roger is usually phone acknowledgement.

Fig. 3. Partial comparison of CB "10-signals" and amateur "Q-signals." Not all of these translate exactly.

CBers are people just like amateurs: They simply like to talk on the radio.

Whether you agree with that or not, you will have to admit that the enthusiasm of CBers is contagious. If you nourish that enthusiasm, and spring for a CB unit – perhaps trade that old receiver for one – for the family car, there is a good chance that within a few weeks there will be more than one amateur in your family.

The CB in the Shack

If you decide to install a CB in the car, you will probably want to install a matching unit at home. Not only would you then be able to call home when you are on the way home from work, but you would also have the peace of mind that comes from knowing that your wife or daughter can call you for help – without having to leave the car.

Even if you are reluctant to install the CB in your domain, the shack, you can find a corner in the kitchen or family room where it can repose in all of its humble glory. Ask the XYL. She is bound to have an opinion.

Public Service

So far we have talked about all of the wonderful things that CB do for you. However, this is another of those two-way streets. Along with the rights and privileges which come with that CB license come certain responsibilities – moral, if not legal.

It goes without saying – almost – that you will operate the CB unit in as legal a manner as you operate that ham rig, but there is more to it than that. When you receive a road report, you obligate yourself to the sender of it. Since you will likely not have a chance to return that favor to him personally, this obligation makes you bound to do the same for others somewhere down the road.

Your obligation to CBers probably already exists, *even if you don't have a CB unit.*

Remember that last disaster that struck your area? It might have been a hurricane, a brush fire, an earthquake, or a tornado. Whatever it was, you can bet your favorite QSL card that there were CBers right in there donating their time and equipment, and even risking their lives, to do their part.

During Hurricane Eloise, I was busy on the CB base in the Civil Defense Center, talking to and encouraging brave, scared CBers who stayed out until the last minute to warn sleeping residents in low-lying areas that the hurricane was going to strike Fort Walton Beach and not pass west as the weather wizards had predicted. Most of these men had families that they would have much rather been with. Few of them were even regular members of the CD. The major qualification that most of them had was the CB unit in the car or truck.

I don't mean to imply that hams weren't there; the job that they did on 2 meters was great. And then the lights went out all over town.

Emergency repeater power is fine. However, when the water is up to your headlights and the wind is blowing at 125 mph, it is damn hard to get to most repeater sites.

Another instance comes to mind.

During the same storm, emergency shelters were opened in the schools. Anticipating power and phone failure, we sent a mobile unit to each school to provide communications back to CD control (we stopped using callsigns early in the storm and used only unit numbers; there was simply too much traffic to handle). After the storm had abated, but before the people were released from the shelters, one of the shelter CB operators wanted to secure. We (I) told him to hang tight for another hour. It is a good thing that I did.

Within a few minutes, he called in asking for an ambulance. A young girl was hemorrhaging badly. All at once, another station broke in. The breaker was another of the CBers. This one was parked beside the ambulance at one of the hospitals – his own idea – and as he reported that the ambulance was on the way, I could hear the siren wailing.

Would anyone like to try to compute the odds of having two units equipped with 2 meter rigs in both of those places at that particular time?

Any amateur who claims to be interested in community service should definitely equip himself with CB. In several emergencies, stretching over the last decade, I have personally seen CB used as both the common denominator providing interface between various radio services and as the main bulwark of communications

Fig. 4. Terry Bishop, owner of this wrecker, is typical of community-minded CBers who volunteer their time and equipment during emergencies and disasters.

when everything else quit.

Then, too, there is simply the matter of numbers. If your small child turned up missing, you could get every amateur in the area to look. If you happen to live in a fair-sized city, the only problem with asking for help on the CB channels would be that you might have more help than you'd know what to do with. Every single car would be CB-equipped and able to maintain contact with all of the other units.

Get With It

If all of the above isn't enough reason for you to trot out and get one of the 23-channel units or a more sophisticated 40-channel model, look at it this way.

Any CBer could tell you that the skip conditions on 10/11 meters are pretty bad – pretty good, depending on how you look at it. If you are wondering whether 10 is hot or not, all that you have to do is turn on the CB and listen for the "Golden Boy" to come booming out of Nova Scotia. Then turn off the CB and fire up the 10 meter rig for a good crack at a little DX.

Or you can always tell yourself that the CB unit hidden in the bottom of your shopping bag and smuggled into the house will be converted to 10 – just as soon as you check it out with a "good buddy" or two. The same goes for that Moonraker beam. All that you have to do is shorten the elements a bit. Of course, you had first better put it together like the manufacturer says.

Whatever words you might have to eat, or rationalization you feel compelled to make, don't let misguided pride stand between you and one of the handiest pieces of gear that you have ever seen. Just think what your knowledge of radio and antennas can accomplish with something that works well for the rankest tyro. ■

LETTERS

from page 17

Band radio service." The following frequencies were offered: 27.54 to 28 MHz and 222 to 224 MHz.

You should be aware that the amateur service use of the 220-225 band is increasing explosively, plus the proposed "Communicator" license with its reduced licensing requirements for citizens will necessitate full use of this band by the amateur service.

We at this time question your committee's judgment in the matter. From the Table of Frequency Allocations, FCC Vol. 2 Rules and Regulations, we look at the following frequencies being held or possibly "hoarded" for total government use: 225-235 MHz, 235-267 MHz, 335.4-399.9 MHz, and 406-420. These are all fixed and mobile frequencies and exclude Space Telemetry and Aeronautical Radionavigation.

Please submit to us the following information:

Names of each agency with its representative and his position with the agency, methods used to determine spectrum availability, and were the following tools used: 1. % of occupancy level based on monitoring to determine actual usage; 2. Accurate user records and forecasting; 3. Careful evaluation of the priorities of the needs of the United States citizens.

Please notify me within 10 days if it will be necessary to invoke the Freedom of Information Act to expedite this request for information.

The results next month. — Ed.

KENTUCKY — EAT CROW!

"Big Brother" is here and now in the shape of Uncle Charley, and only Uncle Charley has the constitutional authority to regulate the transmission of energy on the airwaves (in the USA).

And not even the FCC yet has the power to tell us what we can *hear.* We are not yet to the degree of regulation held by the Russian government over their citizens.

I believe that if any of those poor Kentuckians who have lost equipment and money in fines were to fight back, they could make the State of Kentucky eat crow. It is highly unlikely that the anti-scanner law is constitutional, and it most likely violates the Federal Statutes that set up the FCC in the first place.

If you will recall, some states attempted to outlaw radar detectors (receivers) but were unable to enforce the laws, and you never hear of anyone having any problems on that score any more.

I would think you could suggest in one of your columns that those poor Kentuckians should get in touch with the American Civil Liberties League, their lawyers, their congressmen, etc., and have the stupid law repealed.

DOWNHILL

I am a computer repairman for the U.S. Army Hawk missile system. I read your magazine for the computer content. However, you have opened the world of ham radio to me.

Being a CBer 11 years, and watching it go downhill, well, I no longer have a CB. Several months ago I purchased a Hallicrafters S-120. This and your magazine made me decide to try.

I borrowed some Ø5 Charlie (radio operator) tapes from a friend. I am also interested in learning more about how the radio works.

Anyhow, I want to thank you for putting out such a good magazine. It has helped me quite a bit. Keep up the good work.

Michael P. Olbrisch
APO New York

SKIPLAND

I was into CB before I got into amateur radio, and still do both. With all the Novices and Techs now working the Novice bands, I am surprised at the lack of activity on 10 meters. The problem must be no one knows when the band is open. For the hams with CB rigs, better yet SSB CB rigs, if there is any opening at all, you will hear it on channel 16 lower sideband. When I hear skipland on 11 meters, I go to 10 meters and usually make a contact or two. Hope this stirs up a little more activity on 10 meters.

Leon R. Harris WD8BYM
Battle Creek MI

And the Novices shall lead them. — Ed.

TIMES CHANGE

I think I will let *73* go for a year or so. I first subscribed due to an interest aroused by a pile of back issues from the late 60's — the magazine had a different spirit then. There were a lot of articles for beginners, written in a way that encouraged the less knowledgeable hams to become involved in good stuff like construction. Building — sometimes that's *all* there was. While *QST* was laying out all the mathematical formulas for calculation of the celebration of the angle of the disinclined pandemonium, *73* was telling us about the projects we could have on the air by Wednesday night (well, Thursday afternoon, anyway).

The magazine that arrived in response to my subscription didn't remind me much of the old *73*. The thing that struck me as most out of place was the obsession* with computers. They obviously have some application in amateur radio technology, but enough's enough.

That you would finally publish a computer magazine was a foregone conclusion — I'm sure it will set the pace for the hobby computer crowd. I'm wondering what will happen to *73* once you get fully occupied with *Kilobaud.* I'll be glancing at someone else's issue from time to time to find out.

K.W. Farlow WA3DBL
Wilmington DE

*That word wasn't used as an epithet. You, of all people, would probably agree that a moderate amount of obsession is better than some other things one could mention.

Built a circuit with a CK722 yet, Farlow? Times change. — Ed.

BACK TO BASICS

I would like to congratulate you on the type of articles which appeared in each issue of *73* during 1976. For the most part they were superb, and I will readily agree that same was far ahead of *QST* for the same period.

Also, you are absolutely correct in guessing that my interest in computers has grown steadily through the past year, but one thing bugs me. In several issues of *73* during 1976, there were articles on learning the machine or basic language needed to program a computer and at least one article describing how to use a Model 15 teleprinter for a readout device, and one page of the "Holiday" issue lists various publications beneficial for use after you have built a computer or acquired one. BUT, to my knowledge, there has not been a SINGLE article on how a beginner or experimenter can build his first basic fundamental computer. Please correct me if I am wrong.

Popular Electronics in their August, 1976, issue gave what appears to be a very good article on building the "Elf" basic computer and promised future articles dealing with readout devices, but to my knowledge none has appeared.

I have on order Texas Instruments' computer manual for beginners and the advertisement says the manual describes how to build a basic "machine."

Would it be violating house rules to tell me if an article on "computer construction" is forthcoming in an early issue of *73?*

I have E & L Instruments' "Digi-Designer" and also their "Breadbox," which I find to be of tremendous help in building up test circuits such as were in "How Do You Use ICs?" and other similar articles in *73* for 1976.

Again, congratulations for a job very well done in 1976, and I am convinced that the 1977 issues will be of the same breed.

John W. Yochum W9URQ
Princeton IN

Authors, take note! — Ed.

THE AVERAGE HAM

Would like to see fewer articles on computers, etc., which are written at the level of graduate engineers, and more articles of interest to the average ham, especially those who are relatively new to amateur radio. I like your propagation forecasts.

R. C. Mader WN4AGT
Englewood FL

Try Kilobaud, *OM. — Ed.*

ACCELERATED FUROR

I just simply had to write and say that I enjoy *73* so much! Being a student confronted with an ever-increasing financial crisis, I have had to systematically eliminate "unneeded?" items with an accelerated furor. *73* gets passed over every time (I'm sorry to say I can't say the same for other magazines). I have enjoyed reading the various letters from readers for quite some time and now feel a need to make a few comments of my own.

I really can't see the reason why some readers look down upon, or only simply tolerate, the various I/O articles in *73.* As I see it, a ham who enjoys his hobby and takes it and himself seriously can't afford not to be even remotely interested in the truly fascinating area of microprocessors. For example, a ham who is active in any two, three, or four of the various aspects of ham radio such as RTTY, DXing, CW, Contests, OSCAR, and EME could save a bundle in $$ as well as space by integrating most of the peripheral equipment needed for these various modes into one unit. Enter the microprocessor! Load a cassette and you have an FSK converter, generator, and display. Another program and your EME antennas are aimed at the moon and follow it across the sky. Run another program and you have a contest keyer/memory and a good log. How about a digital signal processor for those weak DX signals down at the low end?

Sure, you might have to learn something about the uP, but we all had to learn something about electronics before we got our ham tickets, too! The next time you find yourself down at one of the radio shops, make a physical movement with your arm and pick up one of the books on microcomputers (pay for it, though!). I guarantee it will be the first of many devoured before you have been even

partially satiated. All I can say is that a modern ham station utilizing a microprocessor for control of its various operations results in a very powerful system to be sure, one that many a non-ham computer buff would be envious of.

Thanks for a good magazine.

Scott G. Turner WB2DLE
Princeton NJ

I/O HELP

73 is responsible for getting me interested in microprocessors and I have ordered my SC/MP and 8K of memory from a couple of the advertisers in your magazine. But many basic questions are starting to bother me. For instance, I want to make the busing system compatible with the Altair bus system so I can use boards and peripherals made for these systems. Can I make the bus in such a manner and then wire the connections for the SC/MP to work or is the SC/MP busing totally different? I guess what I want to know is more on microprocessor hardware in general. I know some of my questions will be answered by the National manual with the kit, but I still need more. What does a computer do when it receives a command to AND the accumulator or to Exclusive OR the accumulator? This I do *not know* either. Can you recommend any good reference material on these subjects, hardware and machine programming?

One more question, or two really. I have purchased the keyboard kit from Poly Paks, another advertiser in *73*, and have some questions on it also. The keyboard produces negative logic by using 7404 hex inverters; they are also used to produce TTL compatibility. I am wondering if I can use 7407 hex drivers which would then not invert the logic and give me positive output. The ROM used with the keyboard is an AY 5-2376; the control and shift inputs are not wired and I want to know what input is necessary to cause the ROM to produce a shifted and control output. Can you answer the question or can you give me an address to write where I can get an answer or spec sheet?

John W. Daugherty WB8DEG/ON8II
SSG Radio, TX Site
USA ELM SHAPE
APO NY 09055

Can someone give John a hand here? If you've ever been stuck overseas trying to get information on something like hobby computing, I'm sure you can appreciate what he's going through. I answered most of his questions, but I'm sure he would still appreciate some help. — John.

INSTANT REPLAY

I just got my first issue of *73* after a few months vacation from your subscription lists. I notice that there is some debate concerning the I/O section. Some of those letters sound like an instant replay from a few years ago.

I can remember back in 1969 when I put my Motorola 5-V in the car and got on 2 meter FM for the first time. I was in Des Moines, Iowa then — FM may have been big on the coasts by '69, but in the Midwest there were just scattered pockets of activity around the cities. Everything was on 94. You worked through the repeater on 34/94 when you wanted to play with the new toy (it was in some guy's basement, I think — very primitive and experimental), but if you wanted to understand the other station's audio, you switched to 94 simplex. The signals were usually stronger on simplex anyway!

The point is that we were more or less shooting in the dark back then as far as repeaters were concerned, and about the only place to get information and any ideas at all from repeaters in other parts of the country was *73*. I used to get a chuckle every month reading letters from those "old goats" who kept telling you (and us) that there was no future in FM and that you should get back to printing articles on "real" ham radio.

Now it's microprocessors. I have to admit that I was one of the "old goats" myself this time. I was upset with *73* because all of my precious FM and repeater articles were being shoved aside for computers (or so it seemed). Since you weren't into "real" ham radio anymore, I let my subscription drop.

But now we're talking about computer control for our repeater, and those little uP chips have been showing up in ovens, sewing machines, even cars. Some of the local hams who work for the big electronics outfits here assure us that they'll be in just about everything soon. Maybe your present transceiver works without one, but you can bet a uP will be the heart of your next one! Not to mention a dozen other things in the shack that will be controlled by them.

So I'm back, Wayne, and I can sit and chuckle again about the guys who'll be out in the cold when computers revolutionize our hobby. It's going to be soon.

Mark Johns WAØRGV
Minneapolis MN

THE UNINFORMED

I have been reading the letters from others for the last few months and am tired of hearing the same old thing, that is, that *73 Magazine* is all computers and no radio. Just did a bit of research and came up with some interesting figures on the subject which you might want to pass along to the uninformed.

I also took the data for the entire year of 1976 from the master index printed in the Holiday issue and it bears out the fact that *73 Magazine* is still very much a ham magazine and not a magazine for the microprocessor users as many would like us to believe. There were 493 major articles listed in the index for 1976 of which only 48 were "I/O" or 9.736%. In the areas of receivers, transmitters, FM, VHF, antennas and mobile operation, there were 140 major articles or 28.397%. The 140 articles do not include such things as commercial equipment, construction, theory, new products, Novice, power supplies, RTTY, ATV, SSTV, surplus, test equipment, or touchtone pads, which will increase the total to 343 major articles or 69.57% of the total.

It seems to me that when a person is condemning a magazine, they should take the time to get their facts straight, as it only took me about ten minutes to add up all the numbers, which does not seem to be much to ask.

There, I feel better now. Keep up the good work on the magazine and keep the I/O articles coming as every thing new that comes out is always a help in understanding our hobby. The I/O articles help broaden my knowledge of electronics in general and thus broaden my knowledge of ham radio.

By the way, I am in the process of preparing an article for a later issue covering the field of converting the 23 channel CB rig to ten meter operation. With the shift in sunspot activity, ten meters will be the DX band that it was back in 1948-1952 when I was working the world with 5 Watts.

KEEPING UP WITH THE TIMES

Perhaps Doug DeMaw W1FB, *QST* Technical Editor, should read *73 Magazine* to keep up with the times. In the December issue of *QST*, his article titled "Measuring Transmitter Power" says the following: "Perhaps it is time for some manufacturer to develop a directional wattmeter which can be used to read both power characteristics — Average and Peak . . ." For Mr. DeMaw's information, such a meter has both been already developed, and is also advertised in *73 Magazine*. It is the Swan WM 3000, which does exactly what the Technical Editor of *QST* wants. And I might add that keeping up to date means that articles published will be up to date, and this is what readers want in the magazines they pay their hard-earned money for. To me, *73* not only keeps up with the times, but stays ahead of them.

My reason for writing this as a letter to the editor is that I am quite fed up with the poor quality of articles in *QST*, their verbosity, and this is a prime example of their own editors not even knowing what's what.

William Vissers K4KI
Cocoa Beach FL

I've been saying that for years. — Ed.

VEAL CURRY

Would you please have a building article in a forthcoming issue of *73* which is for an LED digital clock which presents time in the 24 hour mode? In addition to being powered by an ac power supply, incorporate a secondary supply (battery) in case of power (ac) loss.

Secondly, how can I get the recipe of the veal curry which Wayne Green spoke of in the Editorial?

L. A. Watts WBØWOD
Colorado Springs CO

Veal curry? Sure. Sautee 4 diced onions; when slightly browned and tender, add 2# veal cut into small cubes (about 1") and sear the veal. Salt . . . pepper . . . 2 tablespoons of curry powder . . . add garlic (about two cloves cut up fine) . . . then add a cup of white wine (doesn't have to be all that good wine); cover and simmer for about 50 minutes. Add more wine if the level gets low . . . you want to have plenty of gravy, you know. Mix 2 heaping tablespoons of flour and a half cup of cold water and add slowly to the curry to make the gravy. Simmer a bit longer, stirring to keep it from sticking. Salt to taste. If you like a "hot" curry, add some red pepper.

You'll want some condiments. Small dishes of these are passed around the table and sprinkled over the curry and rice. Oh yes, the rice . . . make some white rice . . . put the curry over it when you serve . . . then everyone can sprinkle the condiments as they please on top of the curry.

Condiments: crushed pineapple (Hawaiian, if at all possible . . . not Taiwan, Philippines, etc.), chopped peanuts, shredded coconut, toasted coconut shreds or chips, raisins which you've simmered a while to plump, Major Grey's Mango Chutney, chopped hard boiled egg, some people like shredded toasted bumalo fish (known also as Bombay Duck), but I hate the stuff, chopped well-done bacon, chopped dill pickles.

That should feed four well . . . and you won't forget it. — Wayne.

A New Breed of Voltage Regulators

-- throw away your old 309s

Amateurs are probably building more electronic circuits today than ever before. With the multitude of IC circuits that are available these days to do complicated functions, frequently one has little more to do than build up the manufacturer's recommended circuit to complete his project. However, in breadboarding these new circuits, one piece of equipment that is an absolute must for the test bench is a good, well-regulated power supply.

Several manufacturers have offered three-terminal fixed voltage IC regulators for some time. These ICs just about took all of the work out of power supply design, as long as you only wanted one fixed power supply voltage. However, making up a variable supply was a little messy.

Well, designers at Fairchild Semiconductor[1] realized many IC users require voltages other than the ones that they had standardized for their series of fixed voltage regulators. So they recently introduced two new IC circuits that fill in the gaps in their series of fixed voltage regulators. These two circuits are the 78MG positive regulator and the 79MG negative regulator.

This article will introduce basic circuits for using these two ICs at fixed voltage levels, as well as for variable power supplies. As with most IC circuits, it doesn't do to simplify, so we will also show some of the pitfalls to avoid.

[1] Fairchild Semiconductor, 464 Ellis Street, Mountain View CA 90402.

Features

The 78MG and 79MG variable output voltage regulators offer unique features which make the circuits very simple to use, while providing protective features which are hard to obtain in a discrete design.

The most outstanding characteristics of these IC regulators are protection against output short circuits and protection against excessive power dissipation. These features make the regulators difficult if not impossible to destroy through misuse. A third related characteristic limits the ICs' output transistors to safe area operation.

The regulators are designed to supply up to 500 mA of current, with input voltages in the range of +5 to +35 volts for the 78MG, and -2.2 to -30 volts for the 79MG. The maximum input voltage for either is 40 volts.

The devices are packaged in what is called a "mini-batwing four-terminal package." The wings on the package allow the device to be secured to a heat sink to increase power dissipation capabilities. Both devices feature line regulation of 1% when the input voltage is varied from 7 volts to 35 volts, and load regulation of 2% when the load current is varied from 2 mA to 500 mA. The quiescent current is 2.5 mA, and the regulators require a minimum of 2 volts margin between input and output to stay in regulation. The power dissipation is internally limited to 7.5 Watts.

The older three-terminal, 78 series fixed voltage regulators had an internal voltage reference which was sensed through a resistive voltage divider network. The ratio of resistance in the voltage divider network was preset internally when the chip was manufactured. The 78MG and the 79MG regulators use the same concept, except that there is no internal voltage divider network. Instead, this point is brought outside the package by means of a fourth pin. Thus, all you have to do to set the regulator for any

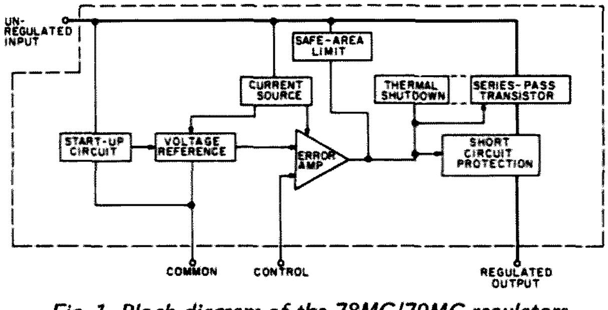

Fig. 1. Block diagram of the 78MG/79MG regulators.

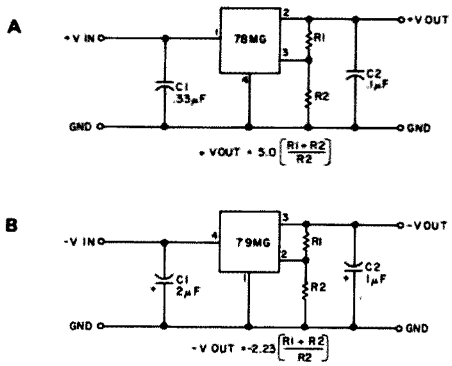

Fig. 2. Basic regulator circuits. (a) Positive regulator; (b) negative regulator.

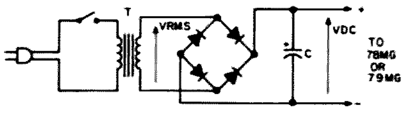

Fig. 3. Unregulated supply.

voltage within its range is supply two resistors of the proper value to supply the feedback voltage to this fourth terminal.

It is the addition of this fourth terminal which meant that the familiar three-terminal, power tab package had to be abandoned in favor of a four-terminal package. The package that was chosen is basically a stretched out four-pin plastic dip package with two "wings" protruding from each side for a heat sink.

The Insides

Fig. 1 shows a block diagram of the 78MG and 79MG regulators. The internal structure, with a few minor refinements, is identical to that of the earlier three-terminal regulators. The major exception is that one input to the error amplifier is brought outside the package so that you can supply any reference voltage you wish.

Let's get a brief idea of internal circuit operation before we get caught up in applications. The start-up circuit contains a zener diode and two transistors which have the purpose of bringing the circuit into initial regulation. After it is in regulation, the start-up circuit is biased off. The error amplifier compares the voltage at the control input to the internal voltage reference and generates an error signal of the proper polarity if the two voltages are not the same. This error signal either increases or decreases the bias current into the series pass transistor, which in turn increases or decreases the regulated output. The safe area limit and thermal shutdown circuits provide protection against normal operating overloads. The short circuit protection reduces the current available to the series pass transistor in the event of an output short circuit.

The regulators also contain a 30 pF MOS capacitor to increase stability and lessen the possibility of oscillation. The regulators achieve thermal stability through careful balancing of positive and negative temperature-coefficient components.

Basic Regulator

Fig. 2 shows the simplest configuration in which the positive and negative regulator can be used. This is really all you need to place in front of an unregulated power source in order to produce a stable well-regulated voltage source. The input capacitor, C1, is necessary to stabilize the regulator under all possible conditions. Although the manufacturer lists this input capacitor as an optional item "needed only if the regulator is located more than a few inches from the unregulated supply filter capacitor," I would very strongly suggest always including it. For the few pennies of extra cost, you may save yourself from destroying a regulator chip. It also allows you a lot more freedom in locating the unregulated source, and in choosing the unregulated supply filter capacitor.

Conversely, C2, the output capacitor, is really not necessary for regulator operation, although it does tend to improve transient response. I would suggest, if you intend to use the regulator to supply power to switching loads, such as TTL circuits, you would be well advised to include an output capacitor of approximately the value shown. One further comment about output capacitance: If there is any chance that you might drive a very large capacitive load (e.g., as large as the unregulated supply filter capacitor), you must provide extra protection for the regulator to prevent possible destruction of the chip. A diode in series with the output, large enough to handle all the output current, will provide quite adequate protection from reverse voltage. In all cases, the application of a reverse voltage between the output and input pins of the 78MG and 79MG regulators must be avoided.

You might notice that the input and output capacitors of the negative regulator are larger values. The larger values are required to maintain the same level of stability as the positive regulator. The formulas for calculating the output voltage are given in the figure. The two constants of +5.0 and -2.23 are the magnitudes of the internal voltage references and represent the lowest obtainable regulated voltage. If a pot is used in place of R1 and R2, an additional fixed resistor should be included in the ground leg of the pot. This linearizes the relationship between the rotor position of the pot and the

Vrms NOMINAL TRANSFORMER SECONDARY VOLTAGE (Vrms)	Vdc AVERAGE DC OUTPUT VOLTAGE (Vdc)	Vout DESIRED REGULATED OUTPUT VOLTAGE (Vdc)	I1 MAX. LOAD CURRENT (Amps)	C1 MIN. CAPACITOR SIZE (Microfarads)
6.3	8.2	2.23* to 5.3	0.5	1200 @ 20 V
		2.23* to 5.3	1.5	3600 @ 20 V
		2.23 to 4.5*	0.5	600 @ 20 V
		2.23 to 4.5*	1.5	1800 @ 20 V
12.6	16.3	2.23* to 12.5	0.5**	600 @ 35 V
		2.23* to 12.5	1.5	2000 @ 35 V
		2.23* to 11	0.5**	300 @ 35 V
		2.23* to 11	1.5	1000 @ 35 V
25.2	32.8	5 to 29.5	0.5**	300 @ 75 V
		5 to 29.5	1.5	1000 @ 75 V
		5 to 26	0.5**	150 @ 75 V
		5 to 26	1.5	500 @ 75 V

*This voltage is obtained only with 79MG.

**If the 78MG/79MG is used without an external pass transistor, full current may not be available for lower output voltages, since the IC will limit power dissipation to 7.5 Watts.

I/O EDITORIAL

Microcomputers are two years old, practically speaking. Though a few experimenters were messing around with the Intel 8008 a little before the Altair 8800 system was announced in January, 1975, there was little available in information or hardware. The Altair, launched with a lot of publicity and advertising, got the whole field going and fired up a new breed of hobbyist.

Now, after two years, perhaps we have enough perspective to get a handle on what we have and where we may be going.

In some ways, there has been a great deal of progress; in others, not much has changed. There are now over twenty different microcomputer systems being made for the hobbyist, and well over 150 different compatible boards for the Altair bus. There are over 50 computer stores around the country helping to sell these systems to hobbyists.

In the "not much change" area is programming. It took about a year for the first computer language to be made available ... BASIC. Some systems still don't even have that much for the user to work with. There are a few games available and a couple books of business and scientific programs, but not a lot else. Magazines such as *Kilobaud* are starting to bring more programs to users, but this aspect of computing has been slow to develop. Higher level languages such as FORTRAN and COBOL are still not generally available for the microcomputers, so the use of these systems is still quite limited.

Many of the early hobbyists started building a computer kit without reading the fine print (so to speak) and they gradually discovered that a CPU does not a computer make. Their $500 CPU looked fine, but it wouldn't do anything until $1000 or so of memory was put in the box. Then they had to hook on a printer or a video terminal, another $250 to $900 out of pocket. Now, with about $2000 invested, and Altair BASIC up and running, they could play hangman or lunar landing games. Star Trek needed another $500 in memory ... sorry about that.

Hobbyists needed some medium to store programs and to record data for the computer to use. The first choice was the cassette recorder, and every manufacturer of microcomputers promptly came out with a different system, making it so no two hobbyists with different systems could swap programs or data. This situation is still up in the air, with no system as yet satisfactory enough for the industry to accept it.

Business had long been using floppy disks, and some eventually were made to work with the hobby systems. They are still rather expensive for the hobbyist, prone to mechanical problems, and not supported with very much in programs to make them do a lot.

The hobby market has not been a large one, so most of the firms involved have been very small. There are a little over 10,000 hobby computer systems up and running so far, according to the best estimates. The readership of the hobby magazines (such as *Kilobaud*) make it plain that there are about 50,000 or so people who would like to get systems, but have been waiting for more information before getting their feet wet. That's a $100 million market, so it's well worthwhile for the small firms to court.

Even bigger, by a couple orders of magnitude, is the coming market for these systems. Hobbyists will be paying the costs of hardware development, which should bring us some relatively inexpensive and dependable computer systems which will be sold by the millions to business. We'll be seeing them in every office, in stores, in schools and in homes, just as we see TV today. It's a market that can't fail to come along when the hardware and software are ready.

We radio amateurs have a tremendous advantage in something like this by virtue of our head start with electronics. Most computer folk are programmers, and they are at a disadvantage because the hardware end of computers is much more difficult to understand than programming. Most hams have already read enough digital articles in the ham magazines to be able to understand the fundamentals of computer systems ... they really aren't all that complicated for us. This is why such a high percentage of the pioneers in hobby computing are hams.

Hams have another major advantage over other computerists ... they have some great things to do with their systems once they get them running. The hobby computerist is stuck with a bunch of games and not a lot more to do that can't be done better with a hand calculator ... and more cheaply. The ham can use the computer to run a repeater, to find Oscar, to operate his RTTY station, to simplify winning contests, keep his log, aim his beam for DXing, copy Morse code ... stuff like that ... combining the fun of doing something practical with knowledge that is of immense value in this exploding field.

One of the major needs today is for information. The manufacturers of computer equipment are way behind on their documentation, so we need to help each other. When we figure out how to interface a BCD keyboard with an ASCII computer, we should write it up. When you write a good ham program for your system, pass it along (via *73*, of course). If you will pass along what you've learned to others, we'll all benefit.

Many of the *73* readers work with microcomputer firms ... or with the manufacturers of peripherals ... please try to overcome the documentation lag by writing articles for *73* on the use of these gadgets. We all want to know. If there are any questions on how to write just send for our poop sheet .. or go ahead and do it without said poop sheet ... as long as you double space your typing.

Okay?

KILOBAUD POSTERS

The reader reaction to the first issue of *Kilobaud* is coming in and it is most gratifying. The most often complimented is the choice of articles ... they are by some of the top people in this new field, so it is no wonder that they are good reading. Expert writers are somehow able to write so beginners can understand.

The type is set pretty much like *73*, so there are a lot of articles in the magazine as compared to the other magazines ... 22 of them in the same space where another magazine gets in 14. More for your money, you might say. A few *73* readers have noticed that articles in *73* are far more compact than those in the other ham magazines.

The hobby computer field seems to have settled down to two main magazines ... *Kilobaud* and *Byte*, with *Byte* aiming at the computer scientist and *Kilobaud* at the beginner. *Microtreck* hasn't been seen since August. *SCCS Interface* and *Interface Age* seem bent on mutual self-destruction, with lawsuits and other time and money wasting jazz. This has left both magazines very scant on material.

The posters? Oh yes ... we've got some posters which we hope will interest more people in reading *Kilobaud* ... and we're hoping you'll dip in an oar to help. We'd sure like to get these posters hung up where they might bring in subscribers ... places like schools with computer science departments. A student is going to be far more valuable to himself and to anyone he works for if he is not only a professional, but also a hobbyist. We've seen that in amateur radio for years.

An employee of a firm making computers, accessories, or even a software firm will be far more valuable if he has the initiative to learn on his own. A subscription to *Kilobaud* could provide this impetus. Thus we'd like to have *Kilobaud* posters in as many firms involved with computing as possible ... the firms will benefit from it ... a lot.

If you have a school or business to spot one of our posters, please drop a note to marketing director Sherry Smythe and we'll get one off to you, complete with a bunch of subscription cards attached.

FREE SUBSCRIPTIONS

Bruce Seals called recently to say that he wants to see what will happen if he offers a free subscription to *73* with every direct sale of an 8K memory board ... either the 500 ns model at $269 (special) or the 250 ns model at $295 (also special). I tried to think of a good reason not to – couldn't. I did suggest that he offer an alternate of our three microcomputer books as an incentive for readers who were life subscribers, and he agreed to that. Either one is a $15 value ... so if you find yourself ordering an 8K memory from Seals you might mention whether you prefer a year of *73* or the three computer books: *Hobby Computers Are Here*, *The New Hobby Computers*, and *Microcomputers Simplified!* Bruce will take it from there.

High Quality Display

- - with complete cursor and video control

Photos by Mike Barnaby

The video display described in this article is a high quality display with large capacity (2048 characters), extremely high speed (normal memory cycles are used to enter or read data from display memory), and unlimited formatting capability. In writing this article, I have assumed the reader has at least a basic working knowledge of digital logic and is familiar with typical uses of a video display.

The display itself consists of 32 lines each containing 64 characters for a total of 2048 characters. The character set includes both upper and lower case characters and the Greek alphabet, in addition to some special characters. Normal display of a character is white on black, but the video may be inverted on a character by character basis to produce a black character in a field of white.

The display memory is accessed directly by the microprocessor as though it were normal memory. This allows information to be written to or read from any location of the display memory at any time. Scrolling the display then becomes a software process, and as such allows the display to be arbitrarily partitioned into several segments, each being scrolled independently of the others. In fact, programs may be loaded directly into display memory and executed.

The display does not, however, steal cycles from the processor (as many who have seen my display immediately ask). Display memory is normally isolated from the processor bus and is used by the display control circuitry in parallel to normal processing. When the processor performs a read or write cycle utilizing a location within the display memory, control of that memory is automatically switched to the processor. This means that the processor steals cycles from the display when needed.

A Basic Video Display

Before I go into a detailed description of my display, I'd like to go through a simplified description of the fundamental process of creating a raster scan display.

A raster scan CRT (Cathode Ray Tube), an example of which is a normal TV set, produces an image by moving an electron beam horizontally across the screen 262½ times (from left to right) while moving it once from top to bottom. On every other vertical trace of the beam, the start of the horizontal tracing is delayed slightly to produce a field of horizontal lines between the lines drawn by the previous trace. Each of the two fields of lines is called a frame. The process of causing the lines of the second frame to fall between the lines of the first frame is called interlacing.

Movement of the electron beam is synchronized by special pulses which are part of a video signal, the horizontal and vertical sync pulses. For instance, suppose that the beam has just completed a trace across the face of the CRT. The horizontal sync pulse will cause the beam to go back to the left side of the tube (retrace) and begin a new sweep. Likewise, a vertical sync pulse causes the beam to move back to the top of the screen. Another part of the video signal is the blanking. Blanking pulses follow each of the horizontal and vertical sync pulses and serve to blank out the retrace of the beam so that it does not show up as unwanted light on the screen. The final part of a video signal is just the video information itself. This information controls the intensity of the electron beam as it is being swept across the CRT. The sync, blanking, and video information are all combined to produce a single signal which controls the CRT monitor.

Producing a display of characters on a raster scan CRT involves only the synchronization of an appropriate train of pulses with the horizontal and vertical information. I have shown a simplified block diagram to accomplish this in Fig. 1.

The clock and timing information block is responsible for generation of the horizontal and vertical sync and blanking pulses. This information is fed directly to a video combiner and is also used to control the operation of several counters. The row counter and the column counter provide an address to the memory (which contains the characters to be displayed). The data from the memory serves as one input to a read only memory called a character generator. The character generator contains a matrix of dots for each character (see Fig. 2). Since only one row of dots for a character may be produced on a given scan of the electron beam, a scan line counter is needed to tell the character generator which particular row of dots is currently being called for. The output of the character generator is loaded into a shift register and

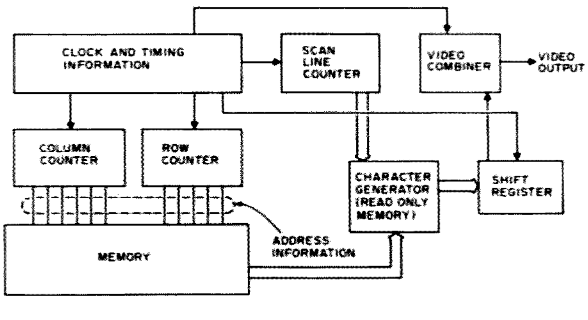

Fig. 1. Video display simplified block diagram.

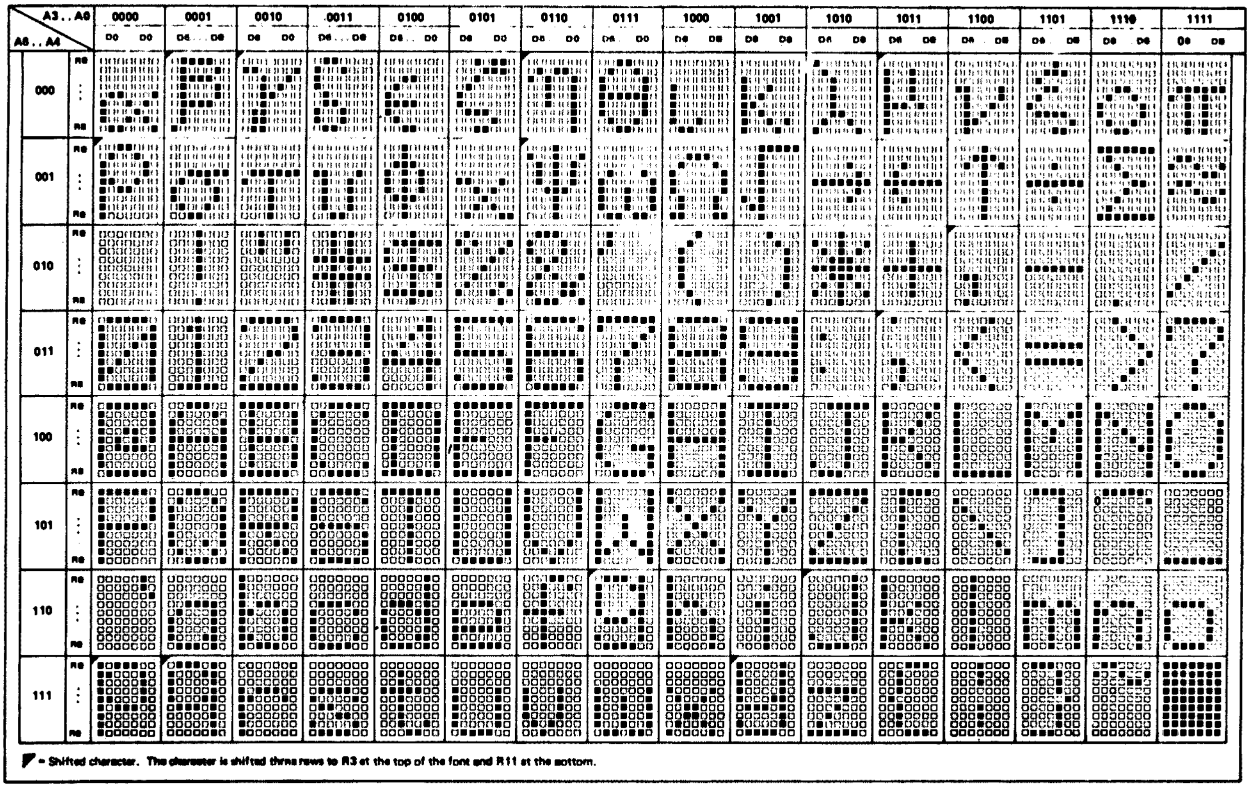

Fig. 2. Character set for the MCM6571A character generator. This read only memory is also available with other character sets.

shifted out to be combined with the horizontal and vertical information to produce white dots on the screen.

My display writes 32 lines of 64 characters per line. I allow 15 scan lines per row of characters. This means that it takes 15 traces of the electron beam to produce one row of characters. A simplified flow of events would be:

1. The system is reset by the vertical sync pulse.
2. Several horizontal sweeps are allowed to happen before anything else to space the characters down from the top of the raster, which is usually distorted.
3. Data from memory is presented to the character generator. At the same time, the scan line counter tells the character generator which row of dots within a character is needed.
4. The output of the character generator is loaded into a shift register and shifted out into the video combiner one bit at a time.
5. The column counter is incremented and the same process takes place over and over until the end of a line.
6. At the end of a horizontal trace, the scan line counter is incremented by the horizontal sync and the same line of characters is presented to the character generator to produce the second row of dots on the screen. This process repeats until the first row of characters has been completed.
7. A few horizontal sweeps are allowed for spacing. Then the row counter is incremented and the above process repeats for the next row of characters (and so on, until all the characters have been completely displayed).

The operation of my display follows this basic outline, except where I have taken advantage of peculiarities within the circuit. I also have had to play tricks because of the interlacing of the two video frames, so that I would have enough scan lines available to produce 32 lines of high quality characters.

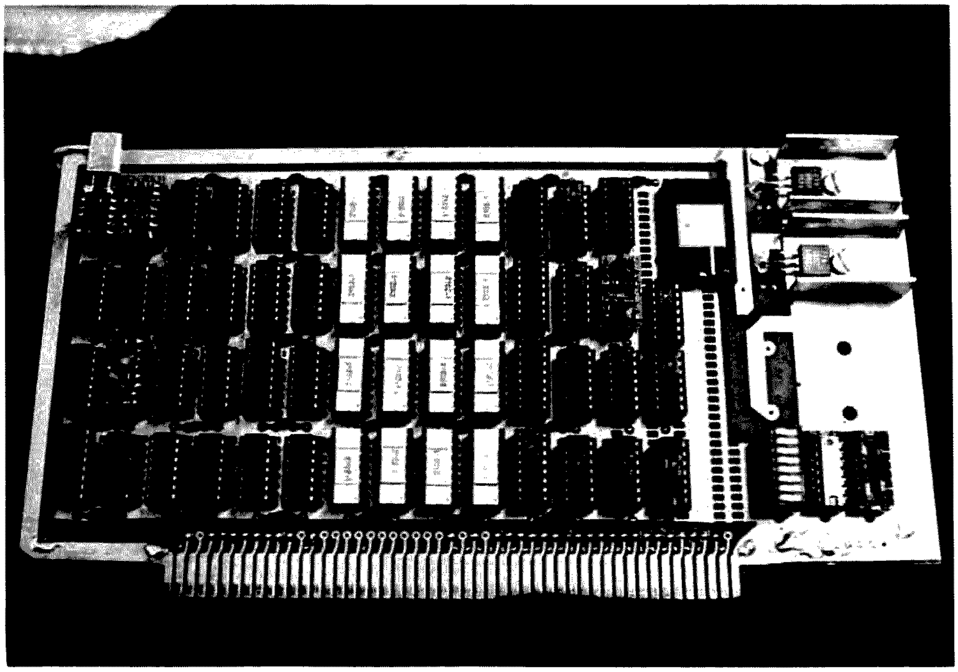
Conventions

For simplicity (at least in the writing of the article, if not in the reading), I have adopted a few conventions in drawing the schematics for publication. First, all crossing lines are *not* connected. Connections are drawn to produce "T" junctions.

A logic gate with an "00" in it is a 7400, one with an "04" in it is a 7404, and so on.

ICs drawn as boxes have their part numbers inside the box.

I have not numbered pin connections on common logic gates; I leave this to the builder, since it is unlikely that his layout will make it convenient to use the same pin numbers. (My display is wire-wrapped. I highly recommend going that way, as a printed circuit layout on this scale would be a great undertaking for the hobbyist.) I have not numbered or shown power connections for any but special ICs. Fig. 3 contains all pin number and power information for the ICs used. Where I have numbered pins on counters, flip-flops, and special ICs, there is little choice (except for the flip-flops which have two gates per package). Numbers in small square boxes refer to Altair bus numbers and are the only off board connections to be made except for the video connection itself. If you are not using an Altair-compatible bus, then you will need to make appropriate corrections to the memory control part of the schematic (note that the only connections to the external world are those appearing on the memory schematic – except for power and the video connection).



Component side of Altair bus video driver board.

The Memory

I'll start my discussion of the actual display circuit by describing the memory schematic shown in Fig. 1, since it is relatively straightforward.

I have used 2102s for memory, since they are cheap and readily available. There is nothing sacred about this choice, and any other memory could be substituted if it were fast enough. I recommend buying memory which is guaranteed to at least 500 nanosecond access time (to insure reliable operation).

The address lines of the memory chips are tied in parallel and connected to the outputs of the 74157 multiplexers, whose function I'll describe soon. Data inputs of the memory are simply connected to the data out bus of the processor. The data outputs of the memory are connected to the character generator (Fig. 5) and to some tri-state bus drivers (74125). The purpose of the tri-state bus drivers is to allow data to be read from the display memory by the processor. If you wish to use another tri-state gate (such as an 8T97), it will make no difference.

The memory control circuit serves to distinguish between valid memory requests and random states of the Altair bus which occasionally look like memory requests if enough care is not taken. The gates in the upper left of the memory schematic decode valid processor requests for the memory by monitoring three status lines and five address lines. If SOUT and $\overline{\text{WO}}$ are both low, then the processor is about to write to memory. If MEMR is high, the processor is about to read from memory. If, at the same time, address lines A11 through A15 are high, then the byte of memory being addressed is within the two kilobytes of display memory. One half of a 7474 flip-flop is used to latch the request status during sync time of the processor, with the Θ_1 clock being used to clock the flip-flop at a time when all address and status signals are stable. While my display memory is located in the high order two kilobytes of the Altair's memory addressing range, it is by no means a sacred choice. You can put your display memory anywhere you wish by appropriate decoding of A11-A15.

When a valid processor request has been decoded and latched, the three 74157 multiplexer chips shift control of the memory address lines from the display's own counters to the computer's address bus. The MWRITE Altair bus signal is gated by the output of the request latch to allow the processor to write data into memory. Similarly, the MEMR signal is gated with the output of the request latch to enable the tri-state bus drivers for a read cycle.

Address bit 2^{10} (from the multiplexers) is used to enable either the high order kilobyte or low order kilobyte of display memory.

When the processor is finished with its request for use of the memory, the multiplexers shift control of the memory back to the display control.

The Character Generator

Before I get into the actual description of the control schematic, I would like to take time to go over the character generator I chose and attempt to explain why I did some of the things I did with the control circuitry.

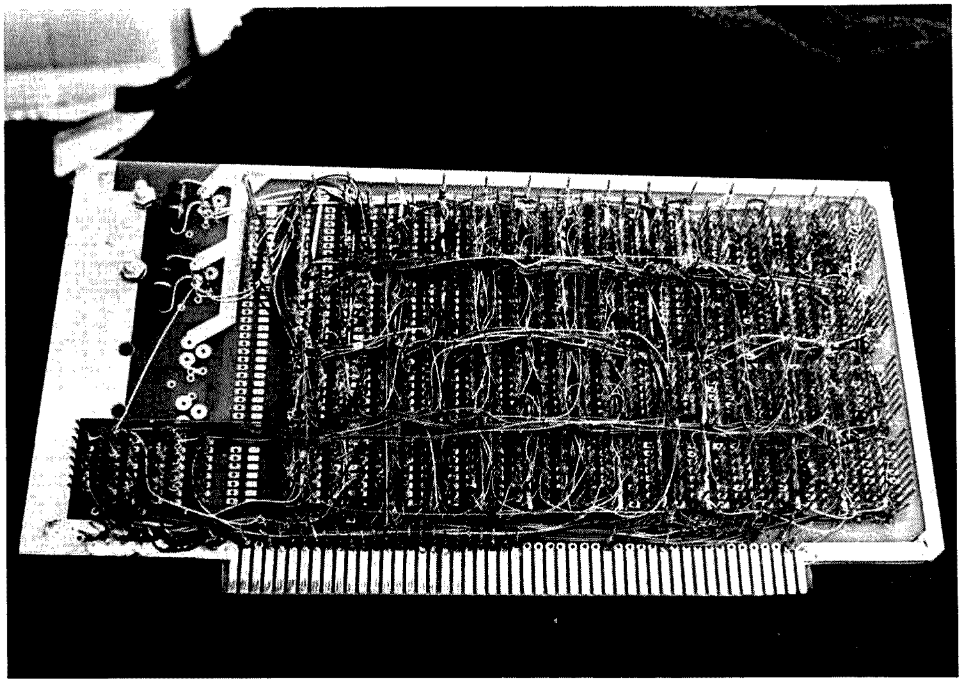
The character generator stores a 7 x 9 matrix of dots for each of its 128 characters. Some of the characters (like j, y, g) should extend beneath the line for best results, so the character generator contains circuitry which shifts the matrix automatically on such characters. What this means is that for a normal character, the dots of the character will appear when lines 0 through 8 of the character generator are addressed. For a shifted character, lines 0 through 2 will come out blank and the 9 lines of the matrix will appear when lines 3 through 11 are addressed. In addition, if lines 11 through 15 are addressed, blanks will result at the output.

What this really means is that from the designer's viewpoint I don't have to know that the information is stored in a 7 x 9 matrix. I can make believe that it is in a 7 x 16 matrix where the last four lines are always blank. Motorola, I love you for the MCM571A!

I use 15 scan lines per row of characters in my display (originally I used 16 but could not achieve 32 lines of characters). Multiply 32 lines of characters by 15 scan lines per character line and you get 480 scan lines (see how nicely the units cancel – high school physics, eat your heart out!).

Now, remember from my earlier discussion that there are only 262½ scan lines per frame. Since I need 480 lines, I must use the fact that alternate frames are interlaced by causing my control circuitry to do every other scan line and alternate between frames. Since I am using 15 scan lines per character line, I must in one frame write the eight even number lines of the first row of characters, then the seven odd numbered lines of the second row of characters, the even of the next, etc., etc.

In the next frame, I must start with the seven odd numbered lines of the first row, the eight even numbered lines of the second, and so on. I



Wire-wrap side of board.

will go low, causing the PAGE ACTIVE flip-flop to be clocked, setting it high.

also have to be sure that I am using the correct frames of the raster to avoid producing some weird characters. It turns out that only about 482 lines of the raster are useful. The rest are contained within the field of the blanking pulses, and attempting to use them results in a rolling display or worse. Otherwise I would have stayed with 16 scan lines per character. I might also mention that the choice of 14 scan lines per character was appealing to me until I tried it and found that the lines began to be uncomfortably close together.

Display Control

Several signals within the control circuitry are important, and discussion of their functions will help to explain the operation of the display control (see Fig. 5). These are PAGE ACTIVE, FIELD INDEX (FI), LINE ADVANCE, END OF PAGE (EOP), END OF LINE (EOL), MASTER CLOCK (MC), VERTICAL DRIVE (VD), HORIZONTAL DRIVE (HD), and COMPOSITE BLANKING (CB). VERTICAL and HORIZONTAL DRIVE are really just vertical and horizontal sync, but the sync generator manufacturer labels them as drive. Any signal shown on the schematic with a bar above it (as $\overline{CB}$ or $\overline{VD}$) is the complement of the signal indicated. The signals VD, HD, CB, and FI originate from the sync generator (Fig. 6). The other signals are generated within the display control.

Sync Signals

I have used a National Semiconductor MM5320N TV camera sync generator to generate timing signals needed to produce a raster. It produces the VERTICAL DRIVE signal, which (along with its complement) is used mainly to reset various counters and flip-flops of the display control. The HORIZONTAL DRIVE output of the sync generator serves the same purpose. The FIELD INDEX output of the sync generator identifies field number 1 of the raster. It is a pulse which occurs for two clock cycles at the leading edge of the vertical blanking for field one. I will discuss the sync generator in more detail when I get to the description of that schematic (Fig. 6), and mention it here only as a prelude to describing the control circuitry.

Page Active

PAGE ACTIVE is a signal which goes high during the writing of a frame of information on the CRT. Thus, it will be low until the electron beam is in position to trace out the top scan line of the first row of characters and it will remain high until the last scan line of the last row of characters has been produced. When it is low, all video output is suppressed and the control circuit is mainly idle.

Here is the sequence of events which results in the clocking of the PAGE ACTIVE flip-flop (which in turn enables the rest of the display):

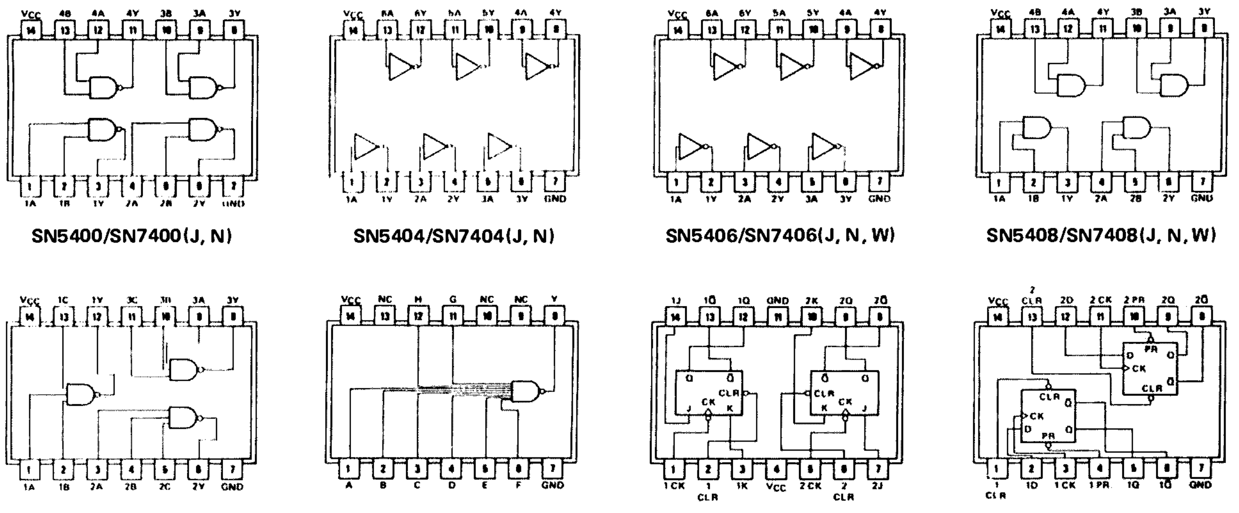
1. $\overline{VD}$ occurs (resetting other things which I will mention later) and causes the scan line counter to be loaded with a five. I will try to explain why I had to do this in a few lines.
2. The CB signal will begin clocking the scan line counter. When this counter reaches seven, the 7410 connected to the A, B, and C outputs of the scan line counter will go low, causing the PAGE ACTIVE flip-flop to be clocked, setting it high.

The reason that I load the scan line counter with a binary five is to cause a fixed number of scan lines to be ignored before clocking the PAGE ACTIVE flip-flop. Remember that I said earlier that only about 482 scan lines were useful? This is because 21 of the 262½ lines per frame occur during the vertical blanking pulse. This leaves only 241½ useful lines per frame. By using the COMPOSITE BLANKING signal to clock the scan line counter, I already ignore the first 21 lines since no clocking of the counter will occur during the vertical blanking pulse. By presetting the scan line counter to five, it will take only a couple of lines to get it to seven where it causes the PAGE ACTIVE flip-flop to come on, thereby wasting as few as possible lines. It turns out that the counter will count the vertical blanking pulse so that I am in fact only wasting about one half of a line at the top of the display. In any case, there are not many lines to waste and this method utilizes the maximum amount of useful raster.

Once the PAGE ACTIVE flip-flop has been set, the row counters and the width counter are enabled (follow the logic on the schematic to convince yourself of this). The PAGE ACTIVE flip-flop is ultimately cleared by the END OF PAGE signal.

Odd/Even Flip-Flop

The FIELD INDEX is used to keep track of which frame is being written at any given time. Remember that I mentioned earlier the necessity to alternate even and odd scan lines of the characters being displayed. The alternation must occur between rows of characters and also between frames. The FIELD INDEX is used to control the starting point of the odd/even flip-flop within a given frame. This is accomplished by



SN5400/SN7400(J, N) SN5404/SN7404(J, N) SN5406/SN7406(J, N, W) SN5408/SN7408(J, N, W)

SN5410/SN7410(J, N) SN5430/SN7430(J, N) SN5473/SN7473(J, N, W) SN5474/SN7474(J, N)

setting the odd/even flip-flop with the END OF PAGE signal. The EOP flip-flop, however, is cleared by $\overline{VD}$, causing the EOP signal to go away at the beginning of the VD pulse. The FI pulse hangs around for a couple of clock cycles after the beginning of the VD pulse, so that if it (FI) is present it will clear the odd/even flip-flop. Thus the odd/even flip-flop will be set or reset at the beginning of a frame.

The output of the odd/even flip-flop serves as bit zero of the line input to the character generator, causing it to generate the appropriate dot information. The output of the odd/even flip-flop also serves to control the number of scan lines allowed for a row of characters by causing the scan line counter to divide by either seven or eight. This is relatively straightforward and I leave it to the reader to verify that this is so by examining the schematic (I always hated it when textbook writers did that to me ... now it's my turn). Upon completion of two complete scans, there will have been 15 scan lines allotted for each row of characters.

Line Advance

The LINE ADVANCE signal is the same as used to enable the PAGE ACTIVE flip-flop, except that once the PAGE ACTIVE flip-flop is set, the LINE ADVANCE will clock the row counters. I had trouble with a glitch on the LINE ADVANCE, so I had to

put in an 820 (or so) pF capacitor to get rid of it.

Row Counter

The row counter consists of a 7490 decade counter and one half of a 7473 flip-flop. The row counter provides the high order five bits of the memory address to the multiplexers.

End Of Page

The EOP flip-flop is clocked by the row counter after 32 rows of characters have been displayed in a given frame. It is used to clear the PAGE ACTIVE flip-flop (which inhibits the world) and also to set the odd/even flip-flop as described above. EOP is reset by VERTICAL DRIVE.

The Character Generator Again

The character generator accepts a row input from the scan line counter to tell it which row of a matrix to present to its output. The character code is the rest of the input to the character generator and comes directly from the memory. The seven bit output of the character generator represents part of the dot pattern of a character and is presented to the 74165 shift register. Clocking of the shift register to dump the dots out in serial fashion is by the MASTER CLOCK. Loading of the shift register is controlled by circuitry associated with the width counter.

Width Counter

The width counter is a 7490 decade counter which is really dividing by nine because of external gating (shown in the schematic). The width counter is held at zero whenever the PAGE ACTIVE line is low. It is also cleared by the COMPOSITE BLANKING to insure that it begins every line from zero.

The width counter is clocked by the MASTER CLOCK and is responsible for determining the number of clock pulses allowed for each character in a row. I have allowed nine clock pulses per character. Seven pulses are needed to display the seven dot width of a character, plus one leading and one trailing pulse to allow for spacing between. I have arranged the loading and clocking of the shift register to achieve both leading and trailing blank dots, as opposed to simply allowing two blank dots between characters. This distinction is not too important when displaying normal video, but when the video is inverted on a given character, it assures that the character will be centered in the field of white.

The D output of the width counter is used to provide a load signal to the shift register. The C output is used to clock the column counters, which count the number of characters per row. Note that the column counters are advanced *before* the shift register is loaded. This is to allow sufficient time for the two memories (the main character memory and the character generator) to stabilize. The data loaded into the shift register will be the data from the last character, because of the memory access time.

Column Counters

The column counter, a 7493 and part of a 7490, counts the number of characters within a row and provides the low order six bits of address information to the memory control board. The column counter is reset by the HORIZONTAL DRIVE pulse to insure that it begins counting at zero for each row. The C output of the width counter is used to clock the column counter as discussed above.

One half of the 7490 used in the column counter is a divide-by-four counter, while the other half is used as a flip-flop. To see this, note that the D output of the 7493 is connected to the B clock of the 7490 (the B clock is the input to the divide-by-five stage of a 7490). The C output of the 7490 is used to clock the A input, which will cause the A output to go high after the fourth time the B input is clocked. The A output is connected in turn to the J input of the END OF LINE flip-flop. The END OF LINE

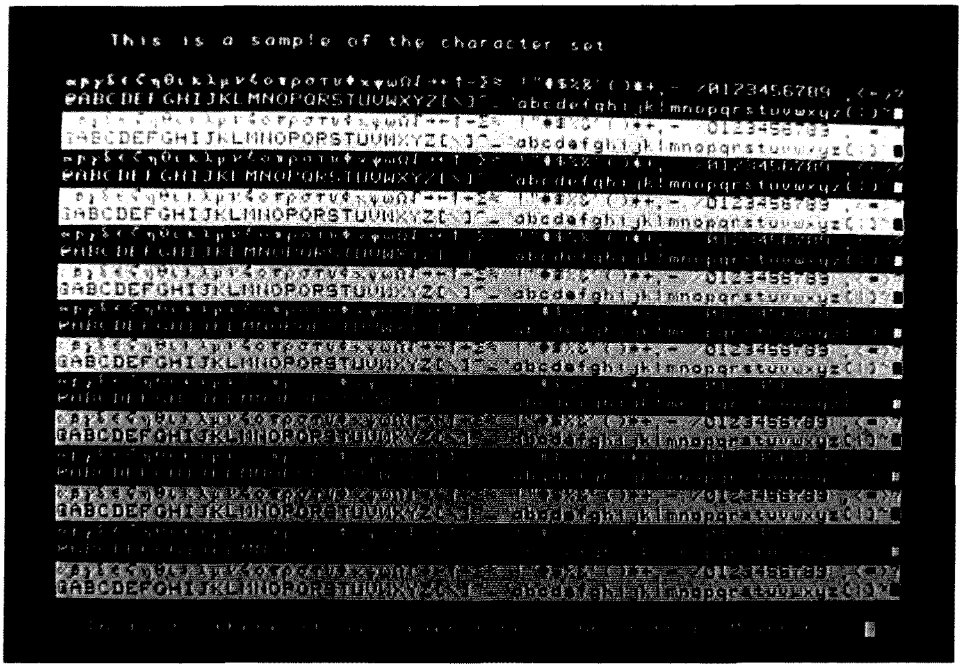
7430	14	7

Fig. 4. Schematic diagram of memory circuits.

flip-flop will be clocked on the falling edge of the D output from the width counter. The output of the EOL flip-flop then inhibits any further loading of the shift register, hence ending the current line.

The reason for all this playing around with the column counter is to allow the last character to be loaded into the shift register. If you remember the discussion about the column counter being clocked to the next character before the data from the current character is loaded into the shift register, you will see that the column counter will be at 64 (representing the 65th character since the counters start at zero) when the load pulse for character 63 (the 64th character) occurs. Since I have to allow the 64th load pulse to occur, I came up with the above scheme to delay the clocking of the EOL flip-flop.

I might mention at this point that there is really no good reason to bother using the C output of the 7490 to clock the A input. The internal D flip-flop of the 7490 is already clocked by the C output, so the D output could serve as the J input to the flip-flop. In fact, by gating together the D output of the 7490 section of the column counter with the D output of the width counter (using a 7408 AND gate with the output of the AND gate clocking the A input of the 7490), the EOL flip-flop could be eliminated, the A output of the 7490 replacing the EOL signal. But you would have to use a NOT gate to derive $\overline{EOL}$ and then you would have one half of a flip-flop left over elsewhere. I mention this possibility partly for the benefit of anyone who might be making changes where it would be nice to have an extra flip-flop, and partly to illustrate that there is nothing sacred about the way I have done things. As long as you understand the purpose of each



Character set.

part of the circuit, you can modify it to suit your particular requirements or supply of parts.

Video Inversion

The Invert Video flip-flop controls inversion of the video signal to produce a black character within a field of white. Note that by inverting the video, I am referring only to inverting the character part of the video, not the sync and blanking signals.

The video may be inverted character by character, allowing the use of multiple cursors (I use an inverted blank for a cursor) or techniques such as inverting important messages (or flashing them between normal and inverted video). The display also makes a dandy checkerboard. The eighth bit of the display memory is used to control the state of each character.

Since the memory has already been advanced to the next character during the time in which dots for a given character are being drawn by the electron beam of the CRT, it is necessary to latch the eighth bit of memory in the Invert Video flip-flop. This bit is clocked into the flip-flop at the same time the load pulse for the shift register goes high. The outputs of the flip-flop control a multiplexer made from 7400 gates, thereby selecting either the Q or $\overline{Q}$ output from the shift register. The Invert Video flip-flop is forcibly cleared after the EOL signal comes on (EOL and the D output of the width counter are gated to produce a clear pulse), to assure that the brief part of a line traced by the electron beam after the last character is blank.

Note that the output of the video inversion multiplexer (the 7400 gates) is clocked by the MASTER CLOCK. The main reason for this is to eliminate the possibility of generating a wide video pulse (the top of a "T" or an inverted blank would be examples) which would cause the trace produced by the electron beam to bloom or, at the very least, appear brighter than other parts of the display. Clocking the video makes all video pulses the same width (the top of a "T" would come out as seven consecutive short pulses rather than as one long pulse) and results in a very uniform brightness over the entire display.

Video Inhibit

The Video Inhibit flip-flop prevents generation of random video pulses which would otherwise result from decoding of wrong information by the character generator during times when the processor is using the display memory. Whenever the processor makes a request for the memory (as indicated by the CPU REQUEST signal from the memory control schematic), the Video Inhibit flip-flop is cleared. The Video Inhibit flip-flop inhibits further loading of the shift register and forces the Video Invert flip-flop to the off state the next time it is clocked. Once the processor request has been cleared, the Video Inhibit flip-flop will be clocked by the end of the next load pulse, setting it back to normal. Note that the load pulse which clocks the Video Inhibit flip-flop will be ignored by the shift register, since it does not clock the flip-flop until the trailing edge. The next load pulse will cause the shift register to be loaded. The result is that video is inhibited during pro-

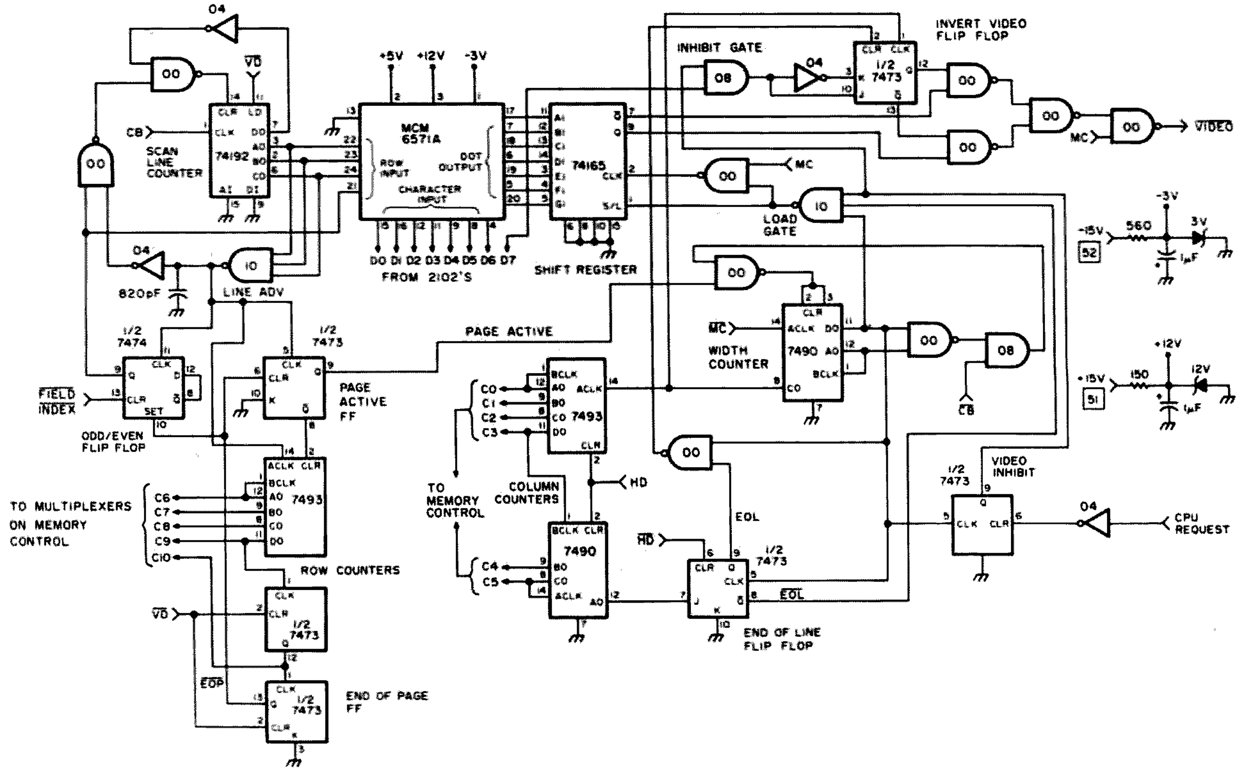


Fig. 5. Schematic diagram of display control circuits.

cessor requests for memory and for at least one complete character cycle after control is restored to the display (to assure that the memory is back in step with the display control).

The loss of a row of dots from random characters around the screen during processor requests is not a problem, since it is hard to notice the absence of a single row of dots within a single character for 1/30th of a second. The only time that the display is noticeably degraded is when the processor is making requests at a very rapid rate. But the rate is so great that it would not be possible for most people to read the display anyway.

One instance where the degradation of the display caused by cycle stealing becomes noticeable is during a line feed. The line feed (or scroll) is a software function and involves reading and rewriting almost all 2048 characters of the display. The process is very fast (50 to 100 milliseconds, depending on your software and memory cycle time) and results in a noticeable display degradation because of the large number of requests within a short time. But the degradation during a line feed is not a problem since the display would be non-readable during a line feed even if it was not degraded. Also, it happens so fast that one does not really perceive the display to have lost anything unless he is really looking for it.

One other thing to remember (to prevent heart seizure the first time it happens) is that if you stop the processor and examine the contents of a location within the display memory, then you are in effect requesting 100 percent of the memory's time, resulting in a completely blank display.

Sync Generator and Video Combiner

The sync generator schematic includes the MASTER CLOCK and the video combiner. The MASTER CLOCK is a simple oscillator made from 7404 gates, a few Rs and Cs, and a 12.6 MHz crystal.

The National Semiconductor MM5320 sync generator requires a 1.26 MHz clock, so I divided the 12.6 frequency by ten. Note that the 7490 is used as a symmetrical divide-by-ten counter by going through the divide-by-five stage and then into the divide-by-two stage.

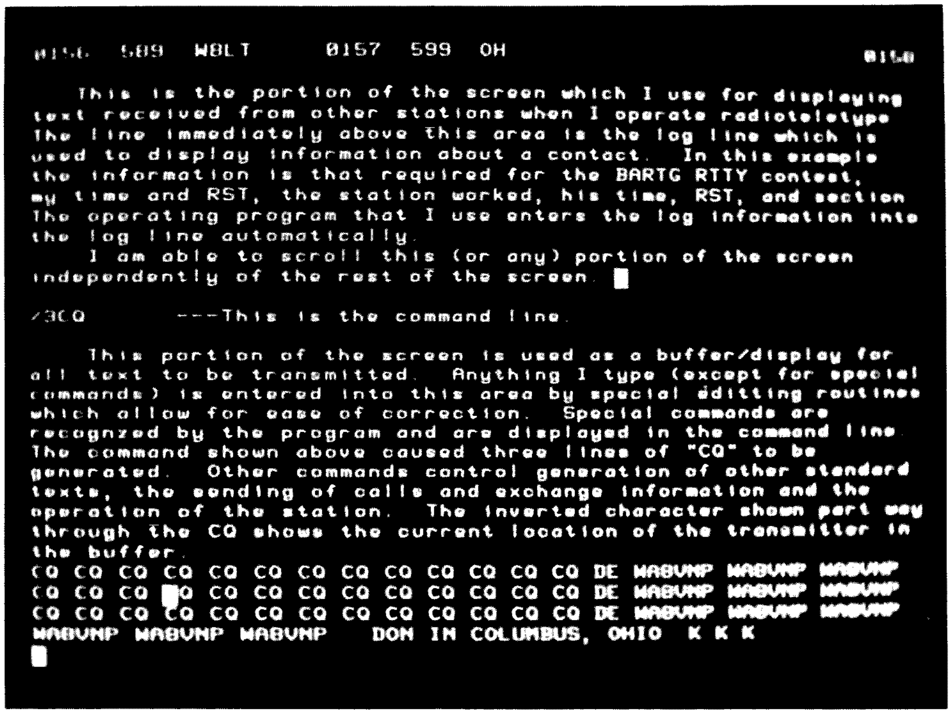
I have buffered all outputs of the 5320 except the FIELD INDEX output, which is only connected to one gate anyway. As I discussed earlier, the sync generator does all the timing necessary to generate the appropriate sync and blanking signals to produce a raster.

Putting the COMPOSITE SYNC, COMPOSITE BLANKING, and VIDEO (from the display control schematic) to form a single video signal is the function of the video combiner. The video combiner is built from 7406 open collector inverters and some diodes. The resistors shown at the junction of each of the 7406 outputs and its respective diode determine the weight of the given signal. The resistors I have shown are not too critical and may be changed for best results. The resistor for the blanking component is chosen to produce about a .2 to .3 volt change in the output level when the blanking turns on and off. Similarly, the sync component should be around .7 volts and the video component should be a couple of volts (or whatever produces good contrast). These values seem to work well with the monitor I use, as it has a 75 Ohm input impedance.

The video monitor shown in the photographs is a Motorola M2000-1SC. It is a good quality nine inch monitor having a bandwidth of about 12 MHz. If you plan to use an old black and white TV, you may experience problems with overscan (which is built into most TV sets to make the picture look bigger) or bandwidth. The Motorola monitor costs around $115, but is well worth it for this application.

Power Supplies

The logic components will



Radioteletype contest program example (note multiple cursors).

require a good five volt supply. I used two 7805 regulators (the same as used by MITS and other Altair board manufacturers) to regulate power from the Altair bus. I use one for powering the memory and one for the logic. Be sure to install plenty of .1 uF capacitors at various points on the board, to prevent noise problems from messing up the display. If you are building the display for use outside an Altair type computer, I will assume that you can also manage the power supply.

Various other voltages required by the sync generator and character generator are provided by the zener diode regulators shown on the schematics. The amounts of current needed at these voltages are very small.

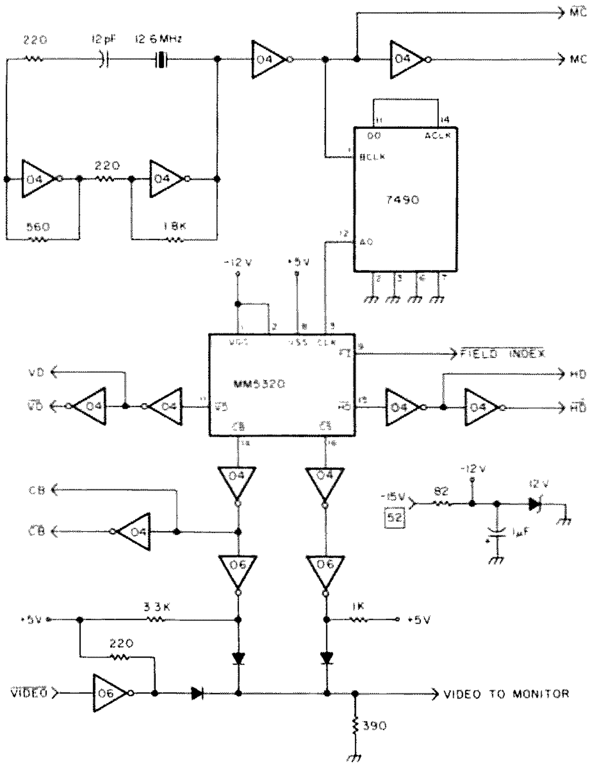


Fig. 6. Sync generator, video combiner, and clock circuits schematic diagram.

Use of the Display

The various pictures of the display show several ways for utilizing the display. I will let you read the captions rather than repeat them here, and will try instead to present a few simple ideas to get you started.

The first thing is to think of the display as a window to memory rather than as an output device. Any manipulation of data on the display (writing, erasing, updating, scrolling) involves a software process to put the desired information into the right location within the memory. There is no line feed function, nor are there any cursor positioning functions. Characters are simply stored at the correct locations. Cursors, if used, are simulated by appropriate software for the benefit of the person looking at the display. This allows the display to be configured any way you see fit. Some of the photographs depict displays where my Altair was being used as a terminal to a DEC PDP-10. A simple program was written which made the display behave as though it were a Hazeltine 2000 video terminal. But if you read the text in the picture of my radioteletype application, you will see that the display is being used in a way few, if any, other displays or terminals could duplicate.

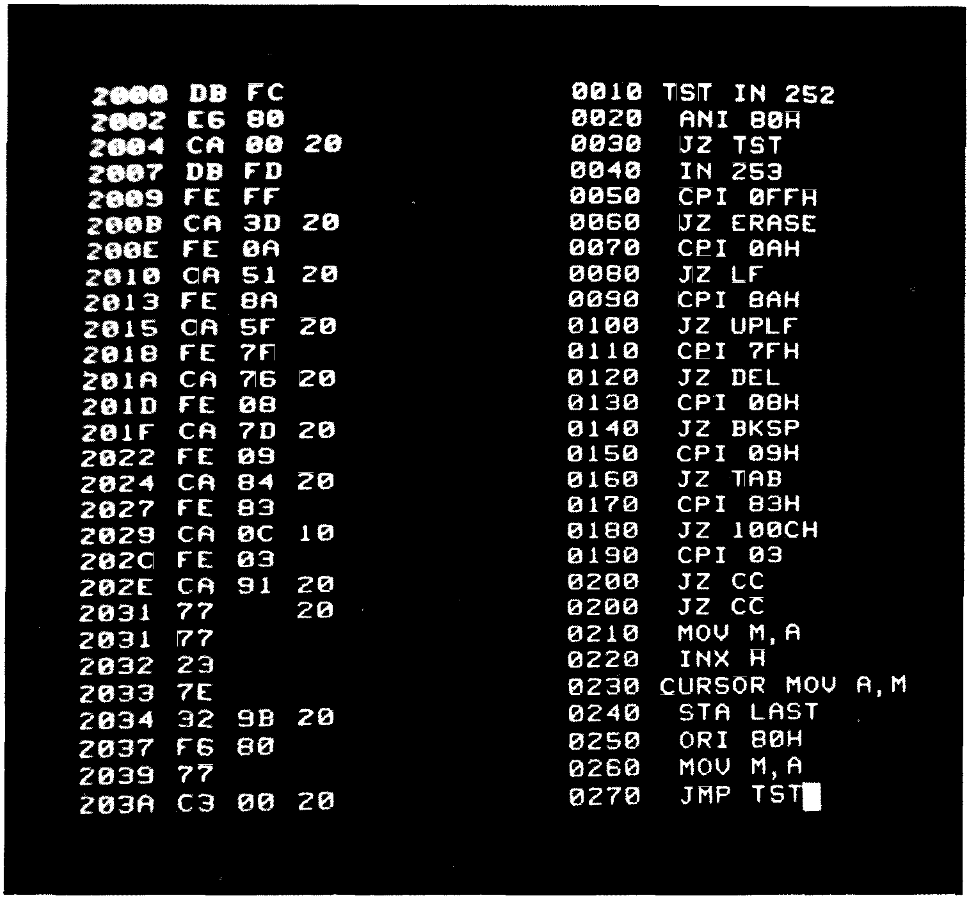
Some specific methods to accomplish normal functions are:

1. ERASING – Simply store blanks throughout the display memory. Note that selective erasing is just as easy.
2. SCROLLING – Read a character from the second line and write it back in the same location on the first line (i.e., move it back 64 places). Continue reading and writing characters until you have rewritten the last line into the second to last line. Then erase the last line. Note that it is a simple matter to scroll only a part of the display instead of all of it.

Construction Ideas

Before you begin building the display, you should make copies of the schematic and make any changes you think necessary to adapt the display to your system. Then assign numbers (or letters) to all of the ICs and number the pins. If the IC numbering scheme is devised to represent a socket coordinate, you will have less trouble when you begin to wire-wrap the board. Then make all power and ground connections. Then finish the

Example of split screen capability.



board by making all wraps associated with a node on the schematic at the same time, indicating (by small colored slashes or otherwise) that you have completed a node.

Testing

There is very little I can mention here, as there are so many things that can be wrong from a misplaced wire-wrap. I suggest checking the sync generator to be sure it is working and then proceeding to the various counters and flip-flops to see which are working. The memory may be tested for proper operation by writing a memory diagnostic program. Obviously, for any real trouble-shooting or debugging you will need an oscilloscope — and you will need to be able to think through the operation of the display. Beyond this, I think I would be writing in vain except for saying, "Good luck!" ■

New Products

from page 27

repeater operation will stretch below 146 MHz. The FCC's intent to deregulate is clear with Docket 21033, and if it does become law, operating requirements for 2m FM will radically change.

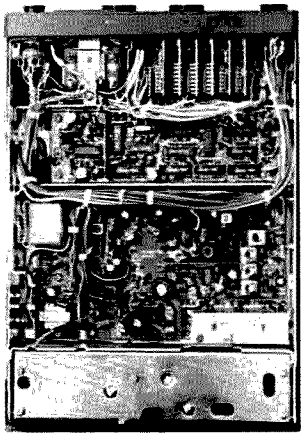
It will be necessary for 2m FM rigs to cover the *entire* band, not just the current repeater segments. Squelch systems employing continuous tone, tone burst, and the variations that go with them will become essential for accessing repeaters and repeater links. It may not be long before repeaters will have multiple links: 2 to 20m, 2 to 40m, and so on. The dream of driving across town working Europe or Australia via a 2m to 20m link might not be a dream much longer. (Wayne Green did it years ago here in Peterborough before the FCC outlawed it.)

One 2m FM rig capable of handling the new repeater revolution *now* is the Kenwood TR-7400A. It covers the entire 2m band and offers one of the most flexible squelch systems going — continuous tone-coded squelch (encode and decode or encode only with common frequency active filters), tone burst, and normal carrier squelch. The TR-7400A is delivered set up for normal carrier operation, with a series of optional modules available for the other squelch modes. A front panel selector switch allows for all three variations with an LED indicator to remind you when the TR-7400A is in the continuous (encode and decode) tone-coded mode. Kenwood has tried to eliminate the characteristic time lag in tone squelch circuits through the use of an active filter. Other squelch modes selected from the same control include tone burst and subaudible (encode only) tone. In all, Kenwood offers 25 different modules covering the tone squelch and tone burst modes. Only one frequency of each type can be used at a time, but the use of computer type connectors would allow easy modification for outboard selection of several different frequencies.

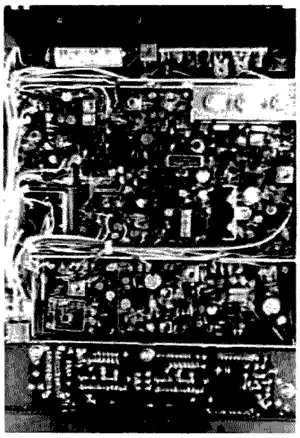
Back to that price war I mentioned earlier. Kenwood had originally announced the TR-7400A in the $450 to $550 price class. Considering its features (PLL synthesized, 25 Watts, full 2m coverage, digital readout), that sounds about right . . . right? Wrong! When the units began to trickle into dealers just after Christmas, the price tag was down to $399 and the war was on.

It's not hard to understand why Kenwood is finding it hard to keep up with demand. The TR-7400A offers you a lot for your money. Aside from the unique squelch design and full coverage synthesizer, Kenwood decided to go beyond the normal 10 Watt output of most transceivers. Despite published specifications of 25 Watts out, the TR-7400A delivered more than 30 Watts into a 5/8 wave antenna, and the low power position yielded 5 Watts out. I was easily able to adjust low power up to ten Watts and drive my 10 by 70 Watt amplifier (a necessity in the low lands up here). In most cases, I found the 25 Watt position more than adequate to access repeaters I couldn't use with 10 Watt rigs, but it was real nice to have three levels of power to choose from. Kenwood uses the Motorola MRF-208 as a driver, and the 2N6083 for the final, which may explain the massive Motorola-like heat sink. The finals are protected by *reducing* output when faced with impedance mismatches, instead of shutting down the radio completely. The front panel meter reads output, so just operating the Kenwood will tell you something about your antenna system. According to the manual, a reading of 8 in the high power mode on a scale of 10 indicates an swr of less than 1.5:1. Low power, factory adjusted for 5 Watts, reads a 3 on the meter scale. Tests with antennas purposely put out of tune reduced high power output to as low as 5 on the meter without excessive heat or transmitter shutdown.

Audio reports were good, with many stations responding that the Kenwood's talk power exceeded everything else on frequency. A deviation meter showed plenty of audio to spare; the 5 kHz spec proved to be quite conservative for my voice characteristics, and the mike gain had to be adjusted. Quality-wise, the Kenwood's audio drew compliments, although several other TR-7400A users objected to the factory supplied dynamic microphone, claiming it was too small for comfortable operation. It took a bit of getting used to, but the palm-size mike actually became preferable after a period of time. (Other large microphones were tried, but reports did not indicate any change in the audio level or quality.) Hooking up a touchtone pad couldn't be easier, since Kenwood included side panel jacks (mini type) for pad input and external speaker output, thus eliminating the need for hard to connect octal type sockets. (Ever tried to put your radio in the car at night and line up those darn pins without bending them?)



TR-7400A, top view. The shielded compartment houses the final amp.



The TR-7400A, bottom cover removed. Squelch modules go into computer connector near the ceramic filter.

The TR-7400A synthesizer is the phase locked loop (PLL) type, with LEDs for digital readout. The PLL divides the 4 MHz bandwidth into 400 channels every 10 kHz, with a push-button 5 kHz offset. Two frequency selector switches allow 100 kHz and 10 kHz switching respectively, with a four position switch for choosing band segments. A three position switch sets transmitter offset at 600 kHz up or down, plus simplex. A dual concentric volume-squelch control completes the package.

One way to measure a mobile radio's quality is what happens when the lights go out . . . can you use it in the dark? Or do you have to pack a flashlight to find out what frequency you're on? Not with the Kenwood. *Every* switchable function, from the synthesizer to the various squelch modes, has its own LED indicator. Six bright red 1" high LEDs tell you what frequency you're on, another LED indicates when you're transmitting, while still another warns that the synthesizer PLL has unlocked and the radio has automatically shut down. The TR-7400A even indicates what transmitter offset you're using, with an LED showing red for -600 kHz, green for +600 kHz, and no indication when in the simplex mode. What all this means is that the Kenwood makes after dark mobiling a snap — no fumbling, no confusion to take your attention off the highway. After a few hours of operating the radio, it only takes a quick glance to see what frequency you're on, what offset you're using, and which squelch mode is engaged. During daylight operations, you won't have to squint to read the LEDs; all controls are well calibrated independent of the LEDs and are easy to find by touch. Counting from one repeater pair to another is made simpler by Kenwood's use of stops on the frequency selector controls, allowing you to only go once around before being forced to reverse direction.

As previously mentioned in these pages, my car suffers from a bad case of ignition noise. I've tried a number of "cures" with mixed results, and have come to accept that weak signals will have to be passed by until warmer weather allows a new assault on the MGB. Kenwood included a well-bypassed power input and it seems to work; my ignition noise is clearly lower with the TR-7400A than previous 2m rigs I've had in the MGB.

You may be wondering by now . . . what about the receiver? A glance at Kenwood's specifications on the TR-7400A shows impressive figures: more than 0.4 uV sensitivity for 20 dB quieting, image rejection of more than 70 dB, and spurious interference down more than 60 dB. The radio's performance certainly backs those claims, with trips into Boston, Hartford, and New York revealing no problems with desense and intermod. The sensitivity, compared to other current rigs, is highly competitive. Kenwood uses a double conversion superheterodyne with a 10.7 MHz 1st i-f, and a 455 kHz 2nd i-f. Large helical resonators, a 10.7 MHz monolithic crystal filter, and a MOSFET front end are also used.

In the mobile, the sensitivity and noise filtering add up to a surprising combination: strong, clear signals whether the strength is S1 or against the pin. There's plenty of audio on receive, more than enough to drive a good size remote speaker . . . or the one Kenwood built in. And unlike many squelch circuits I've used lately,

Kenwood's new TR-7400A 2m transceiver.

dynamic range was outstanding, allowing me to squelch out unwanted repeaters that other radios received with the squelch fully engaged.

The TR-7400A comes complete with mounting bracket, microphone, and power cable. The mount is unique, with guide slots on both sides of the radio, and clamp snaps to secure it. Hasplike protrusions extend from the sides of the radio, allowing you to padlock the rig into the car if desired. Most users will probably choose to take the TR-7400A with them, and the bracket makes for easy removal. The device includes an angle adjustment, allowing for tilting the radio in accordance with your dashboard. By some standards the Kenwood is large, measuring just over 7 inches wide by 3 inches high and just over a foot deep. It weighs about 6 pounds, but I had no trouble mounting it in my small sports car (as the photograph indicates) and did not find its size or weight objectionable. To the contrary, the TR-7400A is a high quality radio in the best Kenwood tradition (a tradition established by the TS-520 and reinforced by the TS-820). At a price under $400 it would be less than honest to deny Kenwood's new 2m radio is one heck of a deal . . . in fact, it's a steal! *Trio-Kenwood Communications, Inc., 116 East Alondra Blvd., Gardena CA 90248.*

HEATHKIT HD-1982 MICODER™

The process of using repeater autopatch facilities while mobile has always been a frustrating experience. Between holding in the mike button, grappling for the tone pad, and attempting to continue to drive the car, it often seems like at least three hands are needed.

The Heath Company has vastly simplified the situation through the introduction of their HD-1982 Micoder. At first glance, the unit looks like a standard microphone, but the surprise comes in turning it over. Built into the back is a miniature tone pad. Suddenly, making a call from the ol' buggy is a much easier process.

The Micoder is an easy one evening kit. Although assembly is not too difficult, it does require a steady hand and a light touch since the parts are crowded together on a rather small circuit board. The circuit consists of four ICs, a few resistors and capacitors, and an LED. By the time you add the microphone element, 9 volt battery, and tone pad, you end up with a packed case, giving you a handful that's just a hair larger than most mikes.

The circuit is simple and straightforward. The tones are generated by two NE555 timers, one for high tones, one for low. The pad itself is a miniature tactile type that makes it easy to be sure that you actually hit the button. Another little extra is an LED above the pad that tells you that a tone has been generated. Warning . . . be *very* careful when bending the LED to fit it into the circuit board. I broke two of them.

The microphone itself has not been skimped on. In fact, this high impedance capacitor type with built-in audio amplifier is better than standard mikes supplied with many rigs. When the pad is being used, the mike is automatically disconnected from the output circuit.

Heathkit's HD-1982 Micoder.

After construction, one of two methods can be used for alignment. By far the easiest is the use of a frequency counter. Two miniature pots are used to set the high and the low tones, a process that only takes a couple of minutes.

For those without access to a counter, method two is a little more complicated. It requires access to a repeater site receiver with tone decoding circuits. In that way, tones are set by trial and error.

The Micoder worked famously the first time it was hooked up. I ran into no problems accessing and using the autopatch of the Keene NH repeater. Reports of crisp audio were received. Best of all, I was able to drive safely while punching up the number.

The Micoder can be mated to just about any transceiver on the market with a low impedance input. It worked well with several rigs owned by *73* staffers.

In our age of increased miniaturization and utility, the Micoder continues with the trend of smaller, lighter, and easier to use mobile equipment. The price of $49.95 is quickly repaid in both safety and convenience. *Heath Company, Benton Harbor MI 49022.*

HAM RADIO CENTER'S HAM KEYS

With the granting of Novice privileges to Technician class licensees, the Novice bands have become considerably busier. Manufacturers are doing a booming business in high band transceivers and related accessories, including keys.

The Ham Radio Center in St. Louis MO manufactures a line of keys that are called, interestingly enough, the Ham Keys. There are two basic models, the HK-1 and the HK-3. The HK-1 is a dual lever squeeze paddle designed for use with any electronic keyer. The paddles are easily adjustable for personal preference of contact spacing and can be reversed for wide or close finger spacing. The HK-3 is the old standard straight key. This deluxe model is a smooth performer and worked extremely well at the close contact spacing that I like to use.

Both the HK-1 and the HK-3 are mounted on heavy cast iron bases with rubber feet that keep them solidly planted without the need for attaching them to a table or an ugly piece of board.

Variations on the same theme are provided by the model HK-2, which is simply the squeeze key without a base, and the HK-4, which has both the straight key and squeeze model mounted together on a large heavy base.

The Ham Radio Center also markets the Ham Keyer, the model HK-5 electronic keyer. This little unit features an iambic circuit for squeeze keying, self-completing dots and dashes, and dot memory. It can be operated by the built-in battery or external power, has built-in sidetone, and can be used for grid-block or direct keying.

Unlike many other manufacturers, the Ham Radio Center doesn't have a bewildering array of similar models. The Ham Keys and Ham Keyer are simple and solidly built, an investment that should last for years. *Ham Radio Center, Inc., 8340-42 Olive Blvd., St. Louis MO 63132.*

NATIONAL SEMICONDUCTOR TO MARKET DIGITAL CLOCK MODULE FOR AUTOMOTIVE, AVIATION, AND MARINE USES

A new 12 volt dc digital clock module intended primarily for automotive applications has been added to National Semiconductor's line of digital timekeeping modules.

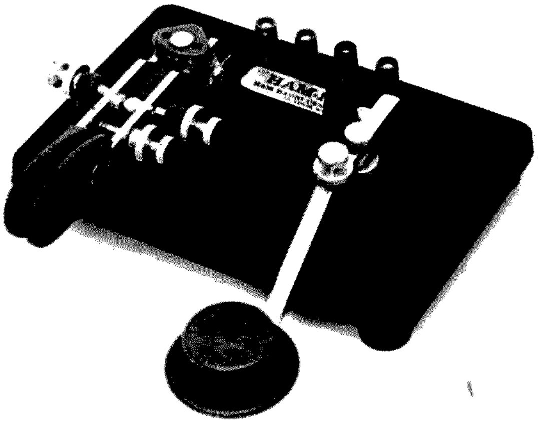
According to module products marketing manager Jerry Zis, the clock module, which is fully protected against automotive transients and battery reversal conditions, is ideal for use in manufacturer-supplied car dashboard clocks, after-market clocks for autos and recreational vehicles, in aircraft and marine clocks, and in 12 volt dc and portable and battery-powered instruments.

Known as the model MA1003, the module is a complete digital clock for all 12 V dc uses. It employs National's model MM5377 monolithic MOS-LSI clock circuit, along with a 4 digit 0.3 inch green fluorescent display, a 2.097 MHz crystal, and supporting components.

"The new module joins National's existing line of digital clock modules for clock radios, alarm clocks, and instrument panels," Mr. Zis said. "With the MA1003, all you need are a few switches and a lens to have a complete ready-to-use automotive clock."

The device features low standby power consumption, an internal crystal timebase, and an automatic display brightness control logic that blanks the display when ignition is off and reduces brightness to one-third when park or headlamps are in use, also following the dash lamp dimming control setting.

Timing accuracy is excellent, typically within one-half second per day, or only a quarter of a minute per month. The display features leading zero blanking and has a blinking colon activity indicator. Display color is filterable to blue, blue-green, green, or



Ham Radio Center's HK-4. Note the heavy cast iron base.

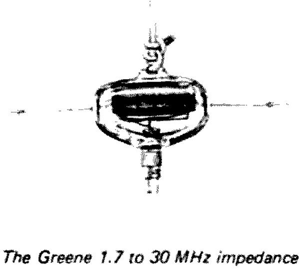
The National Semiconductor digital clock module.

yellow shades. In order to prevent tampering, the hours-advance and minutes-advance switches are disabled when the display is blanked. With ignition or lights off, the display turns off but can be activated by closing a switch. This feature minimizes power consumption in portable applications. A built-in 6 pin edge connector allows easy interconnection to the module.

The MA1003 12 V dc automotive clock module, priced at $25 in lots of 100, is available from stock through National Semiconductor Corporation and its franchised distributors. *National Semiconductor Corporation, 2900 Semiconductor Drive, Santa Clara CA 95051.*

GREENE INSULATOR AIR WOUND TRANSFORMER

Greene Insulator has introduced a new air wound transformer that doubles as the center feedpoint for wire antennas. This device is destined to replace the old egg insulator/taped coax mess that usually adorns the feedpoint of amateur dipoles and inverted "V" antennas. The transformer, which is air wound with #14 wire, not only provides a 1:1 impedance match between antenna and 52 Ohm coaxial cable, but also serves as the "start point" for any wire antenna. The Greene transformer is constructed of high impact polystyrene, and is virtually indestructible. The face of the 4" x 3" "egg" is clear, allowing the user to see the coil inside. An eyelet is moulded into the top for easy antenna support (handy for inverted "V"s), and the coil is terminated with a standard PL-259 connector, complete with waterproof gasket. It is impossible for this device to leak. The ends of the coil extend about two inches from each end of the transformer, and consist of hard drawn #12 copper wire with hooks at the end, ready to be soldered to the antenna sections.



The Greene 1.7 to 30 MHz impedance transformer.

In actual use, the transformer worked well. The device was tested with a long wire inverted "V" beam on twenty meters, and no tune-up or operating problems were observed. One operator indicated that the receiver noise level was lower when using the antenna with the Greene transformer, as compared to one with an unbalanced coax feed arrangement. Possibly this was due to decreased outer shield pickup in the antenna system using the Greene transformer, which allows the dipole to be correctly driven as a balanced device. By any standards, the Greene air wound transformer performed exactly as advertised, and no problems were encountered. *Greene Insulator, W1-CPI, 3 Pilgrim Drive, Bedford NH 03102.*

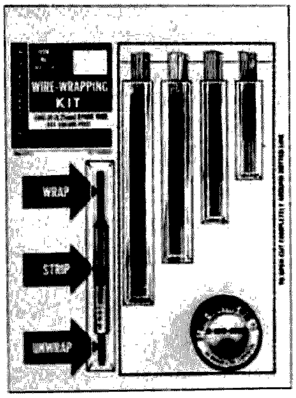
THE SYSTEM 4000

A computer system designed specifically for the ham operator has finally been developed. Curtis Electro Devices, Inc., has introduced their SYSTEM 4000, a turn-key minicomputer consisting of CPU, keyboard, 1K of RAM, input and output ports, and TTY serial interface. The system also has provision for up to 8K of ham applications programs, which are contained on PROM. The self-contained system also has provision for accepting four additional PC cards, compatible with the popular Altair bus.

The system presently supports the following programs: an automatic Morse code reader (6-300 wpm), a software paddle keyer, a keyboard keyer with 200 character buffer, and a full or half-duplex ASCII terminal. The monitor device, a TVT or Teletype, is not included with the basic computer. General programs such as an 8K BASIC are also available.

A general ham applications module is also available for those already owning a computer capable of supporting the Altair bus system. This module supports the features of the SYSTEM 4000, and is called the HAM-S100.

The devices are available from *Curtis Electro Devices, Inc., Box 4090, Mountain View CA 94040, (415) 964-3136.*



OK Tool's new Wire-Wrapping Kit.

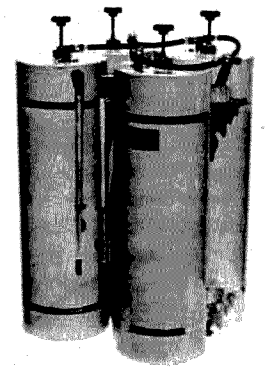
OK TOOL WIRE-WRAPPING KIT

OK Tool's new Wire-Wrapping Kit features selected items of particular value to the prototype engineer and hobbyist alike. It includes a unique new wire-wrapping tool, a roll of wire-wrapping wire, and pre-stripped wire in 4 popular lengths.

The tool, Model WSU-30, is a combination tool that wraps *and* unwraps 30 AWG (0, 25mm) wire on .025 (0, 63mm) square pins, *plus* strips 30 AWG wire using handy built-in stripper. The wire is top quality Kynar® (Pennwalt) insulated silver-plated copper. Supplied in the kit are a 50 ft. (15m) roll plus pre-cut and stripped wire in insulated lengths from 1-4 inches (25-100mm) stripped 1 inch (25mm) on each end. Available with blue wire as Model WK-2B, white wire as WK-2W, yellow wire as WK-2Y, and red wire as WK-2R. Conveniently packaged and available for immediate delivery from *OK Machine and Tool Corporation, 3455 Conner Street, Bronx NY 10475.*

BpBr CIRCUIT DUPLEXERS

Wacom Products, Inc., of Waco TX has announced a new line of duplexers which include the use of a new exclusive circuit developed by the company. When used with a high Q filter, the "BpBr Circuit" provides superior suppression of spurious and sideband noise between and adjacent to the duplex frequencies, particularly when the duplex frequencies are close spaced. A patent is pending on the new circuit.



Wacom's Model WP-641.

Model WP-641 consists of four 8" OD cavities with the BpBr Circuit and is designed for use with duplex stations in the 144-174 MHz band when the Tx to Rx frequency separation is 500 kHz or more. It provides bandpass characteristics near the pass frequencies and band-reject cavity characteristics at the frequencies to be attenuated. Superior Tx to Rx isolation is a feature of the new model.

For additional information contact *Wacom Products, Inc., P.O. Box 7307, Waco TX 76710.*

YAESU SERVICE MANUAL AVAILABLE FOR FT-101 SERIES

A 200 page technical service manual, written in layman terms, covering the various models of the FT-101 series transceivers, is available from Yaesu Electronics Corporation of Paramount, Calif., and their dealers throughout the United States.

Available in February, 1977, it is priced at $25.00 U.S. dollars, F.O.B. Paramount. Send orders to (or you may contact their U.S. dealer organization): *Yaesu Electronics Corporation, P.O. Box 498, 15954 Downey Avenue, Paramount CA 90723.*

Save Time with a Micro OS

-- isn't that what computers are for?

So what's an operating system (OS) and why do I need one? I don't actually know the "dictionary" definition of an OS, but my understanding is that an OS is rather similar to the family of programs we commonly call monitors, except an OS is much more powerful and has more bells and whistles. The Mikbug* monitor in the SWTPC M6800 is an example of a nice little monitor; it removes much of the work of using a computer (no bootstrapping, just turn on the power), but leaves much to be desired. Mikbug will load a program from tape, but if you have several programs on the same tape, it loads the first one it encounters. You still have to find the desired program before telling Mikbug to load it. The WA4KDC OS will search a tape for the desired program, loading only the one you've chosen. This is but one feature of the OS. The reason I felt the need for an OS is twofold: First, I happen to believe that a computer should do as much as possible because second, I'm lazy. The WA4KDC OS is not meant to replace Mikbug but to be used along with it.

No listing has been provided with this article. Instead, a dump has been provided. This was done in the hope that Wayne would find room to print it, as a dump takes up less page space than a listing of the same information. Should you desire a listing, the OS itself can provide you with one!

As the OS was written for my system, several assumptions are made:

1. The Mikbug monitor ROM and its associated 128 byte RAM are in place in the system.
2. An SWTPC CT-1024 is used as the control terminal.
3. Tape read and write facilities are available at

*Mikbug is a registered trademark of Motorola, Inc.

the control terminal, and are under software control.

4. An SWTPC PR-40 printer is used for hard copy, and is located at I/O slot #3 (if your PR-40 is at another I/O slot, memory locations 01EF-01F0 will have to be changed to the address of the slot you are using).

As it appears in this article, the WA4KDC OS is assembled to run at 0000-03EB, but it is not really intended to be used there. It was designed to be placed into PROM (along with your favorite version of BASIC) and moved somewhere at the high end of memory, OS 8C00 and BASIC C000-DFFF in my system. All functions except CALL BASIC may be used as it appears here, but the OS will have to be moved higher in memory if the CALL BASIC feature is to be used as will be explained later. The reason the OS is shown here assembled for the low end of memory is because the author has no way of knowing where in memory you will wish to use it, and most people seem to find it easier to relocate a program from the low end of memory.[1]

The WA4KDC OS contains several subroutines for the purpose of outputting data to the PR-40. They are equivalent to subroutines contained in Mikbug and may be called by user programs. They are listed below by address along with the name of the Mikbug subroutines to which they are equivalent.

01C1 – OUT4HS
01C3 – OUT2HS
01C5 – OUTS
01D5 – PDATA1
01EA – OUTEEE

Once you have loaded the OS into memory, set the program counter (A048-A049) to 0073 while in Mikbug; then type "G" to go to the operating system and begin execution. The OS should respond by issuing a "home-up" and "erase to end of frame" on the control terminal, then print the following:

BLOCK MOVE
CALL BASIC
DUMP
LIST
MIKBUG
READ TAPE
WRITE TAPE
ZERO MEMORY ?

The OS will now respond to the following commands: "B", "C", "D", "L", "M", "R", "W", or "Z" (the first letter of each function); typing anything else on the control terminal will cause the OS to repeat the above cycle. Let's examine each function of the OS in a bit of detail.

BLOCK MOVE: Suppose we have a routine located A04A through A060 that we wish to relocate to another area of memory beginning with a starting address of 0200. From the OS main loop, we type B for the BLOCK MOVE function. The OS will then prompt:

MOVE TO ? (we type) 0200
START MOVE ? (we type) A04A
STOP ? (we type) A060

The OS will then move the data, leaving the data in A04A through A060 (in our example) intact, and return to the OS main loop to wait for further commands. The BLOCK MOVE function will move as little as one byte or as much as ½ of the available memory. This function is accomplished very rapidly and irrespective of the amount of data moved; it appears to the operator to instaneously return to the OS main loop!

CALL BASIC: Typing C while in the OS main loop causes BASIC to be automatically block moved from some high location in memory to the low end of memory where it is to be used. (This is the reason the OS cannot be located at the low end of memory if the CALL BASIC function is to be used – it would try to move BASIC on top of itself!) The following addresses should contain the information shown below:

0141-0142 – Address BASIC is to be moved to (as in the "MOVE TO?" of the BLOCK MOVE function)
0147-0148 – Lowest address of BASIC ROM
014D-014E – Highest address of BASIC ROM
0158-0159 – Starting address of BASIC

[1] Relocating the WA4KDC OS is made easy by using the BLOCK MOVE and the LIST functions of the OS to identify those addresses that have to be altered, even though relative addressing has been used extensively.

03F0	00	00	00	00	00	00	00	00	00	00	00	00	00	00	00	00

Upon completion of the CALL BASIC function, system control is given to the BASIC interpreter instead of returning to the OS main loop. This function is also accomplished very quickly with the BASIC prompt seeming to appear as soon as the "C" command is typed – no more waiting for fifteen or twenty minutes for BASIC to load! (Tom Pittman's TINY BASIC and the WA4KDC Operating System will fit into 3K of PROM with room to spare!)

DUMP: Suppose we desire a "Core Dump" beginning with address 1000. Typing D while in the OS main loop will cause the OS to prompt with:

START DUMP ? (we type) 10

The OS will then print (using the PR-40) 128 bytes in standard core dump format beginning at address 1000. After dumping 128 bytes to the PR-40, the OS looks for one of three commands:

B – Dump the next frame back (lower address)
F – Dump the next frame forward (higher address)
S – Stop dump and return control to OS main loop

LIST: The LIST function of the OS, while similar to the DUMP function, uses the following format: address, OP code, operand. Suppose we wish a listing of 01BA through 01BF. Typing L while in the OS main loop will cause the OS to prompt with:

STARTLIST ? (we type) 01BA
STOP ? (we type) 01BF

Assuming that we have the OS in memory locations 0000 through 03EB, the OS should then print (using the PR-40):

```
01BA CE 005B
01BD 8D 16
01BF 20 DF
```

Upon completion of the LIST function, control is returned to the OS main loop. It should be noted that ASCII encoded strings tend to confuse the poor OS. Once beyond the strings, it will usually recover rather rapidly.

READ TAPE: As mentioned earlier, the OS will search for a particular program on tape and load only the desired program (assuming the tape is formatted with a header record for identification – see WRITE TAPE). While in the OS main loop, if an R command is typed, the OS will prompt with:

READ ?

At this point, the OS is requesting the name of the program you desire it to load into memory. After entering the name of the program, type a "Control D" to indicate to the OS that the entry is complete. The OS will then turn on the tape reader and begin searching for the desired program. When it is found, it will be read into memory; everything encountered on the tape before the desired program will be ignored. After the program has been read into memory, system control is given to Mikbug, so typing "G" will run the program.

WRITE TAPE: The WRITE TAPE function of the OS outputs programs to tape in the following format: header, header record, program, program counter starting location, three S9s, trailer. The header, a series of nulls, gives a cassette recorder time to reach normal tape speed before any data is output to tape. The header record (name of program) identifies the program to the READ TAPE function when, at some later time, it is desired to load the program from tape. The three S9s indicate the end of program to the OS when the tape is later read into memory. The trailer, a series of nulls, is added to provide some physical spacing between programs on tape. Let's assume we have Star Trek in memory from 0000 to 1FFF, with an entry point of 0100, and we desire a tape of it. While in the OS main loop, we type the WRITE TAPE command, "W", and the OS prompts with:

WRITE ? (we type) STARTREK "Control D" ("Control D" indicates end of entry to the OS)
START TAPE ? (we type) 0000 (lowest address of program)
STOP ? (we type) 1FFF (highest address of program)
START ? (we type) 0100 (program entry point)

The OS will then turn the recorder on, generate the tape (formatted as described above), turn the recorder off, return control to the OS main loop.

ZERO MEMORY: This function will clear any amount of memory from one byte up to the entire RAM memory in the system; it appears to the operator to perform its task even faster than the BLOCK MOVE function! The first time you use the ZERO MEMORY function, you may wish to go to the Mikbug memory examine function and do some random checking to prove to yourself that the OS actually did clear the memory! To clear the memory used in the Star Trek example above, type a Z (while in the OS main loop, of course). This will cause the OS to prompt with:

START ZERO MEMORY ? (we type) 0000
STOP ? (we type) 1FFF

Upon completion of the ZERO MEMORY function, system control is returned to the OS main loop.

MIKBUG: This function turns system control to the Mikbug control loop. You may, while in Mikbug, return to the WA4KDC OS by typing G.

Although considerable effort has been expended to assure that the WA4KDC Operating System is "bug free," and it has been running on our system for some time with no known bugs, we would be most interested in hearing about any bugs you may find. ■

PROM Message Generator for RTTY

- - keyboards are obsolete!

This article describes what started out to be a simple CW identifier mainly for repeater use. The circuit, however, can easily be changed to send almost any length or type of message. Some possible uses are a CW identifier, Morse code message generator, RTTY test message generator (RYs, the quick brown fox . . .), RTTY message generator, and an automatic telephone dialer.

Three of the basic CW identifier circuits have been built. The first one has been operating in the WR4AKK repeater since Christmas of 1974. The second one was built for WB4CCB, who uses it to identify himself on VHF. And, finally, seven months after the circuit was designed, I built one for myself. I should mention that the first two identifiers were a combination of TTL and CMOS logic. But, because most hams are not yet familiar with the peculiarities of CMOS, I redesigned the circuit using all TTL.

The Memory Unit

For the memory unit, I chose to use a field programmable read only memory or PROM. PROMs are now appearing on the surplus market at prices that the average ham can afford. PROMs are smaller and easier to work with than a diode matrix, are easy to design with, and – believe it or not – most are easy to program.

A PROM can be thought of as a black box that has X number of inputs and Y number of outputs. What goes on inside during operation really doesn't need to concern us at this point. PROMs are sold with all the output stages in the same logic state, either 1 or Ø. Whether the output stages are initially all 1s or Øs depends on the manufacturer. During the programming process, you, the user, decide for a

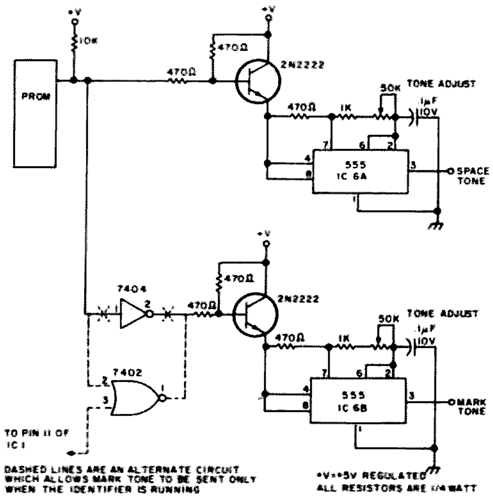

Fig. 3. A modification to the tone generator of Fig. 2 to allow two-tone operation for RTTY use.

specific address what the output states will be and program accordingly. For example, if you want output one to be a Ø for address 3, and the PROM has all outputs initially at Ø, you do not have to program anything into address 3. If, however, you want output one to be a 1, you must apply a programming voltage to the PROM to cause this output to change. (For programming information see the specific manufacturer's spec sheet.) Once an output has been programmed, it cannot be changed. (Some of the newer MOS PROMs can be erased and reprogrammed, but the entire PROM must be erased – not just one word or one bit at a time.)

The input lines to a PROM are called address lines. Each address selects one word. For example, a Ø on all address lines selects word zero. An address is the sum of the binary weights of the address lines. Address line AØ has a binary weight of 1, address line A1 has a binary weight of 2, address line A2 has a binary weight of 4, and so on. Fig. 1 shows a four input PROM and its address table. This PROM has a maximum capability of sixteen words, with addresses zero through fifteen. For every input address there is at least one output stage which is unique to that address. The output stages are tied to each other in groups. That is, if there are four outputs for each address, all of the output one stages (for every address) are tied together, all of the output two stages are tied together, and so on. Even though the output stages for every address are common to each other, only the output stages corresponding to the selected address are active. For example, for a four output PROM every address activates four outputs. These outputs can be any combination of 1s and Øs and are programmed separately.

PROMs are available with three types of output stages: Totem-pole, open collector, and Tri-state (Tri-state is a trademark of National Semiconductor Corp. for their three-state output devices). The Totem-pole output PROM is a new product just released by Harris Semiconductor. It features a standard TTL output stage.

Three-state PROMs have an enable input which, when it is taken high, will force all of the outputs to a very high impedance. This allows several outputs to be bused together. Three-state PROMs also have internal pullup resistors on the output lines. These resistors insure that when an output is high, the output will be close to +Vcc.

Open collector PROMs also have an enable input. When this input is high, all of the outputs are forced off. Open collector PROMs do

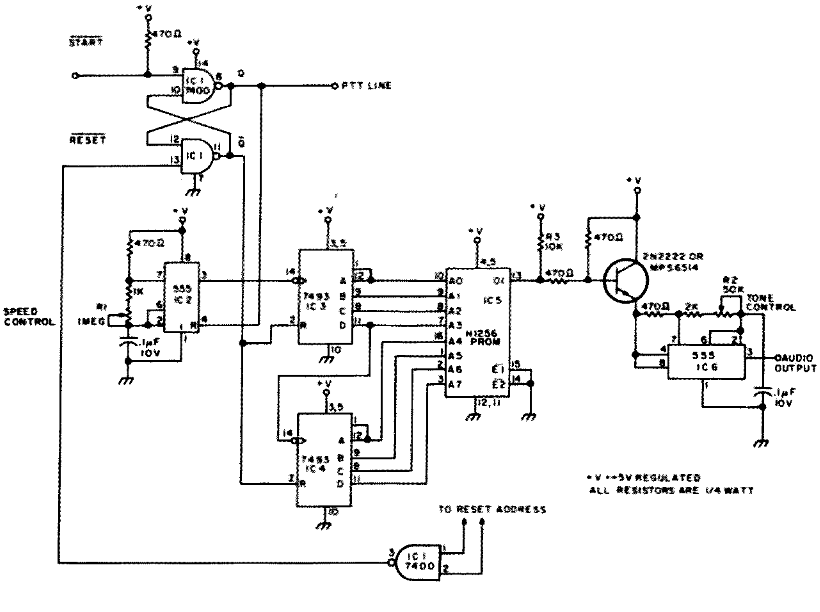

Fig. 2. The basic CW identifier. This circuit features adjustable speed, adjustable tone, and up to 256 bits of memory. The PROM pinout is for a Harris 1256, 256 x 1 PROM.

not have internal pullup resistors. To insure that the output does go to a logic 1 when we want it to, an external pullup resistor must be connected from the output to the +Vcc supply.

A PROM with four inputs and one output is called a 16 word by 1 bit (16 x 1) PROM. If a PROM has eight inputs and four outputs (a common configuration), it is a 256 word by 4 bit (256 x 4) PROM.

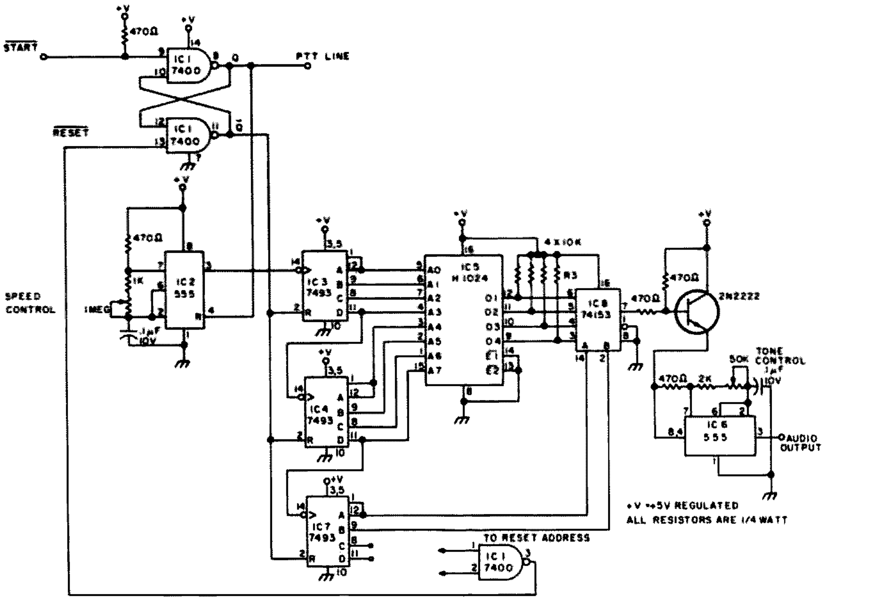

Fig. Ø. An expanded identifier. This circuit features adjustable speed, adjustable tone, and up to 1024 bits of memory. The PROM pinout is for a Harris 1024, 256 x 4 PROM.

Circuit Description

IC1 is a 7400, two gates of which form the ID start flip-flop (Fig. 2). If pin 9 of IC1 is momentarily taken low, pin 8 of IC1 goes and stays high. This high level turns on IC2, a 555 astable multivibrator, which provides the clock signal for driving the counters. At the same time that pin 8 goes high, pin 11 goes low, allowing the two 7493 four bit binary counters to begin counting. IC3, a 7493, counts on the negative transition of the clock. IC3 addresses the PROM from Ø (A0-A7 low), to address 15 (A0-A3 high, A4-A7 low). When the next negative transition of the clock occurs, IC3 changes back to Ø and IC4, another 7493, advances to count 1. This corresponds to address 16 (A4 high, A0-A3 and A5-A7 low). In this manner the PROM is sequentially addressed starting at address Ø and ending at the maximum address of the PROM. In the case of this 256 x 1 PROM, when the counters reach 255, the maximum address has been reached. At clock count 256 the PROM will be back at address Ø. The counters will continue counting and the PROM will be addressed through its entire contents again and again. To stop the counters and reset them at the end of your message, one, two, or three address lines are decoded with a NAND gate to detect the reset address. When all of the inputs to the NAND gate are high, indicating the reset address has been reached, the gate's output goes low, applying a reset pulse to pin 13 of IC1. When pin 13 is taken low, pin 8 of IC1 goes low, stopping the 555 clock, and pin 9 goes high, resetting the 7493 counters. For example, to send my call, WB4EHG, requires 6Ø address locations. Sixty is represented by address lines A2, A3, A4, and A5 being high at the same time. To reset at address 6Ø would require a four input NAND gate. But, if I were to reset at address 64 (A6 high only) instead, I can use one of the unused gates in IC1. For addresses 61, 62, 63 and 64, the PROM output must be Ø. If the output were 1 for these addresses, a tone would be sent by the tone generator. It's a good idea to program a few addresses low after your message, to insure that the message is complete and the tone generator is off before and during reset.

Resistor R3 provides the pullup current to the output stage of the PROM. The use of this resistor was discussed earlier in this article. When the output of the PROM is high, as it is when you wish a tone output, transistor Q1 is turned on, which turns on IC6 by raising its Vcc line from +2.5 V to +5.0 V. IC6 is a 555 astable multivibrator which serves as a tone oscillator. By using Q1 as a keying switch and keying the Vcc line, the oscillator turns on without producing a key click. R2, the 50k Ohm pot, is a tone control. The tone frequency can be varied between 100 Hz and 2.5 kHz.

An external tone oscillator may be used as long as you properly interface it to the PROM output. Most PROMs will drive ten standard TTL loads (16 mA output); but, if you are in doubt, check the manufacturer's specifications.

If you are building a RTTY message generator, the tone generator circuit of Fig. 3 can be used. This circuit has two 555s, one to generate the mark tone and the other to generate the space tone. An inverter is needed between the PROM output and the mark tone generator. The fourth gate of IC1 can be used or you can add another IC.

Code Programming

Now that we know how the addressing is going to take place, let's take a look at what each address is going to do. Morse code is made up of dits and dahs. Each dah is equal in length to three dits. Each address, therefore, will be equal to one dit length. If one lone address has a one programmed in its output, it will turn on the tone oscillator for one clock period, producing a dit. If three addresses in a row are turned on, the tone oscillator will be turned on for three clock periods, producing a dah. The space between dits and dahs of the same letter is equal to the length of one dit. The space between letters of the same word is three dits (one dah), and the space between words is six dits (two dahs). For example, to store a W in memory takes nine addresses (Table 1). Since address zero is on and address one is off, the tone oscillator will be on for one clock period and off for one clock pulse, thus forming a dit. Addresses two, three, and four are on and address five is off, so the tone oscillator will be on for three clock periods and off for one, thus forming a dah. Table 2 shows the address locations to send CQ DE.

I would suggest that you program the first five or so addresses as zeros. This will give a slight delay from the time the generator is started until the code starts rolling out. In a repeater, this delay

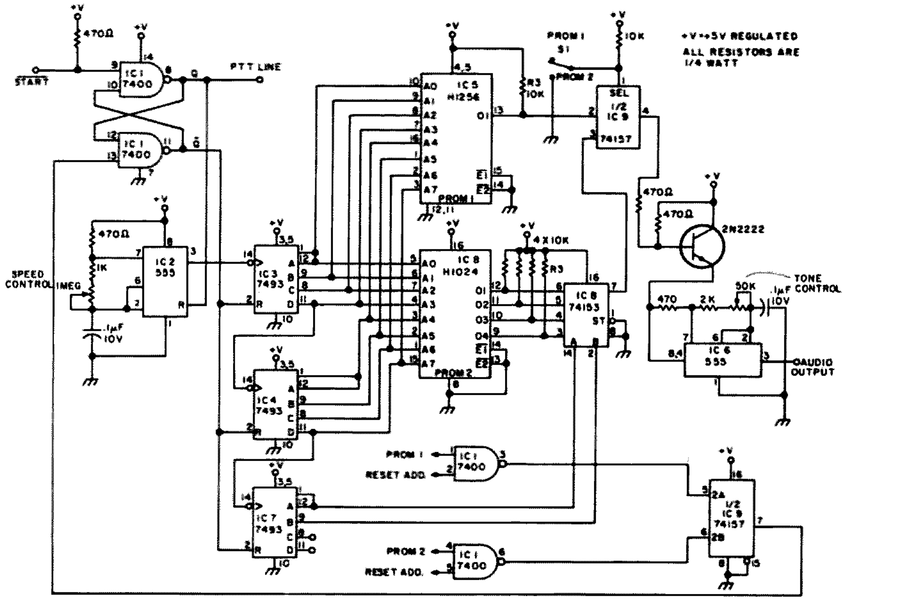

Fig. 5. A combination of Fig. 2 and Fig. 4. This circuit features adjustable speed, adjustable tone, and selection of two PROMs. Switch S1 selects PROM 1 or PROM 2. Each PROM has a separate reset address. The PROM pinout for PROM 1 is a Harris 1256. PROM 2 is a Harris 1024. I use PROM 1 to send my call and PROM 2 to send my name and address.

will give the transmitter time to come up, eliminating the possibility of chopping off the first part of the first letter sent. This is a matter of personal choice. If you do not want a delay or have a very long message to send, start your first letter at address one. Address zero must have a zero programmed in it. This address is selected when the identifier is in the reset condition and a one here will cause the tone oscillator to be on constantly. If you use this circuit as a RTTY generator, this will cause a mark tone to be sent while the generator is in the reset mode. If you do not want the mark tone sent during reset, use the alternate circuit of Fig. 3.

Selecting a PROM

Of all the PROMs on the surplus market, the 32 x 8 is probably the most common. This PROM is good for use as an automatic telephone dialer, but as a simple CW ID generator it requires too much extra circuitry (although an adaptation of Fig. 4 could be used). A 256 x 1 PROM is more than enough for sending your call and QTH. If you have a long message or several different messages to send, a 256 x 4 or 512 x 4 can be used. A 256 x 4 has a total of 1024 bits of memory and a 512 x 4 has 2048 bits. A 256 x 4 is large enough to send my name, full address, and even the name of the company I work for.

If you obtain a PROM with more memory than you need, you don't have to program all the memory at one sitting. You might, at a later date, want to send something different and, by changing your counter circuit, or by using a different output of a multiple output PROM, you can program the unused addresses.

Expanding the Basic PROM Generator

Fig. 4 shows a modified Fig. 2. The circuit has been modified to use a larger PROM (more outputs). The start, clock, and tone generator circuits are identical to the basic generator circuit. Now, however, instead of using a single output PROM, I am using a four output PROM. The 7493 binary counters count and address the PROM as before, but a new counter has been added so that when clock count 256 occurs, the PROM address is back at zero and pin 12 of IC7 goes high, causing the second output of the PROM to be connected to the tone generator through IC8. IC8, a 74153, can be thought of as a four position electronic rotary switch; the position of the switch is selected by IC7. On clock count 512, the PROM address is back at zero again and output three is tied to the tone generator. Likewise at address 768; output four is tied to the tone generator and the PROM is at address zero again. This scheme allows sending 1024 bits of data in an unbroken stream. Resetting is done as before by decoding the reset address line with a NAND gate and taking the reset line of the start flip-flop low.

RTTY Message Generator

To build a RTTY message generator you can use either the circuit of Fig. 2 or that of Fig. 4. Every RTTY character consists of seven parts: a 22 ms start pulse, five 22 ms data pulses, and a 31 ms stop pulse. The total time for a 60 wpm RTTY character is the sum of these pulses, which is 163 ms. By adjusting the period of IC2 to 11 ms and letting two addresses represent the stop pulse, a RTTY character can be sent in 165 ms. Because with this timing the stop pulse is 2 ms longer than normal, the generator will be sending at about 1% slower than 60 wpm. I doubt that you will be able to see any difference. The longer stop pulse does not affect the TTY timing because if no character is sent, the machine

Address	Output state	Represents:
0	1	space tone (start)

13	0	mark tone (stop)
14	0	mark tone (stop)

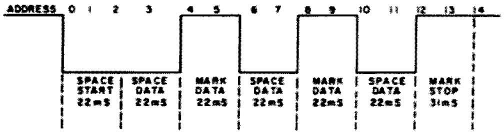

Table 3. Address locations and memory content to send the RTTY character R. Note that each RTTY character requires fifteen addresses.

Configuration	Bits	Maximum no. of RTTY characters
32 x 8	256	17
256 x 1	256	17
64 x 8	512	34
256 x 4	1024	68
512 x 4	2048	136
512 x 8	4096	273

Fig. 4. An expanded identifier. This circuit features adjustable speed, adjustable tone, and up to 1024 bits of memory. The PROM pinout is for a Harris 1024, 256 x 4 PROM.

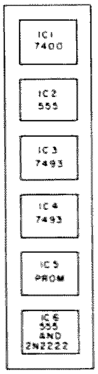
sees a constant stop signal. Either the two-tone generator of Fig. 3 can be used or you can use your own AFSK oscillator. Table 3 gives a programming truth table for sending a RTTY R. As you will notice, because every RTTY character is of the same fixed length, it will take fifteen addresses to send a RTTY character. There is no need for spacing between characters due to the existing start and stop pulses. Table 4 shows the maximum number of characters you can store in some of the available PROMs.

Construction

The layout and wiring for these circuits is not critical. All voltage lines should be bypassed where the lines enter the board and at several points on the board, directly at the Vcc pins of the ICs. If you plan on using this circuit as a repeater identifier, shielding the whole circuit board may be necessary to keep rf from triggering the circuit or causing the counters to count extra counts.

I have built one of the identifiers using wire wrap and two using circuit stick. I would suggest that unless you like the messy job of making printed circuit boards, you use circuit stick. Circuit stick is adhesive-backed copper patterns that are used with predrilled boards. Patterns are available for all kinds of circuit elements. I also suggest that you use sockets for the ICs. The extra cost of the IC socket will be forgiven the first time you have to unsolder a soldered-in IC. Fig. 5 shows the layout I used for the two circuit stick boards. Wire wrap is great if you can afford the cost of the wrap gun and wire wrap board. For the ham interested in only an occasional circuit board, I don't suggest you invest in a wire wrap outfit.

Fig. 6. This is the layout of the circuit in Fig. 2 when using circuit stick.



Conclusion

The most obvious use for this circuit is as a repeater identifier. But because of the versatility of the PROM, this circuit can have hundreds of uses. Some examples are:

For the repeater — automatically dialing police and fire phone numbers in following with the 911 plan; automatically bringing up the repeater and sending an alert message in the case of someone breaking into the repeater site.

For the ham shack — an automatic station identifier; automatic CQ caller; automatically send QSL information; touchtone frequently dialed telephone numbers.

For the RTTY station — all of the above plus as an RY generator, the quick brown fox generator, and to store RTTY pictures. ■

FCC-Approved Microprocessor

-- use it for the code test

Would you believe that you can build your own portable semi-solid state minicomputer, take it to an FCC examination, and use it with the inspector's blessing? You may think there is some catch to this, but your curiosity is aroused. Or perhaps you think, "Code's a cinch, so who needs it?" Well, let's just listen up here around 50.4 MHz for a minute.

> "Yeah, Al, I went down to the candy company a couple of times to try for the General, but I finally decided that this class of license is nothing to be ashamed of. We got it pretty good here on six meters. It's not crowded. In fact, the band really needs the activity. We're performing a public service, the way I look at it. Anyway, cee-dubble-yew isn't really like talking to somebody. The low bands are way too crowded now with all those sidewinders squawking away on top of each other down there. Yes sir, six is the only band where you can still have a good old-fashioned QSO any more."

Now let's read the mail on the repeaters. Sounds like the gang on 16/76 is heatedly discussing mobile rig rip-offs. Gee, what happened? Bill just asked Stan if he had worked any of that hot DX on twenty meters last night and nearly everyone destinated or got a land line all of a sudden. Aw, come on, why would they be embarrassed?

OK, I admit it. I was one of those dudes until about a year ago when I rediscovered *73 Magazine*. Wow, there was a bright new world out there! Wayne Green had built a bridge which made international Morse code at 13 wpm attainable. I could stop pretending I was as real a ham as those others. That inspired the experiments which led to Codebuster. You can build a similar system, and there's no reason why it can't take you on to 20 wpm and the Biggie if that's what you really want. I wasn't kidding about Codebuster. This is actually a construction article, so let's get started.

A black box of any convenient size will be appropriate for housing the unit. Just think of it — that black box with its sophisticated microcircuitry smoothly converting audio input into video and graphic output. When properly programmed, the speed of translation is limited only by the physical response time of the graphics drive. Now that wasn't hard, was it?

Nikola Tesla, it is told, designed his ac motors and generators by carefully assembling scale models in his mind. When they were later built, the real prototypes were found to perform in every respect as Tesla had imagined they would. Even the patterns of wear on the moving parts had been predicted.

It is apparent that each of us has a built-in bioelectronic microprocessor of fabulous capability. Each second it performs routinely feats of information processing and retrieval unequalled by the largest solid state machines. Some of its input channels haven't even been identified yet. What we've done is to dedicate one tiny partition of it to serve temporarily as our black box. Building Codebuster is a snap. Now all we have to do is program it properly.

Operating as designed in its normal state, our master computer should be as capable as any physical device of executing flawlessly and instantaneously any desired function. We simply feed in a lookup table of sound equivalents for the various characters and we're in business. Dit dah is A, dah dit dit is B, and so forth. Did I hear you say that it isn't that simple?

All right, why not? There are two reasons, basically. One is scattered attention. The input data gets mixed with so many thousands of bits of other data each second that our computer gets confused. The other reason is the existence of many levels of previous programming, much

of it contradictory. This is called conditioning, and unfortunately most of the documentation for it is not readily available. That makes debugging something of a challenge at times. But despite all this, it's not difficult to prove that the inherent functional capability is there.

Experimentally, normal subjects like you and I have been asked to watch a passenger train as it roars through a suburban station in a featureless blur of motion. Later when their minds were properly relaxed, they could recall in complete detail what was seen in each window of the passing train. Features of the passengers, their hair and clothing, could all be accurately described. Verification was provided by comparison with slow motion movies or independent accounts of other observers. Explain this however you will, our minds can be shown to possess fantastic capability when allowed to perform as designed. Obviously there's no problem with the computer itself. It is the programming and output that will make our Codebuster function properly.

Although we began a small debugging operation earlier in the article, it will be necessary to go much farther. Let's have a look at that old program. Who told you that code was hard? When did you decide that you'd never be able to copy 13 (or 20) words per minute? How many times can you remember saying, "I hate code"? Are these attitudes of any help to you now? Perhaps the time has come to put that old program out to pasture and replace it with a new one.

Code is very much alive. Most resistance to it appears to stem simply from unfamiliarity with it. You could begin to think about its advantages and usefulness. Thumb through a copy of the Callbook some time. It is fat with the names of thousands of hams throughout the world who have used and enjoyed CW. Listen to CW on the ham bands or commercial transmissions on a general coverage receiver. Nobody makes any of those people use that mode of communication. So whether you intend to use code or not, deliberately reprogram your attitude toward it. And know, deeply and *firmly*, that what hundreds of thousands of others have done, you can do – and will!

Any successful endeavor requires first of all a clearly defined goal. We need to visualize exactly what we want to accomplish. And secondly, we must generate and maintain a strong desire to reach that goal. We can't just pretend that we want to learn code. If hangups or attitudes of self-depreciation stand in the way, we want to recognize and change them. There are new methods, new tools, new FCC examinations, and we need a positive and confident attitude to go with them. You want to be able to send and receive 13 or 20 words per minute so bad that you can taste it. Good, that's the operating system for the Codebuster. Keep it that way.

If you have ever had any kind of amateur license, you were able to send and receive at least 5 words per minute. That may be an asset. But you could have learned code at that speed by sight. Those little tables of letters followed by dots and dashes are murder. If you never studied one, thank your lucky stars. We want to establish an automatic motor response to an audio signal – not translate the sound for each character through some visual delay circuit. A is simply the sound dit dah, nothing more. Hear it, write it. This way we place no artificial limitation on the speed of comprehension and your Codebuster will function as it should from the beginning.

Many years ago, an old-time railroad telegrapher confided to me the secret of his expertise. "It's easy," he said. "I just read a stream of beautiful purple characters which passes across my mind's eye like a tape." He had created a Codebuster in his mind and it did all the work for him. He programmed his computer creatively in a way that was efficient and esthetically pleasing to him. Now purple letters may not appeal to you. You may prefer direct graphic output via the old pencil. But you may find that some form of visualization helps you to concentrate, at least in the beginning. So experiment with it if you like.

Since you're going to be copying code at 13 wpm, it makes sense to use instructional material in which components of the characters are spaced at that speed. This avoids having to relearn the code at each successively higher speed. It is a good idea to review from the beginning anyway, since most people have neglected numbers and punctuation. For this reason, an investment in the *73* code tapes, including the 5 wpm learning tape, is very worthwhile. If you think that this new system is only Wayne Green's advertising gimmick, perish the thought. It's the biggest advance in learning code since Morse invented it. It even worked for me!

Have you considered the optimum form of output for your Codebuster? Please, seriously consider writing the characters. Printing is quite difficult for most people at 13 wpm and next to impossible at 20. On the other hand, ordinary handwriting is smooth and easy even at 25 wpm. You will never regret learning to write code and the FCC could care less. They won't even read your copy under the new system. So why place an unnecessary limitation on the graphic response time of your machine?

The first sessions will be fun. In a relaxed way, build your mental table of sound equivalents and write the characters as you listen to them. Soon you'll move on to the 6 wpm tape and be copying code groups, at least some of them, pretty well. But code groups don't seem to be much fun. Thirteen wpm still sounds like white noise to you – all you can make out is a period now and then. And you just heard Joe calling QRZ on the repeater. Hold on there – the voltage on your ICs is dropping. We'd better check the power supply.

You know that it takes voltage and current flowing in a circuit to produce power. If our resistance is too high, nothing can be accomplished. So whenever we detect resistance rising, we must increase the voltage and reduce the resistance. We need, in other words, both a clearly defined goal and a powerful incentive to reach it. Remembering these principles can save us a lot of sweat and tears. The primary challenge for most people studying code, aside from arranging regular study periods, seems to lie in this area. You can grit your teeth, get out the old horsewhip and do it the hard way, or you can do it the easy way and enjoy it.

Code study will become a habit in a surprisingly short time if you make a regular time for it each day. Many people find it convenient right after the evening code practice transmission of W1AW. Practice less often than every other day may make the road a long one for you. Once you begin to copy smoothly at any speed, you should find the period pleasant in that it mobilizes enough attention to relax your mind. But to get back to that power supply, let's consider some ways that you can crank up your voltage and decrease your resistance.

Why not arrange some activities that you enjoy to serve as rewards? Listen to some SSB on the low bands, for instance, and frankly admit to yourself how much you would like to talk to

those hams. Thumb through the ads in *73* and drool over some new gear. Picture your dream shack in your mind. You're sitting there working a beautiful YL (or a handsome OM, if you are a YL) in some exotic QTH halfway around the world – or maybe in the next town. "U HAVE A NICE FIST BUT PSE QRS," you copy. Don't laugh. You've got to psych yourself up a little. After all, if you don't, who will? So invent some incentives.

One ham who finally made General after a real struggle at an age when most people wouldn't have tried is fond of telling newcomers, "If you want that ticket bad enough, you'll get it!" Well put, Mac. Wanting it badly enough is indeed the secret. So want it. Want it so bad you can taste it. And keep on wanting it while you prepare to get it. Isn't that easier than a negative, half-hearted approach which may get lost in the QRM halfway through the schedule? Start saving for that low band rig. Plan the antennas you'll put up. Dream a little – or a lot – but engineer it to stimulate rather than distract from your code practice.

OK, we've gotten over the first barrier and have progressed right along. Straight text at a challenging speed has been alternated with code groups and reversed text. You can copy most of what you hear in the Novice bands, and isn't it swell that the Techs can finally get in there and increase their code speed with on-the-air practice? Or can they?

Let's be honest with ourselves now. Increasing proficiency requires challenge. Do you deliberately work someone who is too fast for you, or are you embarrassed to ask for repeats? "SORRY, BAD QRM OM, 73." And consider the format of a typical Novice QSO. Everything but the handle and address identical each time, and those are sent three times at about four words per minute. You could work stations that are comfortable for you to copy for years without increasing your speed at all. So it will take regular schedules with practice material being sent at higher speeds and regular sessions with your tapes to do the job. It's great that you enjoy CW QSOs, but use them as a reward after a solid study session instead of a delusion.

Now you're copying 10 solid, and 80% or so at 13 wpm. But in the last two weeks it doesn't seem that you've made much progress. In fact, some nights you are actually worse, and you're getting discouraged. Is it that dreaded plateau you've heard about? Don't worry. That used to happen with the old methods of studying code when it had to be relearned at each higher speed. But characters built with 13 wpm spacing circumvent this difficulty. Let's keep up the incentives while we troubleshoot the problem.

Is your practice challenging but not exhausting? Do you always follow it with some pleasant activity as a reward? It might precede your nightly QSO with John on six meters, or a TV program you are fond of watching. Or maybe it's that cold 807 and a bedtime snack that you look forward to. This kind of human engineering will help you over the rough spots. Don't force practice to the point where you build up more resistance than you can handle. Analyze the problem. You're only going to have to copy five minutes of code for the test. The length of time you can copy without strain will increase along with your proficiency. Stop and relax whenever you feel yourself tensing up. Take some deep breaths. Try to keep it pleasant.

Your progress may not be even. With most people it's not. There are some procedures you can try if it seems slow. Listen to very fast code as though it were music, code at a speed much faster than you can begin to copy. Pretty soon you will start to recognize a character here and there. Some people begin each session with a few minutes of fast code even though they can copy only 20 or 30% of it. Then when actual practice is started, it sounds very slow and leisurely by contrast.

Think code whenever you can, at least several times a day. Read license plates or street signs into code while driving to the salt mine in the morning. What would the menu sound like in code at lunch? Relate code to things you do each day so that it becomes part of your life rather than some minor extraneous activity. And visualize yourself, particularly just before you go to sleep, easily and enjoyably copying code at your desired speed. This need take only a few seconds, but it does a great job of programming Codebuster at a subconscious level.

Now we are ready to make the final push, to surmount the last barrier. To do this, we will employ fast code as a diagnostic tool. A warning here – this will cause you to memorize and render worthless as practice material whatever you use. Therefore work with only a short portion of your code group tape at 14 wpm, or better yet some other similar material. Do the best you can to copy it. Then listen to this section over again as many times as necessary to correct your errors of omission and commission, noting each one. You'll probably find, as I did, that only a few characters are giving you all the trouble. When you hit one of these and aren't certain of it, you hesitate to think about it and then skip several succeeding characters. Once these troublemakers are identified, you can work on them specifically. In a short time, you'll be copying code consistently at a much higher speed.

Each person has some individual hangups on certain characters. I had difficulty telling B from D and H from S. Many people find 7 and 8 confusing, or 2 and 3. Characters such as Z or Y are less often used in straight text, so they are practiced less. Code groups which use each character with the same frequency overcome this liability. Once you have identified your particular stumbling blocks, spend about half of your practice time working exclusively on them.

Now don't tell me you can't stand to listen to your own sending. After all, other people will have to listen to it, including the examiner. You know that speech is improved by feedback in sales training and speech therapy. The same method will improve your code sending. You will need a chance to listen carefully to these particular characters and analyze them so that you can tell them apart. The only way to do this is to break out your key and record them on tape. Begin at a speed which you can ordinarily copy. Since these characters are probably the same ones you were having trouble sending, you'll bag two birds with the same stone.

If it is H and S which you find confusing, send H H H H S S S S. Repeat each character you find difficult several times to afford ample opportunity to study it, and group confusing characters together. Copy this tape for several days, until you are thoroughly bored with it. Then mix all these characters up on a new tape at a slightly higher speed. Work on this one until you have them all down pat. Increase the speed again, adding other characters that might be similar to them. Construct code groups in which at least half of the characters consist of those still giving you trouble. You can repeat the diagnostic process to identify these as necessary.

As you send and listen to them, note the relationship between the characters in the following groups:

A R L AS AR
N D X /
S V 3 SK
A U V 4
M G Q,
T M O 8
H 4
A W P
T N D B 6 -
E I S H 5
N K Y
G Z 7,
A W J 1
P X Y Q
I U F / 2
,?
N K C.
R L U F

Using this approach, analyzing your hangups and making specific study tapes to overcome them, your improvement will be fast and continuous. If you are working with a buddy, so much the better. You can send each other this type of material.

By now you copy all characters equally well and your code speed is really up there, but the problem is consistency. You can copy half a minute or so perfectly but then something happens and you miss several words. Or you can find yourself writing *modulator* when the word being sent turns out to be *modulation*. The name of this game is anticipation, and it can be a problem indeed. The mind tries to avoid effort by guessing from the context what is coming next. When that turns out to be wrong, confusion results and characters are missed until the copy can be picked up again. Trying to correct the missed copy only makes things worse. You are reading the message instead of copying the code. Your job is to disconnect the analytical process temporarily and let your Codebuster produce copy automatically.

During World War II, Algerians were trained to copy code in English although they did not understand the language. This is the process which must occur in your mind initially. Comprehension while receiving will develop later on as the process becomes an automatic response. It is like being able to talk to someone while driving a car. At this point, comprehension is not the objective. You can always read your copy later. Since anticipation is a serious liability with straight text, work with code groups or reversed text to overcome it.

If you are able to receive W1AW, their daily code transmission can furnish you with good practice if a few lids stay off the frequency. All too occasionally they send text in which the order of the words is reversed. This is far superior to straight text for practice and easier to take than code groups. Tapes of such material can be used several times, in contrast to straight text. So if you can, get someone to send you reversed text. Make your own tapes if you have to. But stay away from copying straight text until you have whipped anticipating.

Since anticipation is a process of thought, we can devise methods to prevent it. Some people find it helpful to keep their attention focused on a blank screen in their mind. When a letter is completed, it appears there and they copy it. Or you might try to become aware of the stimulus-response process as it occurs. Instead of focusing your eyes on your copy, direct your attention internally to Codebuster wherever you feel it is located. With your eyes unfocused you can still write a straight line on the paper, but can't read it. Like the operators in Algeria, you are not concerned with its meaning at that time. You hear it and you write it.

Learn to maintain an intense state of detached curiosity about the next character you are going to hear. Be willing for it to be whatever it will be. Simply let it be written effortlessly and instantaneously as soon as it is complete. No thoughts distract your attention. If you miss a character, just let it pass and wait placidly for the next one. You are, for the moment, The Codebuster, efficiently transforming audio signals into graphic output. Once you get the hang of this, believe it or not you will actually enjoy copying code. Then as your proficiency increases and the process becomes fully automatic, you will find yourself understanding what you are receiving without anticipating it.

At this point you've almost got it made. Straight copy at 15 wpm is a breeze and you're ready for the code test. Or are you? Let's not kid ourselves at this stage of the game. In the first place, the FCC will not send you cream-puff straight text like you get from W1AW. And you won't be in your quiet familiar room. You'll be in a large, strange room listening to a tone higher or lower than you prefer from a speaker at some distance from you, probably a little nervous and surrounded by other people. Have you given yourself any practice under such conditions? Your actual code speed is not what you can copy with easy material occasionally under ideal conditions. It is what you can copy with difficult material consistently under somewhat adverse conditions. So take your recorder with you on trips and practice in a motel. Copy code at work during your lunch break. Vary the BFO note frequently. Turn on the TV or radio in the background. Check your speed when you're tired or upset, and with other people around. You will know whether you're ready or not.

Many people have fallen into the trap of having memorized their practice material. You may have recorded a large collection of tapes and used them only infrequently, but your computer never forgets. At a subconscious level you are familiar with material you have only heard once. Don't fool yourself into thinking that you are better than you are. You are just as good as you can copy new, unfamiliar material. Even reversed text becomes familiar after several hearings, so don't neglect the code groups. They are your insurance and the ultimate test of your ability.

Make sure you can copy material sent at several speeds. A number of people who could copy 15 or even 18 wpm solidly were unpleasantly surprised to find that they were very inconsistent at 13 wpm. The less challenging slower speed gave their minds time to anticipate. So while the fastest progress seems to be made practicing with material at a speed high enough to be quite challenging but not discouraging, it is a good idea to spend part of your time working at the speed at which you will be examined.

So it's back to the code groups for the last push. When you can copy that 14 wpm tape consistently under less than ideal conditions, then you are really ready, and not before. Of course, the experience of taking the code test can be valuable if your location is convenient. You're not even out $4 now if you don't make it. On the other hand, it can be discouraging to fail in public. You know your own reactions and will have to weigh the pros and cons for yourself.

Speaking of examinations, how do you feel about that? If just thinking about it makes you apprehensive, you need some practice. The next time you prepare to copy 5 minutes at 13 wpm, imagine yourself taking the FCC exam. Feel how important it is that you pass. Although you have been programming yourself to copy code in a relaxed manner, an occasional session which is deliberately mocked up in this way will prevent nervousness on the big day. Others around you will be nervous and that can be catching. So practice "taking the code test." Get someone else to time you. And when you no longer feel tense in this situation, you

will be cool, calm and collected during the real examination.

With comprehension testing for code receiving proficiency scheduled to be adopted by the FCC in 1977, your goal should be somewhat closer. Although designed to permit rapid grading of code tests by machine or template, the new examination will be easier on applicants who miss an occasional letter. No more will 65 successive error-free characters be the criterion for passing, but 16 out of 20 correct answers to TRUE/FALSE questions based upon the material sent in five minutes. Numbers, of course, will continue to be crucial.

What can you expect when you take the new code test? In the past, a disaster or accident of some type has often been the subject, liberally sprinkled with figures such as latitude and longitude, dates and times. Descriptions of equipment and distances might appear. The story may be interrupted with Q signals or an abrupt change in subject, as though a transmission were suddenly subject to QSB or QRM. You can assume that you will encounter the question mark and slant bar as well as the usual periods and commas.

You will be allowed to copy five minutes of code at the speed being tested and can then refer to your paper to answer the true or false questions which will subsequently be distributed. The usual practice of sending one minute of code for tone and volume adjustment can be used for warmup. You may be able to deduce a word even though some characters are missed, but copying numbers wrong will be more serious. Expect the questions to be paraphrased from the text. An example? Supposing you copy, "The transmitter is located 29 feet from the antenna." A question might be, "The antenna is located 28 feet from the transmitter." You would mark the answer FALSE.

Knowing what to expect will foster a calm and confident attitude conducive to good performance. But there's one last bit of programming that remains to be done. The Examiner! How do you visualize this individual? Is your mental image that of a terrible ogre, all-powerful, breathing fire while laser beams shoot from his eyes, gleefully chortling as he fails one hapless applicant after another?

Let's do something about this right now. Of course you can expect the examiner to be efficient and unbiased, but altogether human. He'll probably be courteous and hopeful that everyone is prepared to pass. Consider that he is there to help you, to make it possible for you to achieve that goal of a higher class of license. And it is your taxes that pay for it all. The image of the steely-eyed government inspector may sell Wayne's 14 wpm tape, but it won't do much for your sweaty palms. So expect to see a human being just doing his job, and that's what you will find. And when it's all over, he may even seem like a pretty nice guy. Mine was. After he said, "Congratulations, you've passed," I told him that he didn't look very steely-eyed. He smiled and said, "We're trying to change our image."

By communicating those techniques which have proven most helpful to some people, it is hoped that the path may be made a bit smoother for others. Certainly no special expertise is pretended. Each individual must find through experiment what works best for him or her in building their Codebuster.

To those fellow hams who shared, knowingly and unknowingly, their travails and triumphs, I express sincere thanks. And to those readers who are inspired to challenge the paper tiger whose name is Thirteen, good luck and Godcodespeed. See you on the low bands. ■

LETTERS

from page 61

"THANK YOU"

I have seen many letters in *73* which mentioned the number and quality of construction projects. The writers, however, fail to mention how much of the material for those projects is available from *73* advertisers. In the Holiday issue, I counted 17 suppliers of components for "home brew" projects. This does not include kits and parts of systems (Robot, Seals, Paia for instance). I believe this is more than the other 3 magazines combined (I get all 4 ham magazines, but have not counted).

Another big plus is the arrangement of the advertising. It *is* something of interest to the average reader, and so you distribute it among the articles. In turning from one article to another, it is easy to stop and see just what this ad is about. When advertisers are pushed to the back (the usual place), very few people will bother to look them up.

One policy you have which merits a big "thank you" is that of putting all of each article together. This probably helps more with construction articles than it would (for instance) with fiction, as the reader will find more need for referring to "the first paragraph" or "Fig. 1."

At times I do not agree with your editorial opinion, but at least you do express it. I doubt whether you would agree with me.

One more little thing I would like to mention. CB operators have been cussed and discussed a lot. I wonder how many hams ever stop to think — the CBers do the same thing we do. They get on the air and follow the example of others.

Thanks for letting me unburden myself.

Lester W. Ulch WB4HPB
Birmingham AL

WHAT HAPPENED?

One comment, if you please. Early in November was the ARRL Hudson Division Convention. I didn't go (I can't afford that kind of hamfest); however, I heard that it cost $4.00 to get into the flea market! The buyers paid the $4.00 (I have no idea what the sellers paid; I hate to think of it). Personally, I don't think *any* hamfest is worth paying $4.00 to get into. Maybe that's one reason so many people are going CB instead of ham. Who wants to pay that much for a get-together when they get into CB fests free? (I understand hamfests used to be that way — what happened?)

Bob Billson WA2TXY
Westfield NJ

P.S. I sent a similar letter to *QST*. I'm curious to see if they'll print it — hi!

Hey, Bob, it's a nonprofit organization, right? — Ed.

MILWAUKEE WINTER

In your Holiday, 1976 issue is an article by Scott Smith, entitled, "S22 for a Regulator? Never." Probably by now his car has failed to start in the Milwaukee winter.

First, he mentions that the alternator should put out 13.6 to 13.8 volts. This would hardly allow enough charge for summer, let alone winter. Typical voltages, these for a 240Z, range from 14.25 at 104 degrees to 15.00 at 14 degrees Fahrenheit. This brings up a second consideration — temperature corrections. As zeners have positive temperature coefficients, Scott's regulator will reduce voltage with lowering temperatures.

So far as the circuit goes, *neither* transistor is operating as a switch as the author says (*try* that with an emitter follower sometime). Also, the field can never get full voltage as needed for low speed charging. An average field is about 4 Ohms, an average 2N3055 has a gain of about 40, yielding a field voltage of about 8 volts *maximum*! Commercial solid state regulators use PNP pass transistors, which can be put into a saturating configuration.

Lexington KY

MA BELL — AGAIN

I had one heck of a noise burst forth on the low end of 160. It sounded like LORAN, but didn't synchronize with any of the local LORAN transmitters on either 2 MHz or 100 kHz. It was a 60 cycle buzz, changing now and then to 120 cycles.

I tried to find it, without success, on the power lines; finally had it reappear when I approached the telephone lines. Using a hand-held broadcast radio, it showed a fairly large standing wave on the phone lines. Investigation with a wideband receiver showed its fundamental frequency to be about 900 kHz. No trace on 450 kHz.

I went to the nearest telephone

How Counter ICs Work

-- the next step is a micro

William Browning WB5IRY
516 N. 95th E. Ave.
Tulsa OK 74115

In the past 2 to 3 years, projects that have been coming out of ham shacks across the nation have undergone some dramatic changes.

One of the reasons for this is that integrated circuits of increasing complexity have become available at a price that makes it practical for more and more amateurs and experimenters to build with them. And when amateurs start to build, fascinating things can happen: digital clocks, frequency counters, frequency synthesizers, microcomputers and much, much more.

One of the ICs that is used in many of these projects is the counter chip. It is the counter chip that I am going to be looking at in this article and you will see that it can do more than just count.

Let's start by going into one of the more popular counters, the 7490. This IC is made up of four flip-flops which are internally connected in such a way that the IC can divide by 2 or divide by 5 and, by making an external connection, can divide by 10, or count pulse inputs and give a BCD coded output.

The flip-flops also have a clear and preset which are connected through 2 input NAND gates. The clear and preset are called Reset "0" and Reset "9", as they put the counter in the BCD output condition of "count 0" or "count 9" respectively.

A diagram and pinout of the 7490 are shown in Fig. 1.

To use the 7490 in divide-by-two operation, put the input on the "A" input (pin 14) and take the divided output off the "A" output (pin 12).

To use the IC in divide-by-five operation, put the input on the "BD" input (pin 1) and take the divided output off the "D" output (pin 11).

Notice that the two divide operations are separate inside the IC, so the 7490 can be used as a divide-by-two and as a divide-by-five section at the same time, using a common clear and preset.

For the divide-by-ten operation, both of the divide sections are used. First the signal is divided by five, then fed into the divide-by-two section. To connect the IC for this, connect the "D" output to the "A" input. Input pulses applied to the "BD" input (pin 1) will appear divided by ten at the "A" output (pin 12).

Count	Output D	C	B	A
0	0	0	0	0
1	0	0	0	1
2	0	0	1	0
3	0	0	1	1
4	0	1	0	0
5	0	1	0	1
6	0	1	1	0
7	0	1	1	1
8	1	0	0	0
9	1	0	0	1

Fig. 2. BCD output count sequence.

To use the 7490 in its normal mode of operation as a decade counter with BCD output, the "A" output (pin 12) is connected to the "BD" input (pin 1). The pulses to be counted are applied to the "A" input (pin 14) and the output count will appear as BCD code on the "A", "B", "C", and "D" outputs (pins 12, 9, 8, and 11).

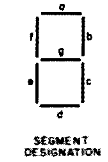

Fig. 6. 7446 truth table.

The BCD output count sequence is shown in Fig. 2.

In some circuits we may be able to use the output as is. That is, in the BCD format. In other circuits, we may need to decode the BCD to decimal form. This may be done with a decoder such as the 7445 decoder/driver which will take the BCD code as it is input and give an output in a decimal form.

A pinout of the 7445 and its truth table are shown in Figs. 3 and 4.

In other circuits, a seven-segment code may be needed to operate one of the seven-segment displays. A decoder such as the 7446 or 7447 BCD to seven-segment decoder/driver may be used.

A pinout of the 7446 and its truth table are shown in Figs. 5 and 6.

In most circuits using the 7490, it will be necessary to reset the counter to either "9" or "0" at certain times. To reset to the BCD count of zero, both reset "0" inputs must be at logic "1", while at least one of the reset "9" inputs is at logic "0". To reset to the BCD count of nine, both of the reset "9" inputs must be at logic "1", while at least one of the reset "0" inputs is at logic "0".

For proper counting, at least one of the reset "0" inputs and at least one of the reset "9" inputs must be at logic "0". Counting of the 7490 will occur on the negative-going edge of the input pulse. That is when the pulse goes from high to low. See Fig. 7.

Fig. 7.

A second counter IC is the 7492 divide-by-12 counter. It is similar to the 7490, but the second section is connected internally to divide by six and there is no reset to "9", only a reset to "0".

A diagram and pinout of the 7492 are shown in Fig. 8.

With no external connections, an input at "A" (pin 14) will give an output divided by two at the "A" output (pin 12). An input at the BC input (pin 1) will give an output divided by six at the "D" output (pin 8) or divided by three at the "C" output (pin 9).

For the divide-by-twelve operation, output "A" is connected to the "BC" input – an input at the "A" input will then give you a division by twelve at the "D" output.

To reset the 7492 to BCD count of zero, both reset "0" inputs must be at logic 1. At least one of the resets must be at logic 0 for proper counting. Like the 7490, the 7492 counting occurs on the negative-going edge of the input pulse.

Another counter which is similar to the 7490 is the 7493 4-bit binary counter, which can count to 16 or divide by 2, by 4, by 8, and by 16.

The diagram and pinout of the 7493 are shown in Fig. 9.

With no external connection, an input at "A" (pin 14) will give an output divided by 2 at the "A" output (pin 12). An input on the "B" input (pin 1) will give an output divided by 2 at output "B" (pin 9), divided by 4 at output "C" (pin 8), and divided by 8 at output "D" (pin 11).

For the divide-by-16 operation, output "A" is connected to the "B" input. An input at the "A" input will then give you a division by 16 at the "D" output.

To reset the 7493 to count zero, both reset "0" inputs must be at logic 1. At least one of the resets must be at logic "0" for proper counting. Counting will occur on the negative-going edge of the input pulse.

The 74176 is a divide-by-2, divide-by-5 or divide-by-10 counter with an added feature over the other counters we have looked at. It has the ability of strobed parallel entry. This lets the counter be "programmed," and also lets it be used as a 4-bit latch.

The 74176's diagram and pinout are shown in Fig. 10.

To use this IC as divide-by-2 or divide-by-5, no external interconnections are required. The strobe (pin 1) and the reset (pin 13) are held at logic 1. An input signal at input Cp1 (pin 8) will give an output divided by 2 at output Qc (pin 2). An input at Cp2 (pin 6) will give an output divided by 5 at output Qd (pin 12).

For use as divide-by-10, connect the D input (pin 11) to the Cp1 input (pin 8). A clock input signal at Cp2 (pin 6) will give an output divided by 10 at the Qa output (pin 5). As in the divide-by-2 and 5 operation, when used as divide-by-10, the strobe and the reset are held high.

To use the 74176 as a

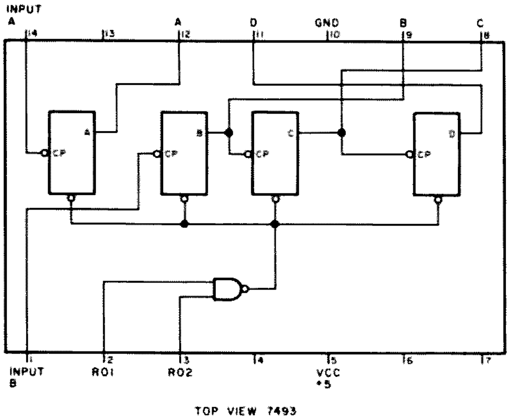

Fig. 9. Diagram and pinout of 7493.

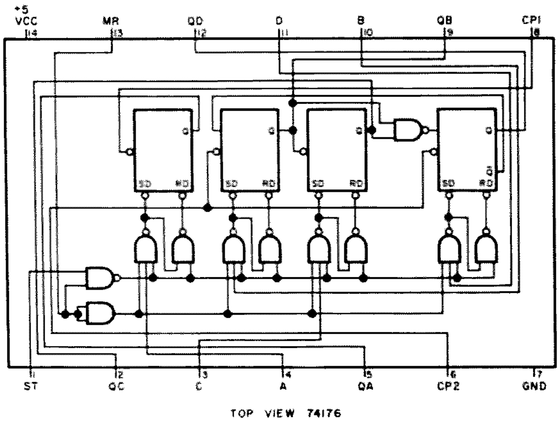

Fig. 10. Diagram and pinout of 74176.

counter, the Qa output (pin 5) is connected to the Cp2 input (pin 6). The input is applied to the Cp1 input (pin 8) and the count is obtained at outputs Qa, Qb, Qc, and Qd (pins 5, 9, 2 and 12). The reset (pin 13) is used to reset the counter to BCD count "0". Put high for counting and low to reset.

The strobe input is used for the parallel entry feature of the 74176. When the strobe (pin 1) is high, inputs A, B, C, and D (pins 4, 10, 3 and 11) have no effect on the outputs. When the strobe is put low, the outputs will change to agree with the data inputs independent of the state of the clock inputs. This feature will allow the IC to be "programmed" or preset to any count, not just "0".

The parallel entry will also allow use of the 74176 as a 4-bit latch. The data outputs Qa, Qb, Qc, and Qd will directly follow the inputs A, B, C, and D while the strobe is low, but will remain unchanged when the strobe is high and the clock inputs are inactive.

The counters that have been discussed here are only a small sample of the ones that are available. With counter ICs, as with simple gates, the best way to find out just how they work is to use them. All ICs listed in this article are available for under one dollar from advertisers in *73 Magazine*, so pick out one or two and start experimenting and then start building. ■

Inexpensive Variable DC Supply

-- easy and quick

Charles O. Klawitter W9VZR
4627 North Bartlett Avenue
Milwaukee WI 53211

It is extremely handy to have a source of variable dc energy in the ham shack. The usefulness of this device encompasses many areas. For instance, many of today's projects are built around semiconductors which require various dc voltages. Much of the military surplus available requires either 12 V dc or 24 V dc sources. You may not want your final conversion to operate on this source, but it can be very helpful to see if the equipment will function on its original source voltage before converting it. Those people active as mobilers certainly could use a husky supply to test that new mobile rig. Obviously, anything that is battery operated could be run, tested, or repaired with the help of this electronic wonder. It might even help you start your car some cold winter morning.

As you can see from the schematic, it is simply a variable autotransformer feeding a husky 30 V transformer into a bridge rectifier. The filter is a large capacitor. It would be nice to have a 30 A choke, but the filter shown has been satisfactory for all of the uses previously discussed.

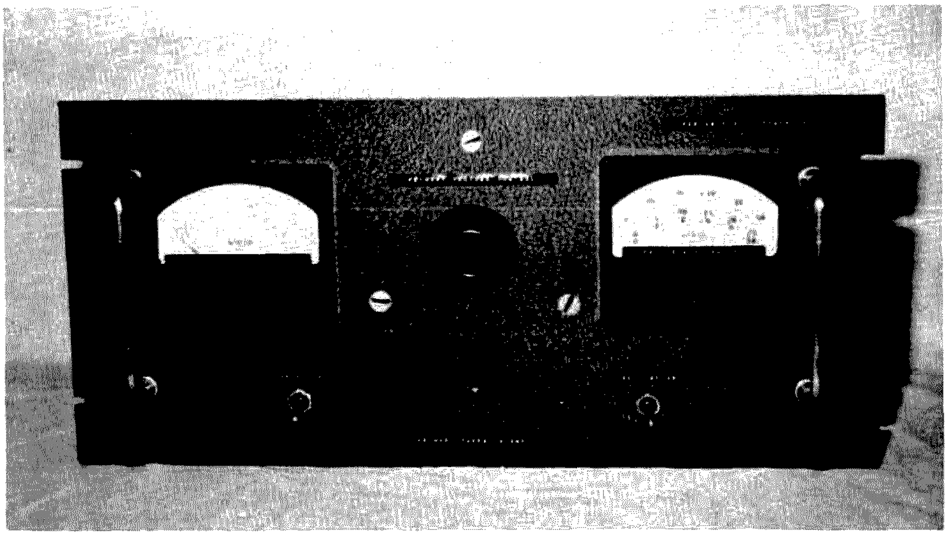
Well, now that I have established two major facts, its simplicity and its usefulness, let's build it.

You may skip this part of the article if you have a transformer or are going to purchase one. The transformer for this unit was a modified TV transformer. I located the heaviest one in the junk box. By the way, this was my first attempt at rewinding a transformer, and if I can do it, you probably can also.

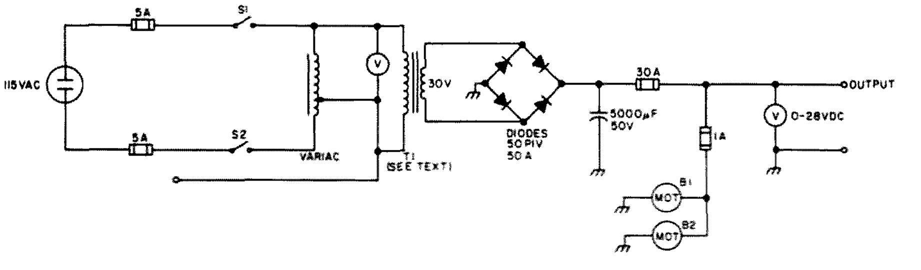
First remove the outer shell and the laminations. It may be necessary to use a little force to accomplish this. Never hit the laminations directly with a hammer; use a mallet or a block of wood with your hammer. Take care to preserve the leads from the windings.

Next, remove the secondary windings. Generally they are the outer windings. When you remove the 6.3 V filament winding, count the number of turns. It probably will consist of approximately twelve turns. Usually this type of transformer has a two turns per volt ratio. Retain this information for rewinding the secondary.

Finally, rewind the secondary; I used number 12 copper wire with a thick thermoplastic insulation. I used this wire because I had it

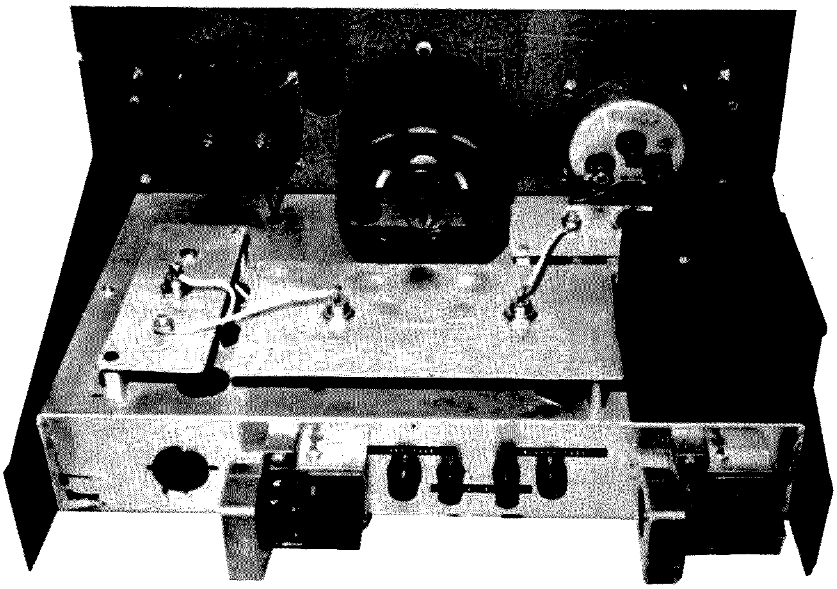


Front view showing layout of voltmeters, variac, control, S1, S2, and fuses. The handles are very functional because of the weight of the unit.



left over from wiring my wife's dryer. Obviously, an enamel or formvar insulated wire is suitable. As you are winding the secondary, check to be sure that the laminations will fit. I was able to get about sixty turns on the secondary – hence thirty volts. Using wire with thinner insulation, you can probably get several more turns.

The diodes were surplus units which were mounted on homemade heat sinks. The heat sinks were made from 1/8" thick aluminum scrap. I used about 12 square inches for each diode. The heat sinks were mounted on one inch ceramic pillars above the chassis to promote convection. Several holes were drilled in the chassis below the heat sinks; there was a bottom plate attached and two small 24 V dc surplus blowers were mounted on the back of the chassis. The output of the power supply was used to power the blowers. Even at five volts input, the blowers would move some air. The blowers really aren't necessary until the supply is run at high current output over a five to ten minute period of time.



Rear view showing general layout of diodes and heat sinks, output and blower fusing, blowers, and line input.

The toggle switch, S2, which removes the variac from the transformer and places the line voltage there instead, is used when there is a load which will greatly surpass the rating of the variac.

This unit has been used for everything from repairing transistor radios to operating dynamotor powered mobile equipment of the 12 V, 30 A variety. ■

exchange, about 7 miles away at Belfair, Wa., and circled the building with a $4 BC receiver. It was easy to find the spots on the walls where the noise peaked. Local phone company employees blamed the trouble on the power people, refusing to believe that any phone equipment could cause radio interference. They were so insistent in their belief that they didn't report interference to local headquarters in Seattle. They finally told me to tell it to FCC.

FCC contacted Seattle engineering. After some days I called engineering, and they said they would do something about it. It has been 5 weeks of passing the buck, and until intervention by FCC, there was no action at all. They will tell you anything, but do nothing.

The trouble finally turned out to be the battery charger at the exchange office. They haven't fixed it yet, and I have notified them that my hobby involves circulation of audio currents through widely separated grounds.

So, in the case of a pulse type noise, or a sharp rattling noise, particularly on 160 meters, check your phone line for the source. It is to be hoped that the management of your telephone exchange will be more cooperative than the locals. I don't know if the chargers used by General Telephone subsidiaries cause the same type of interference.

SPLENDID SERVICE

About 4 months ago I wrote you and complained about the very bad postal service and very late delivery of the *73 Magazine*.

I don't know how you are doing it or what you have done, but I now receive your excellent magazine for 3 months in succession the first week of the current month the magazine comes out. To beat everything, I received the December issue at the end of November. Needless to say, I want to thank you and your staff very much for this splendid service.

I received this subscription to your magazine from my good friend Ed Dombert W2PCP, and this is a very valued present. Living on this island "down south of you," it is annoying how long it sometimes takes to receive the mail from up north. Here again, you beat the others, and once again, thank you and well done.

William Vander Greft PJ2WI
Curacao, Neth. Antilles

SANDY CLAWS

I received the sample copy of *73* today which I had requested some time ago when your subscription offer came.

Looks like you do have a pretty good magazine. However, it sure let me down the very first thing. You see, I have been taking another magazine for several months just to get the ad section, because I want a good used SSB/CW rig. So, right off the bat, I went to the back of *73* and searched all the way to the front. Then from the front all the way to the back. Plenty of good-looking new stuff. But if I give around $700 for something to play with, I think it should also cook my breakfast! So the answer is a good $400 used outfit.

I certainly appreciate this opportunity to see what *73* is like and after my other subscription expires and I get a new rig, perhaps I'll try it. With tax time here and the usual rough time with Santa Claus just over, things are pretty rugged, even in Dixie. (If inflation gets much worse, Sandy Claws may find himself going down the drain instead of the chimney.)

Jim Miller
Waterloo SC

THE BROAD SPECTRUM

This note is to inform you that I have been very pleased by the excellent service and response of your advertisers, namely Ramsey Electronics, James Electronics, and many others.

I might also add that your many construction articles are very FB and your publication covers the broad spectrum of amateur radio very well.

Alex Hellman W2OEQ
Woodhaven NY

29.6

I read Martin Greenbaum's article "Ten Meters: Dead or Alive?" with great interest. However, there was a gross oversight in his article, especially with the great interest there is today in FM. 29.6 MHz has for years been the FM channel on ten meters, and you haven't worked DX until you've worked someone full-quieting 3000 miles away, or worked your next-door neighbor through a repeater 3000 miles away. With the low cost avail-

Form 700 Provisional. *Number* 14120

LICENSE FOR GENERAL AMATEUR RADIO STATION

(General or restricted)

DEPARTMENT OF COMMERCE
BUREAU OF NAVIGATION
RADIO SERVICE

Pursuant to the act to regulate radio communication, approved August 13, 1912, E. G. Schalkhausser *, a citizen of the State of* [illegible] *, having applied therefor, is hereby granted by the Secretary of Commerce, for a period of* one *year , on and subject to the restrictions and conditions hereinafter stated and revocable for cause by him, this License to use or operate the apparatus for radio communication (identified in the Schedule hereinafter) for the purpose of transmitting private radiograms or signals, notwithstanding the effect thereof extends beyond the jurisdiction of the State or Territory in which the said station is located: Provided, That no interference other than may result under the restrictions contained in this License shall be caused with the radio communication of stations of the Government of the United States or licensed stations.*

2. The use or operation of apparatus for radio communication pursuant to this License shall be subject also to the articles and regulations established by the International Radiotelegraphic Convention, ratified by the Senate of the United States and caused to be made public by the President, and shall be subject also to such regulations as may be established from time to time by authority of subsequent acts and treaties of the United States.

3. The apparatus shall at all times while in use and operation be in charge of a person or persons licensed for that purpose by the Secretary of Commerce, and the operator of the apparatus shall not wilfully or maliciously interfere with any other radio communication.

4. The station shall give absolute priority to signals or radiograms relating to ships in distress; shall cease all sending on hearing a distress signal; and shall refrain from sending until all the signals and radiograms relating thereto are completed.

5. The station shall use the minimum amount of energy necessary to carry out any communication desired, and the transformer input shall not exceed one ~~one-half~~ *kilowatt* *

6. The station shall not use a transmitting wave length exceeding 200 meters.

7. The station shall not use a transmitter during the first 15 minutes of each hour, local standard time, whenever the Secretary of Commerce by notice in writing shall require it to observe a division of the time, pursuant to the Twelfth Regulation of the act of August 13, 1912.

8. The President of the United States in time of war or public peril or disaster is authorized by law to close the station and cause the removal therefrom of all radio apparatus, or may authorize the use or control of the station or apparatus by any department of the Government upon just compensation to the owners.

9. The Secretary of Commerce and Collectors of Customs or other officers of the Government authorized by him may at all reasonable times enter upon the station for the purpose of inspecting and may inspect any apparatus for radio communication of such station and the operation and operators of such apparatus.

10. The apparatus shall not be altered or modified in respect of any of the particulars mentioned in the following Schedule except with the approval of a radio inspector, or other duly authorized officer of the Government. 11—300

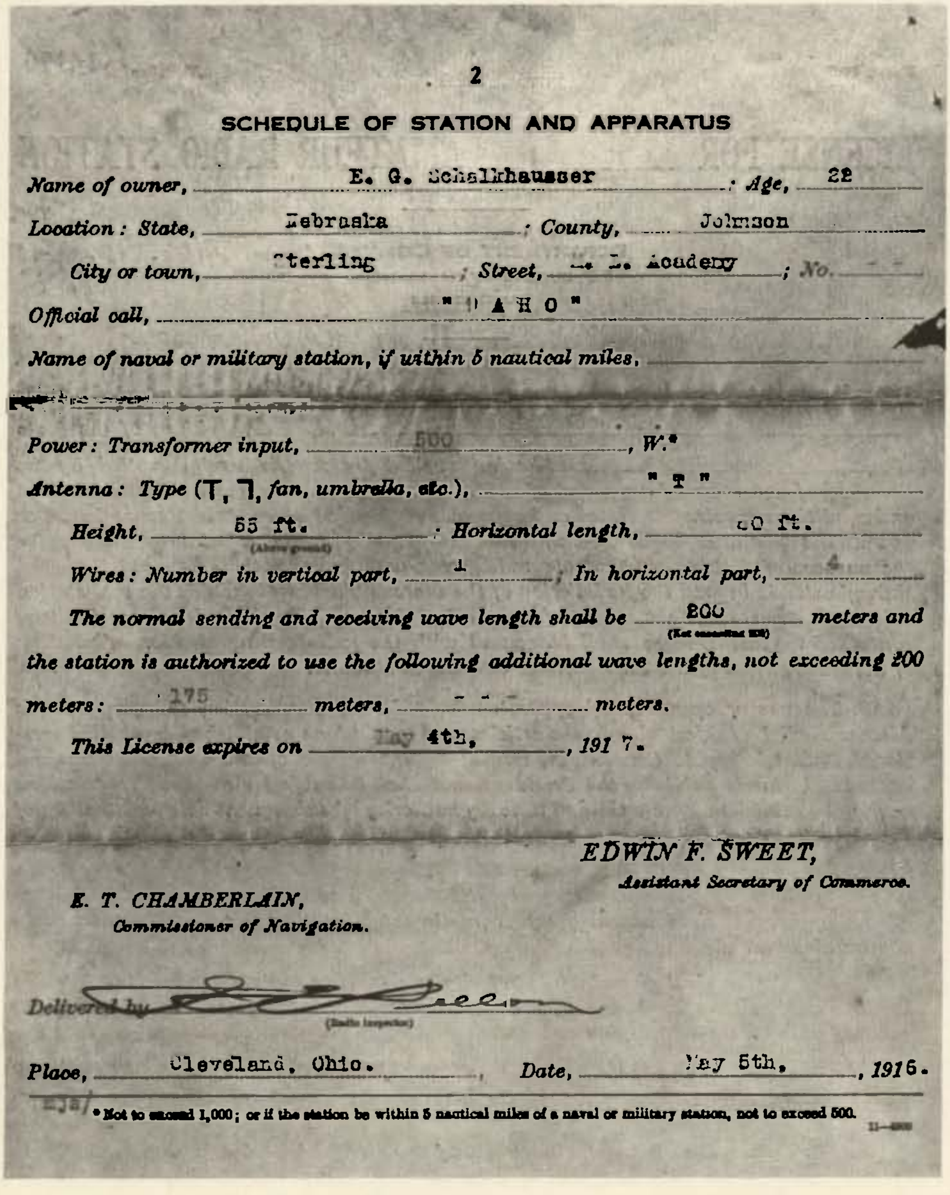
* Strike out "one" if the station be within 5 nautical miles of a naval or military station; otherwise strike out "one-half."

One of the first amateur licenses issued shortly after they were required.

The History of Ham Radio

- - part I

When trying to get just a glimpse of wireless history in a nutshell, it is traditional to lay most emphasis on the years from 1910 and on. This period coincided with radio rules and regulations, the three Rs, being formulated by the United States government. We then project the general accumulation as far as 1927-1928, after which time some degree of order was again established in the radio industry, overall.



2

SCHEDULE OF STATION AND APPARATUS

Name of owner, E. G. Schalkhausser; *Age,* 22

Location: State, Nebraska; *County,* Johnson

City or town, Sterling; *Street,* .. L. Academy; *No.* - -

Official call, " 9 A H O "

Name of naval or military station, if within 5 nautical miles,

Power: Transformer input, 500, *W.**

Antenna: Type (T, ˥, fan, umbrella, etc.), " T "

Height, 55 ft. (Above ground); *Horizontal length,* 60 ft.

Wires: Number in vertical part, 1; *In horizontal part,* 4

The normal sending and receiving wave length shall be 200 (Not exceeding 200) *meters and the station is authorized to use the following additional wave lengths, not exceeding 200 meters:* 175 *meters,* - - - *meters.*

This License expires on May 4th, *191* 7.

EDWIN F. SWEET,
Assistant Secretary of Commerce.

E. T. CHAMBERLAIN,
Commissioner of Navigation.

Delivered by (Radio Inspector)

Place, Cleveland, Ohio. *Date,* May 5th, *191*6.

* Not to exceed 1,000; or if the station be within 5 nautical miles of a naval or military station, not to exceed 500.

In telling our story, it is impossible to refrain making pertinent insertions of interest. There were many occurrences during those early years that stand out vividly in memory and need telling. Those beginning years were mostly of pioneering and exploring, bringing forth many discoveries and inventions in rapid order, in very short periods of time.

1909

To begin with, let me set the year 1909 as a reference. Why 1909? We will become aware of the reason as we review the history in relating the *magic that is wireless*.

And it sure was magic to everyone in those days, believe me! Let me take a short glimpse into the past history of wireless. There were no laws on the books. There were no rules or regulations pertaining to wireless. The general public was not even aware that radio waves existed. They had no inkling of what was meant by communicating without wires. Practically nothing was known about electricity. All this was a mystery.

1888

In 1888, just 89 years ago, a German Scientist made a discovery when he sensed

that there was something present in the vicinity of an electrical spark in a Lyden jar discharge. This elementary discovery made by Heinrich Hertz set the stage for many scientific investigations. They were carried on in university laboratories, stimulating research in the field of electromagnetic waves.

1892

About this time, along came Marconi from Italy. He was born in the year 1874. At the age of 18, while a freshman at the University of Bologna, Marconi discovered that an electric discharge from a condenser could be detected. This made possible the transmission and reception of signals over some distance. Playing around and experimenting for four years, he finally went to England, where he demonstrated his findings and equipment.

1896

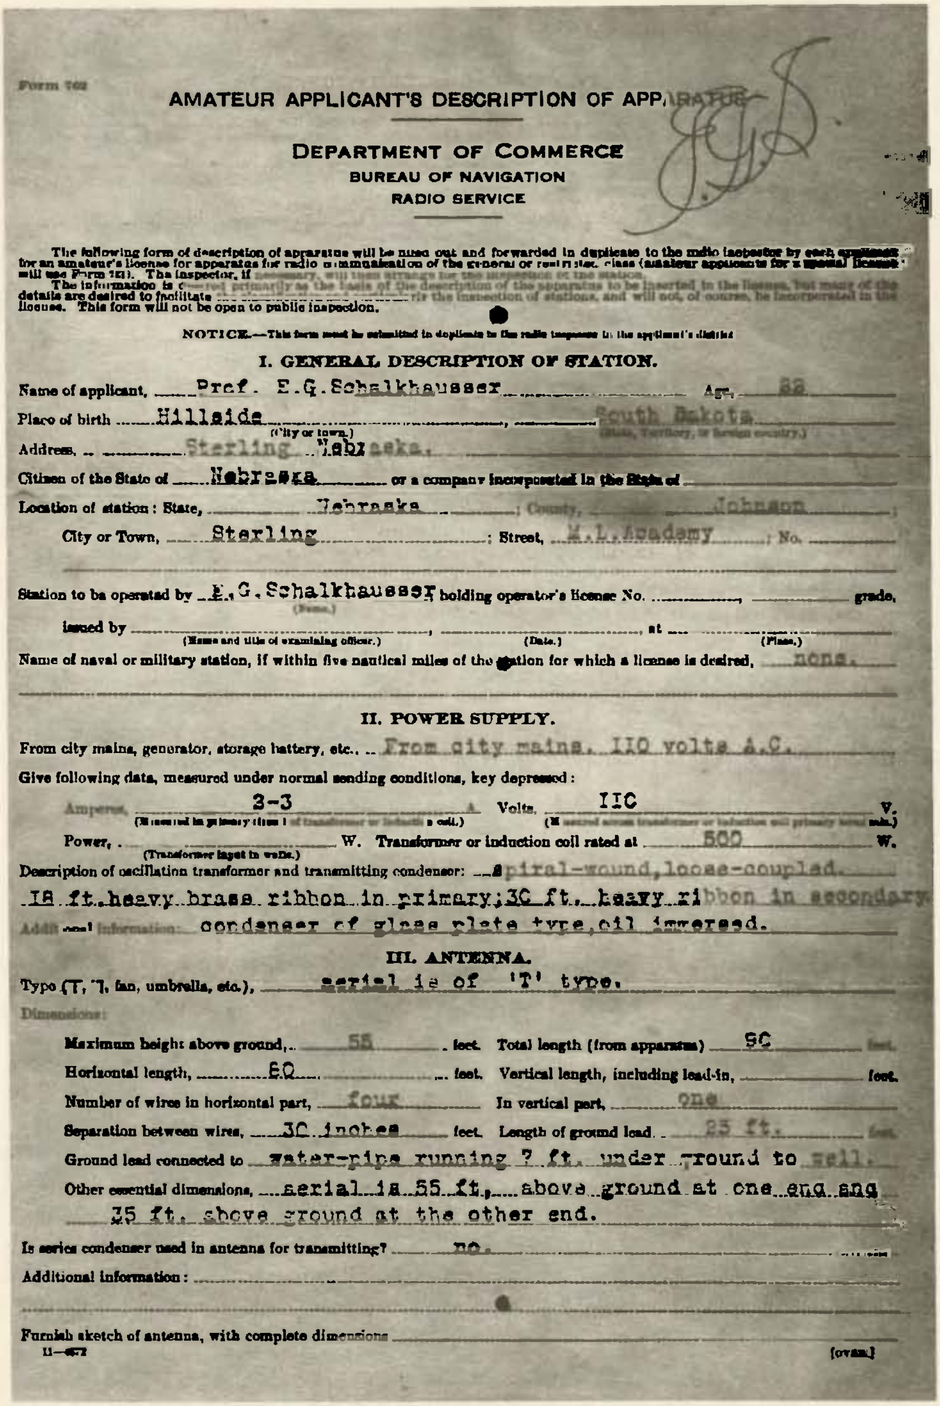
In 1896, Marconi obtained a British patent for *wireless telegraph apparatus using electricity*. How utterly novel and primitive that description sounds today. And that was only eighty-one years ago! (At that time I was 3 years old, but do not recall the incident!)

1897

Within a year, commercial interests became aware of the possibilities in the application and use of Marconi's invention and organized the Wireless Telegraph and Signal Company, Ltd., in England.

1899

In 1899, Marconi and his assistants succeeded in sending signals across the English channel with their crude equipment. The main bottleneck was their iron filing coherer for detection of signals. The use of galena, silicon, or carborundum was not yet known for detecting wireless signals. In this same year, the Marconi Wireless Company of America was established.



Form 702

AMATEUR APPLICANT'S DESCRIPTION OF APPARATUS

DEPARTMENT OF COMMERCE
BUREAU OF NAVIGATION
RADIO SERVICE

The following form of description of apparatus will be filled out and forwarded in duplicate to the radio inspector by each applicant for an amateur's license for apparatus for radio communication of the general or restricted class (amateur applicants for a special license will use Form 761). The inspector, if necessary, will then arrange for the inspection of the station.
The information is desired primarily as the basis of the description of the apparatus to be inserted in the license, but many of the details are desired to facilitate the inspection of stations, and will not, of course, be incorporated in the license. This form will not be open to public inspection.

NOTICE.—This form must be submitted in duplicate to the radio inspector in the applicant's district.

I. GENERAL DESCRIPTION OF STATION.

Name of applicant, Prof. E.G. Schalkhausser Age, 22
Place of birth Hillside (City or town.), South Dakota (State, Territory, or foreign country.)
Address, Sterling Nebraska.
Citizen of the State of Nebraska or a company incorporated in the State of
Location of station: State, Nebraska; County, Johnson
City or Town, Sterling; Street, M.L.Academy; No.
Station to be operated by E.G. Schalkhausser (Name.) holding operator's license No. , grade,
issued by (Name and title of examining officer.), (Date.) at (Place.)
Name of naval or military station, if within five nautical miles of the station for which a license is desired, none.

II. POWER SUPPLY.

From city mains, generator, storage battery, etc., From city mains, 110 volts A.C.
Give following data, measured under normal sending conditions, key depressed:
Amperes, 3-3 A. Volts, 110 V.
Power, W. (Transformer input in watts.) Transformer or induction coil rated at 500 W.
Description of oscillation transformer and transmitting condenser: Spiral-wound, loose-coupled.
18 ft. heavy brass ribbon in primary; 30 ft. heavy ribbon in secondary.
Additional information: condenser of glass plate type, oil immersed.

III. ANTENNA.

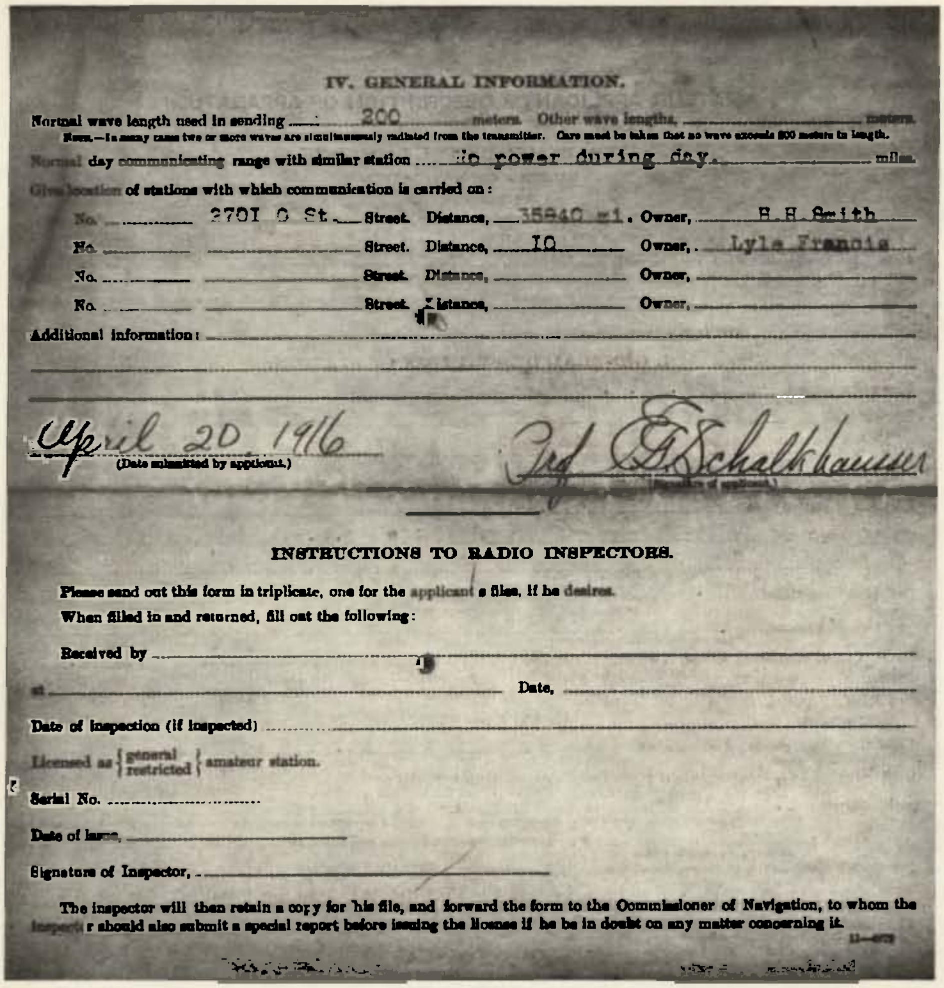
Type (T, ⅂, fan, umbrella, etc.), aerial is of 'T' type.
Dimensions:
Maximum height above ground, 55 feet. Total length (from apparatus) 90 feet.
Horizontal length, 60 feet. Vertical length, including lead-in, feet.
Number of wires in horizontal part, four In vertical part, one
Separation between wires, 30 inches feet. Length of ground lead, 25 ft. feet.
Ground lead connected to water-pipe running 7 ft. under ground to well.
Other essential dimensions, aerial is 55 ft. above ground at one end and 35 ft. above ground at the other end.
Is series condenser used in antenna for transmitting? no.
Additional information:
Furnish sketch of antenna, with complete dimensions
(over.)

1900

At the turn of the century, the English company changed its name to Marconi Wireless Telegraph Company, Ltd., to be more in keeping with current developments.

1901

In 1901, Marconi and two of his engineers came across the Atlantic to set up their wireless equipment in Halifax, Newfoundland. They succeeded in receiving messages across the waters from a station transmitting out of Polduh, England. All this on very long wavelengths, since the shorter ones were still undiscovered. By this time, many ships at sea were installing transmitting and receiving equipment and many shore and inland locations established communication centers.



IV. GENERAL INFORMATION.

Normal wave length used in sending .... 200 .... meters. Other wave lengths, ... meters.

Note.—In many cases two or more waves are simultaneously radiated from the transmitter. Care must be taken that no wave exceeds 200 meters in length.

Normal day communicating range with similar station .... No power during day. .... miles.

Give location of stations with which communication is carried on:

No. .... 2701 O St. .... Street. Distance, 35840 mi. Owner, B. H. Smith

No. .... Street. Distance, 10 .... Owner, Lyle Francis

No. .... Street. Distance, ... Owner, ...

No. .... Street. Distance, ... Owner, ...

Additional information: ....

April 20 1916 (Date submitted by applicant.)

Fred G. Schalkhauser (Signature of applicant.)

INSTRUCTIONS TO RADIO INSPECTORS.

Please send out this form in triplicate, one for the applicant's files, if he desires.

When filled in and returned, fill out the following:

Received by ....

at .... Date, ...

Date of inspection (if inspected) ....

Licensed as {general / restricted} amateur station.

Serial No. ....

Date of issue, ...

Signature of Inspector, ...

The inspector will then retain a copy for his file, and forward the form to the Commissioner of Navigation, to whom the inspector should also submit a special report before issuing the license if he be in doubt on any matter concerning it.

An apparatus description, one of the required parts of getting an early ham ticket.

1902

By 1902, a great deal of interest was shown in the application of this relatively new phenomenon. Gradually, better detecting devices were invented and larger stations were erected, in Europe, America, and other countries.

The station of 9AHO.

One should call attention to the contributions made at this time by Sir J. J. Thompson, a British scientist, who had discovered the electron, enclosed in a vacuum tube. It was a sequel to Edison's invention of the light bulb.

1904 and 1906

This led to the development of the use of vacuum tubes in detecting wireless signals, where J. A. Fleming in 1904 and Lee DeForest in 1906 made their contributions. While the sagas of the sea kept the newspapers busy and the public talking of the great wonders of wireless and its possibilities, what do you suppose was going on among the younger scientists across the country, especially in the eastern part of our United States? All of these intriguing possibilities of radio did not just belong to commercial companies – *by no means!*

Here we digress a bit and look into the back rooms and woodsheds around the country, taking note of the enthusiasm and the influence that wireless had produced among the young. We need to find out what was going on in these areas, since this part of early wireless history is vital in following the progress of the new discovery.

1909

This brings me to the year 1909, previously referred to. While the commercial interests considered wireless in terms of their restricted domain, we find a group of "wireless kids" in New York, no more than ten in number, all in their teens, getting together and forming a Junior Wireless Club on January 2, 1909. They were putting together metal plates, wires, and iron filings, making their own coherers, winding coils and other paraphernalia, and succeeding in sending dots and dashes according to the Morse code, between their homes, from block to block, and even across miles. They were listening in to what was going on, hearing the mes-

JUNIOR WIRELESS CLUB, LTD.

EACH MEMBER MUST HAVE MADE HIS OWN STATION.

W. E. D. Stokes, Jr., Its President—Headquarters at the Ansonia Contains Much Apparatus—Club to Go to Washington to Oppose Pending Bill.

It is somewhat dangerous to attempt to enter the clubroom and experimental station of the Junior Wireless Club, Ltd., without a guide, for the officer in charge dispenses with the necessity of lock and key by having the knob charged with electricity to give the unexpected and unexpecting visitor what he terms a "nice little shock."

But when proper guidance is secured from the club's young president, who maintains headquarters at his home, the Ansonia, many marvels and [illegible] may be observed with some degree of security. W. E. D. Stokes, Jr., president, aged 11 years, points out the pitfalls.

"Look out. Don't step on that zinc plate!" says he. "It's charged!" And you look out and don't step.

The clubroom and receiving station is imposing, almost formidable despite its somewhat small extent. In addition to the wireless telephone instruments at one side of the window, the sending station across the way and the aerials connecting with three conduits above, many other things more or less electric add to the effect. A big electric turning lathe occupies one side of the room; numerous vari-colored models of aeroplanes—which the manufacturer asserts really go when wound up—hang from wire complexities overhead; zinc plates, worse than they look, are not to be ignored.

In fact it is not safe to put a hand on the most innocent looking object on first reconnoitre. A big box beneath the battery and motor table filled with perfectly staid appearing earth and plants which thrive on the rays of a makeshift sun specially arranged out of a [illegible] candle power electric bulb is not what it would seem. Those plants—roots, branch, leaf or blossom—are electrified and emit sparks when invited. On the side walls high and low, on the ceiling and suspended therefrom, bulbs of every conceivable variety, shape and power transform the little room into an Aladdin cave of brilliancy.

"I'm always looking around at bulbs," says the president, "and when I see a new kind I try it."

So there they are, long and slim, short, fat and round, but all shining and beaming out dazzlingly. The blueprints of scientific aspect which adorn one side of the wall, posters of the Postal Telegraph and Cable Company variety, illuminated letter placards bearing such legends as "No Smoking," "S. W. Co." Stokes Wireless Company and last but not least printed lists of wireless signal stations and steamers with wireless equipment.

[illegible]

W. E. D. STOKES, JR., AND HIS WIRELESS TELEGRAPH

This article appeared in a New York City newspaper early in 1910. The boy in the picture is the first president of the Junior Wireless Club, later renamed the Radio Club of America.

sages floating around between ships and shore stations. This was real fascination!

1910

Naturally there were bound to be conflicts developing, especially between the commercial companies and the "interlopers." Interference occurred and became objectionable for "the big boys." So in the following year, 1910, the existing problems were brought to the halls of Congress, to find ways and means to regulate wireless communication and define domains. True, the ether was free space and belonged to everybody, but the commercials and their interests sought to have vested right in their use of this "free" space. Thus, the conflict . . .

The conflict was brought to a head in the introduction of two bills, one in the House and one in the Senate. House bill #23495 and Senate bill #7243 were introduced. The senator strongly in favor of these bills was none other than Chancy Depew of New York, which was the bailiwick where the interlopers were operating. The contents of the bills were strongly against any use of the airways by anyone except the commercials. The teenagers with their homemade equipment and their determination, organization, and above all, their spirit, had other ideas. They wrote a letter to Chancy and told him so. Here we note something which will be of interest to all of you. The boys of the Junior Wireless Club had a meeting, selected their representatives, and asked to have a hearing in Washington. They composed another letter to Chancy Depew, were granted a hearing, and on April 28, 1910, were given the privilege of presenting their case. Believe it or not, these boys won their right to go on experimenting as they had done before. This Junior Wireless Club had performed like veterans in the halls of Congress, and to them and many others went the freedom of the ether for many years to come.

1911

So in 1911, the enthusiasm on the part of radio amateurs grew tremendously. In the same year, the Junior

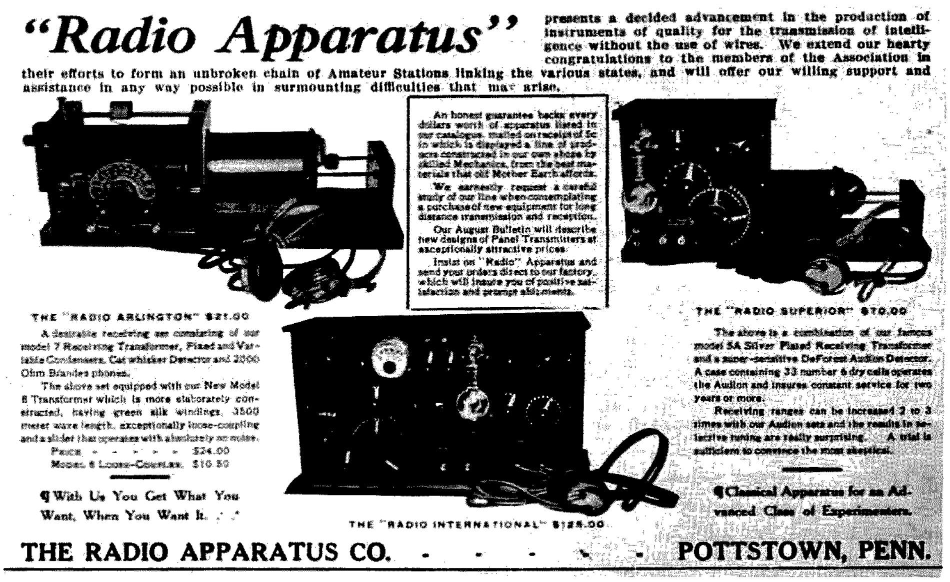
Wireless Club changed its name to The Radio Club of America, and remains so to this day. The members became notables in wireless. The club was held in very high esteem, especially after their confrontation with Congress and their display of courage and dedication for a cause dear to their hearts and right in principle.

By 1911, every wireless company and operator on ship and shore knew that regulations were a necessity to hold down interference in radio communication. An Act, dated June 24, 1910, authorized by our Department of Commerce, Bureau of Navigation, became what at that time was considered the law of the land regarding radio transmission and reception. This Act consisted of four sections, all very general, and was labeled An Act to Require Apparatus and Operators for Radio Communication on Certain Ocean Steamers.

1912

On July 23, 1912 (two years later), and then only pertaining to section one of the four sections, the Act was amended, spelling out some specific details concerning operators and ships at sea. From then on, all transmitting stations would have to apply for a license to operate. The law was not too specific. It had loopholes, and many inland stations, especially amateur radio enthusiasts and experimenters, went about hooking up induction coils and going on the air with call letters assigned by themselves. For instance, a "one inch" spark coil was considered to be limited to no further than eight or ten miles, so did not fall within the law crossing state borders! What a "primitive" concept of wireless in those days. The type of signal coming from these amateur operated coils did not conform to any known bandwidth or frequency standard. A signal was "just a signal."

At this time, a number of wireless organizations blossomed. Notable among these were 1) The Institute of Radio Engineers, 2) The American Radio Relay League, and 3) The National Amateur Wireless Association. Up to this time there was very little literature or published information available. It did not take long for these to appear. Soon small companies issued store catalogs offering everything from loose couplers to crystals and crystal holders, headphones, and all sorts of gear to get the amateur started. Enthusiasm ran high. Wireless was a new found discovery and appealed to the young as well as to the old. Wireless could be used to span great distances and for so many experiments. The fascination of distant communication without wires was gripping and overwhelming.



As soon as radio became popular as a hobby, equipment began appearing on the market. Note the flamboyant style of the copy, typical of the period. This ad appeared in 1915.

Issued in January 1917, this certificate was one of the first of the "awards" that hams have always displayed with pride on the walls of the shack.

WHAT A GOVERNMENT LICENSE IS, AND HOW TO GET ONE

The law governing the operation of amateur stations was not passed with the idea of silencing the amateur operator—on the contrary, it is an official recognition of the amateur's rights—and a Government license carries with it advantages and privileges that otherwise the amateur would not enjoy—that is, if he keeps within the law. The law as it relates to the operation of amateur stations in itself is not a strict one. If you have a receiving station only, it is not necessary for you to get a license. If you operate a sending whose power is great enough to reach beyond the boundaries of the state you are located in, or to interfere with the licensed stations in the state, the law says you must have a license. Briefly, it states that your wave length shall not exceed 200 meters and your transformer input shall not exceed 1 KW. Or if your station is located within five nautical miles of a military or naval station, your transformer input shall not exceed ½ KW.

The license is free, and the only requirements are, that you answer correctly the questions asked in the forms sent you, and that you are able to transmit and receive messages at the rate of at least 5 words a minute To get one, write the Radio Inspector, Department of Commerce, Bureau of Navigation of the District headquarters nearest you, and ask for Form 756, (Application for Operator's License) and Form 757 (Application for License for Land Station) both of which will be forwarded to you. If you have a license, Official Call Letters are assigned you which no one else can use. You know what you can do, and what you can't do, and no one can interfere with you in any way so long as you obey the law. For your own protection you should get one.

In 1915, the Central Radio Association issued its Blue Book, a reference text for early amateurs. It included this explanation of why licenses were required.

1914

Hiram Percy Maxin was one individual who could come up with the right ideas at the right time, and the ARRL was his heritage. No sooner had this enthusiasm caught fire when World War I broke out in Europe in 1914.

1917

The conflict went on for several years and sure enough, the United States became involved in 1917. All radio amateurs received notices to dismantle their equipment. Many joined the services in one capacity or other, many into the Signal Corps where their training and experience as radio operators was greatly appreciated by the government.

To be continued.

Remember the Windom!

-- is this the world's simplest five band antenna?

This antenna was one of the most popular antennas for amateur use, and it deserves more attention than it gets now, although it was first designed in 1929. In that year, two amateurs, John Byrne and Ed Brooke of Bell Telephone Laboratories, under the direction of Professor W. L. Everitt of the Department of Electrical Engineering, Ohio State University, experimented with and perfected this antenna. It was reported in September, 1929, *QST* by Loren G. Windom, and therefore became known as the Windom antenna.

Its chief advantage is that it may be used on all even harmonics with a single wire feed. Since amateur bands are harmonically related, except 15 meters, it may be used without change for an all band antenna. By cutting it for 80 meters, it can also be used on 40, 20 and 10, without changing the properly placed single wire feedline.

The length of the antenna is determined by the formula, 468/frequency in kHz. Thus, for 3725 kHz the length will be 125'8". The distance of the feeder from the center is approximately 14% of the antenna length, or about 17'6". At this point there are no standing waves on the feedline. By tapping the feeder up on the plate tank until the transmitter loads properly, you can tune for whatever band you are operating in. See Fig. 2. The feeder is #14 wire, any length.

To reduce the chance of getting rf in the station, the method in Fig. 2(b) can be used, with link coupling to an external tuned circuit. This antenna at the feedpoint has an impedance of approximately 600 Ohms.

There has recently emerged a similar appearing off center fed antenna which is incorrectly called a Windom, as shown in Fig. 3. The theory is that this is fed at a 300 Ohm point with twinlead, which can then be transferred by a 4-1 balun to 75 Ohm coax. There is some controversy about this, but at any rate the feedlines should come away from the antenna at a right angle for at least a quarter wave length, and the equipment should be well grounded to prevent floating rf in the station. ■

The Agonies of Tower Raising

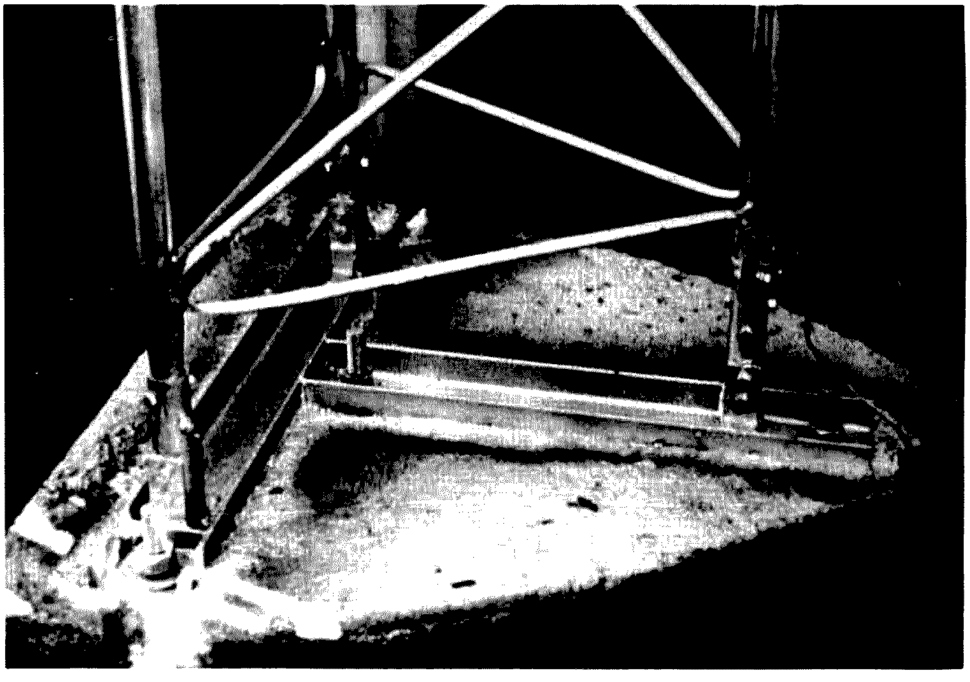
- - Murphy strikes again... as usual

For many years I debated, planned, and agonized over the purchase and installation of a decent-sized tower for my home station. Though money was a definite factor in the project, other considerations such as location, base configuration, type and size of tower, and local building ordinances presented the main concerns.

When using VHF/UHF (2 meters, 220 and 450 MHz), tower location and height become very important factors. The tower must be high for good communications and yet close to the rig since feedline losses mount with cable length. Based on this, I decided to use a 60 foot tower located a wall away from my equipment. For ease of installation and maintenance, I decided to use Universal's Model 14-60 self-standing aluminum tower with a hinged base.[1] This tower, according to the manufacturer, will support 14 square feet of antenna in an 80 mile an hour wind with a safety factor. The lack of the need of guy wires was a major consideration since guy anchors would mean more problems.

Having decided on the tower height and location, the next task was designing the tower base configuration. Normally this would not be a big deal – get some idiot to dig you a big hole and fill it with concrete – but what about a solid rock ledge of New York State granite for a backyard?

To solve this matter, I thought about employing a jackhammer to dig the hole. However, after consulting with a friend in the construction business, I decided against this expensive back-breaking procedure. I then considered a few sticks of dynamite, but notwithstanding the damage to the QTH, blasting permits were hard to come by. Discussing the matter on the local repeater WR2ABB, a friend WA2HSF advised using a core drill which bores a clean, round hole into rock. This matter being resolved, I finally checked out all local building and tower restrictions and ordinances to see that there were no laws forbidding my little project. Luckily, the laws were with me so out came the checkbook and the shovels and soon groundbreaking was at hand.



View showing the base with its four securing rods.

The photo shows the base and the four securing rods. The right side of the base is about 3-4 inches below ground level while the left side is about 7-8 inches. The holes for the rods were drilled with an electric core drill and a diamond/carbide bit. Both were rented from a local rental agency for $28/day. Each hole is 1½ inches in diameter, about 8-9 inches deep, and each took about 50-60 minutes to drill. The rods are 7/8 inch diameter steel and are threaded their entire length.

To secure the rods in the rock, commercial rock anchors (threaded Ring Wedge Cinch Anchors) were used.[2] These anchors are a combination iron wedge/metal ring/lead alloy unit. They are threaded on and over the rods and expanded within the hole through the use of a separate pipe and sledge hammer. I used three units in each hole as specified by the manufacturer. With this

arrangement, each rod can take a maximum tension test load of 14,440 pounds (57,760 pounds total) and a maximum shear test load of 36,130 pounds (144,520 pounds total). See Fig. 1.

Once the rods were set in place, the concrete for leveling the base was poured. Approximately 1¼ yards of concrete was required to make the base extend four inches above the ground level. The finished concrete had a comprehensive strength of approximately 3000 psi.

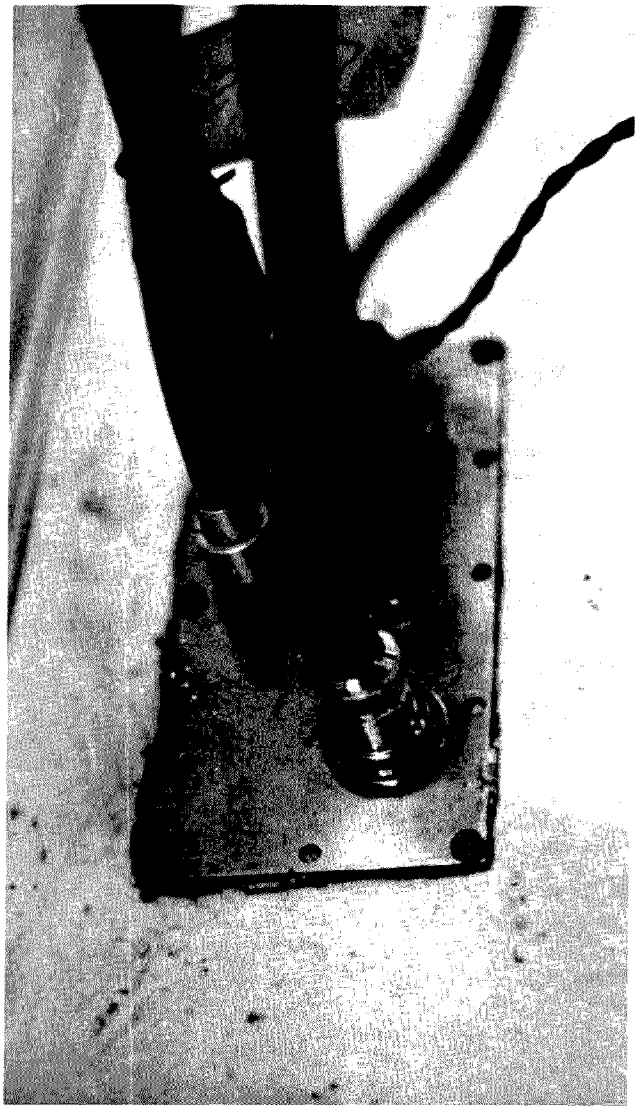
Leveling of the tower was straightforward once the concrete began to age. The flat-roof mount with hinged base was placed on the concrete and leveled. The bottom 10 foot section of the tower was put in place and leveled. Actually, this is a lie since it didn't work out that way. That is, two of the three legs were level while the third was way out of true. After a few minutes of puzzlement, the mystery was solved – the tower tapers inward from the bottom to the top to accept the next smaller section. A quick readjustment was made so that each leg of the tower was off perpendicular towards the center of the tower by the same amount. With this crisis passed, the concrete was allowed to age for seven days.

Now the second phase of the project began. A crew was assembled consisting of W2BEV, WB2COY, WB2CTH, WB2HDS, and WA2QWP. The first step was to put the tower together, 10 foot sections one at a time. Thanks to the hinged base, the tower could be constructed on the ground. Most of the sections had to be "horsed" together with a bit of grunting, but this made for a tight fit. The next step was attaching the coaxial cables and rotor wire. The cables should be placed on the inside of the tower so that they are not damaged on future climbing of the tower. This job was neatly accomplished thanks to Phelps-Dodge "Straptite" cable clamps.[3] The antennas, a commercial 8 element 2 meter yagi and an 11 element 220 MHz beam, were previously assembled on the mast and attached to the rotor at the top of the tower. A monitor-scanner antenna was side mounted on the tower completing the installation.

All of this work, however, was not without the curse of Murphy. In the process of making jumper cables between the antennas and feedlines, it was found that no one had had experience in attaching "N" connectors to RG/8 polyfoam coax. Well, as it turned out, it is almost impossible to do. Regular RG/8, no problem; polyfoam RG/8, forget it. A quick call to W2VAQ solved the jumper problem and saved the day.

The third, and most crucial, phase was now to be done – erecting the tower. Though we did not really expect it, raising the tower proved to be the biggest task of the day. Mathematically, the tower was only supposed to weigh 844 pounds at its lowest level to the horizon. This was calculated using the formula shown below, where H1 = Height from pivot point to rope attachment on tower, in feet; L1 = Length from pivot to pulling point, along horizontal, in feet; Wa = Weight of antennas, rotor, etc., in pounds; Wt = Weight of tower including cables, in pounds; A = Angle tower makes with horizontal, in degrees; H = Height above pivot point of rope pulling tower, in feet; L = Length of tower, in feet; T = Tension in rope, in pounds; and the following are assumed: 1.

$$T = \frac{L \times [\,(Wt / 2) + Wa\,] \times \cos A}{H1 \times \sin A - \operatorname{Arc\,Tan}[\,(H1 \times \sin A) - H\,] \,/\, (H1 \times \cos A + L1)}$$



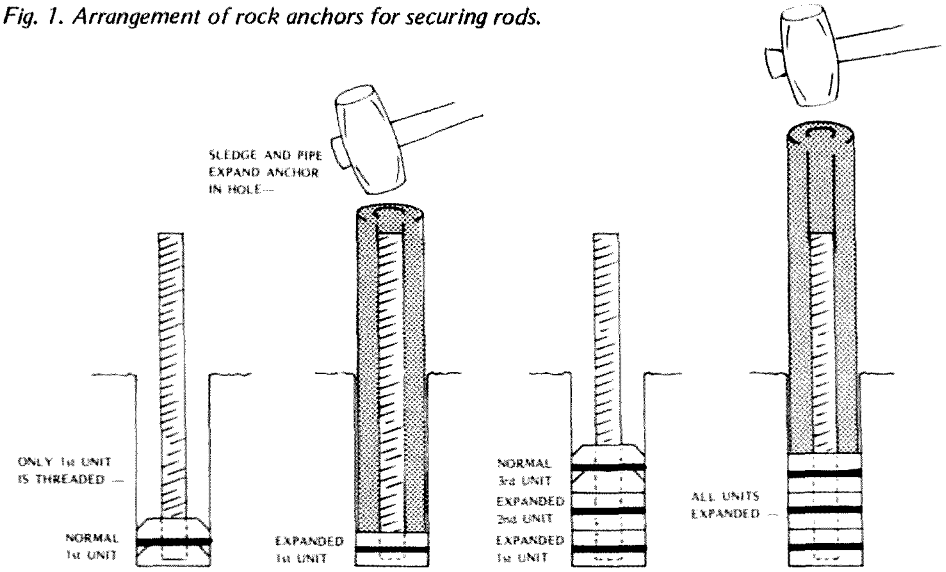
Connectors were installed on cables at the base of the tower and attached to the outside bulkhead.

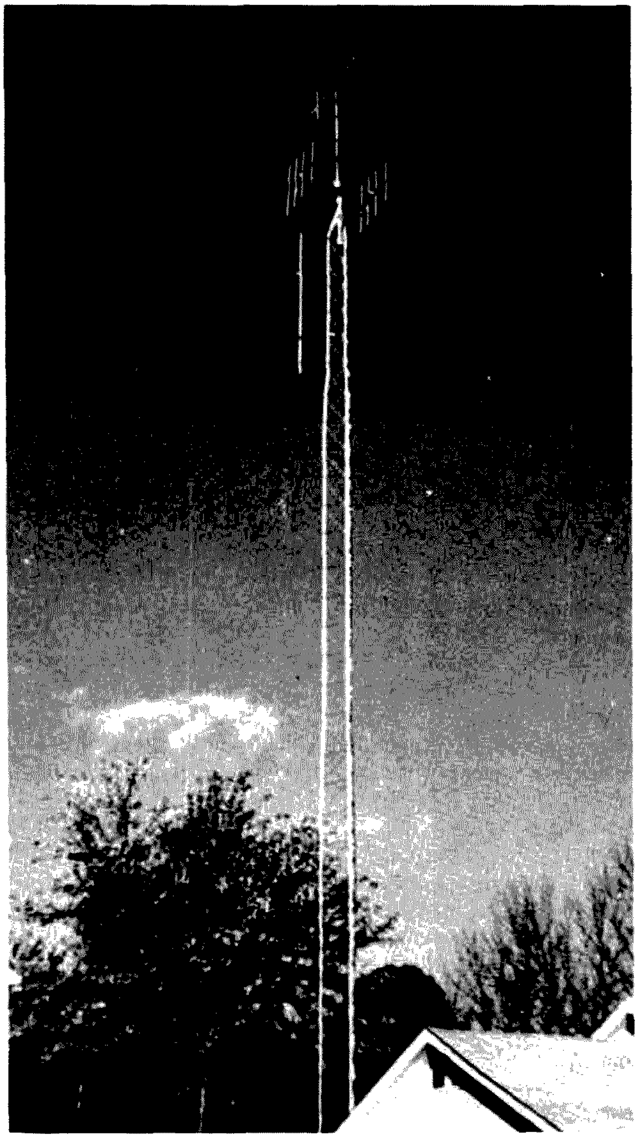
Weight of tower is uniform over entire length; 2. Weight of antennas, rotor, etc., is at top of tower; 3. No friction is involved anywhere.

In actuality, the tower seemed to weigh a great deal more. Despite the distinct advantages offered by the formula parameters "L1" and "H" – the rope being thrown over the house giving excellent elevation and fair distance from the tower base – the job proved to be a real doozy. Three robust amateurs – WB2COY, WB2CTH, and WB2HDS – were on the ropes while two other hefties – W2BEV and WA2QWP – walked the tower up. A double strand of 1/2 inch hemp proved barely sufficient – discovered, of course, about half way through the raising. Nevertheless, after much pushing, pulling, and puffing, up she went – vertical at last. With a sigh of relief, all broke into big smiles and exclamations of joy over a job well done.

BUT . . . but, all was not well. Murphy had other plans. Just a moment after the tower settled to the vertical position, a reflector element in one of the 2 meter beams slipped from its socket and fell to the ground. Luckily no one was injured, but after many hours of work this was

Fig. 1. Arrangement of rock anchors for securing rods.





The completed tower.

a most discouraging end to an otherwise fruitful day.

A few days later, upon recovering from the dropping reflector, WA2BXK climbed the tower and installed the offending rod. In the meantime, connectors were installed on the cables at the base of the tower and attached to the outside bulkhead. See photo.

As can be seen from the photo, all coax lines are fed through the side of the house via the bulkhead. The bulkhead consists of a piece of 1/8 x 2 1/2 x 5 inch aluminum plate with four double female "UHF" connectors. Type "N" would probably be better, but I could not find any locally. The interior surface of the outside bulkhead was coated with a cloth-like material similar to that which is used on water pipes to keep them from "sweating." There is a second such bulkhead on the inside wall. RG/8 jumpers between the wall connect the two bulkheads. The five-wire rotor cable is attached in a like manner, but standard male/female mike connectors are used.

Though such an arrangement contains numerous connectors, it has its distinct advantages. Should the tower have to be lowered, the cables can be easily disconnected/connected. Also, all lines can be quickly disconnected during thunderstorms. To complete the installation, both the tower and outside bulkhead are bonded together with No. 4 copper which is then run to ground – in my case, to a sixty-five foot well casing.

Finally, with all of the connections made, power was applied to the 2 meter antenna. And as you might guess, Murphy struck again. The initial swr was a horrible 2.25:1. To make a short story longer, the jumpers between the bulkheads proved to be the problem. Polyfoam RG/8 struck once more. Though there was "meter" continuity between the jumpers, not so for rf. Soldering the connectors to the coax caused minute bubbling of the foam which negated proper connection. A few more jumpers of regular RG/8, skillfully constructed by WA2BXK, and the problem was solved. The new swr was a respectable 1.38:1 over more than 1 1/2 MHz of the band. In conclusion, the antenna/tower project has proved very satisfactory. A northerly blockage with the old arrangement has been eliminated with the new tower. Direct 2 meter contacts with non-open (normal) band conditions have averaged more than 60 miles with full quieting reports. And, I can work all of the repeaters within the area – a radius of about 75 miles. Future plans call for a 15 meter beam and an 80 meter inverted "V". Many thanks to W2BEV, WZ2BXK, WB2COY, WB2CTH, WB2HDS, WA2HSF, WA2QWP, and W2VAQ as well as to WA1GFG/2 for the pictures. ■

The Speedy Audio Counter

- - good resolution without a long wait

The need for fast and accurate measurement of the low frequency tones in an electronic organ provided the basic drive to produce this counter. An earlier version was slightly less costly, but far too slow and lacked the needed resolution. This design works well, and should find acceptance with those wishing for precise measurements for most audio frequency applications.

Most electronic organs contain a master oscillator board that uses 12 slug-tuned coils for generating the highest tones, or the top octave. These are followed by a divider chain that provides successively lower octaves. It was decided to measure one of the lower octave ranges that spans from C6 at 1046.50 Hz to C5 at 523.25 Hz. With a conventional counter, a ten second gate would provide tenths of Hertz resolution at best, and a longer gate time is out of the question. The only reasonable approach is to count the number of higher frequency pulses that occur during one or more cycles of the frequency being measured. For example, if the number of one microsecond pulses were counted during one cycle of A5 at 880.00 Hz, you would get 1136. A ten cycle count gives 11363, and 100 cycles will read 113636. The period of one cycle of A5 is .00113636 seconds, so 100 cycles requires just over .1 second. You get the required resolution and fast update to the counter. To calculate the required display reading, just divide the reference frequency by the input frequency in Hertz.

A look at Fig. 4 shows that CMOS integrated circuits are used throughout. A four stage display counter consisting of 4026s count and decode to seven segments in decade fashion. These were used in preference to 4033s, as they have a display enable input that permits us to blank the display while resetting or counting. No latches are used as it was found a "blinking" display is actually easy to use. A new display means an updated count. 4049s are used with 680 Ohm resistors for segment drive to MAN-1 readouts. Three 4518s are used for the timebase divider to provide 100 kHz pulses, or .1 second and 1 second timebases. A 4518 is also used to divide the input to give x1, x10, and x100 ranges. Two sections of a 4001 are used for the crystal oscillator and buffer, and two sections of another 4001 comprise the input amplifier. The input amplifier is biased slightly above or below the threshold point to prevent random triggering. A 4013 and three sections of 4001 are used to provide synchronization and division of the input, reset, display gating, and clock pulses to the counter chain. This gating system requires a minimum of parts, yet provides a 50/50 gate and display cycle. The reset is one-half cycle of the reference frequency that immediately precedes the count. As the 4026s require less than .5 usec for reset, it may be possible to use a higher reference frequency.

A two section, 6 position switch permits switching between the two count modes. Position A gives a direct reading in Hertz per second. Position B gates for .1 second. These two scales give a positive reference for gross tuning adjustments or quick identification of an unknown frequency.

Switch position C provides pulses at a 100k rate and D at a 1 microsecond rate. Positions E and F bring in the input

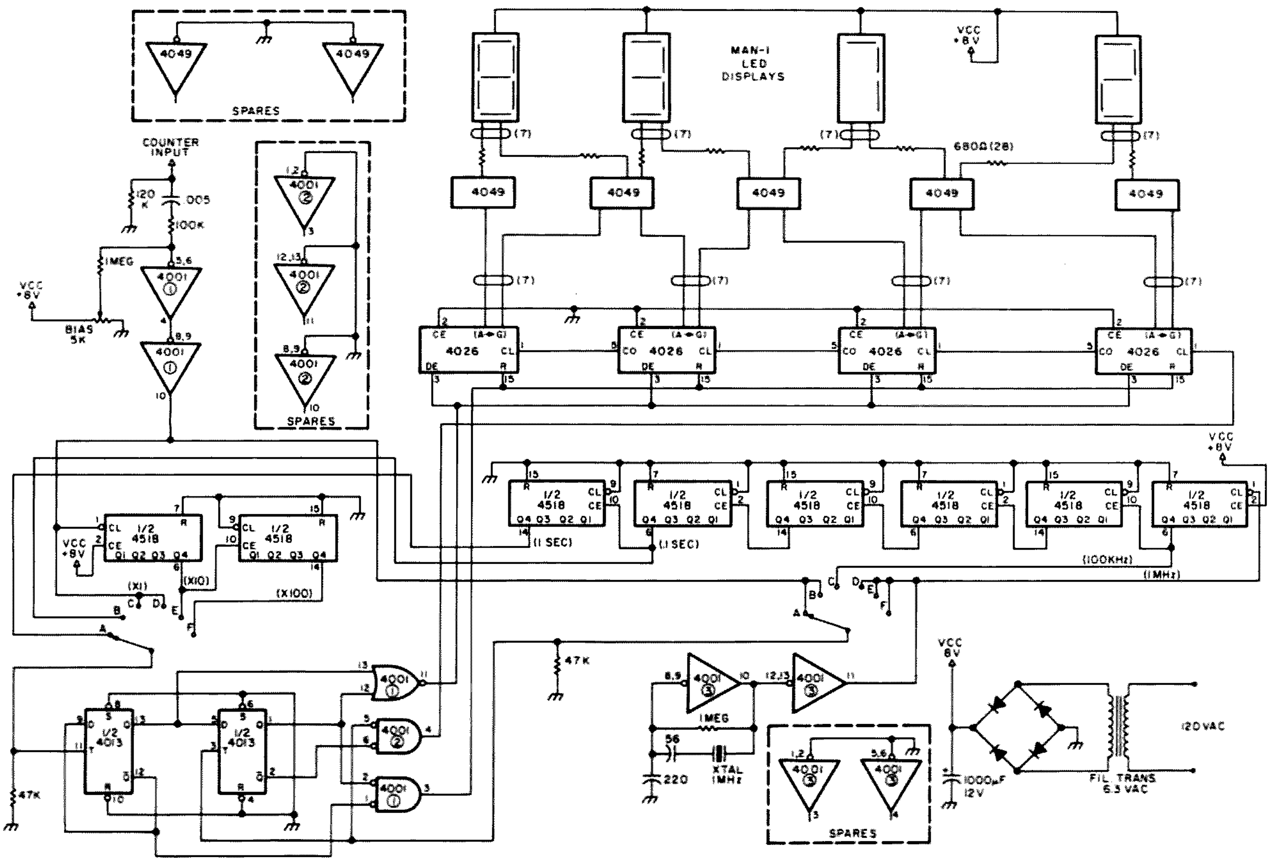

Fig. 4.

divider to give an effective x10 and x100 in resolution. An example of expected readings of A5 at 880.00 Hz would be: A – 0880, B – 0088, C – 0113, D – 1136, E – 1363 and F – 3636. The more significant digits drop off on the higher resolution scales, but it was felt that an overflow indication was not needed.

Construction was on a piece of perfboard with holes spaced .1 inch, mounted under the top cover of an existing function generator. The cabinet measured 7" wide, 5" deep and 3" high. The perfboard was slightly smaller with a section removed to permit the switch and input jack to be mounted on the top. The LEDs, ICs, and resistors were mounted on the top of the board, and point-to-point wiring used for connecting the components. The power supply is mounted on one end of the box. The crystal, originally from a BC-221 frequency meter, was removed from the metal cover and mounted on the board. If you have enough room in your cabinet, it would be better to leave it as is, and mount it with a clip or octal socket. A slot was cut out to reveal the LEDs and covered with plastic laminate for protection. A switch position scale and a chart of frequencies and their respective periods were typed up and pasted to the top, covered with more of the plastic laminate.

Sketches showing the general construction of the unit, and general layout of the circuit board are shown. A much more compact unit could have been constructed using printed circuit techniques, a two piece double-deck board, and substituting MAN-3 readouts which are smaller and would not require the 4049 segment drivers and resistors.■

Versatility Plus for the HW-202

-- extra channel mod

The HW-202 is a fine piece of 2 meter equipment, but six crystal pairs tend to limit the operation during travel periods. In any case, I could use a minimum of nine pairs. Six would be local repeaters and direct channels; three would be out of state or repeaters that are used during vacation, etc. I originally had the tone burst assembly installed in the HW-202, but the touchtone pad gives me all the inputs I need. Therefore, there is a nice space to put in a module the same size as the tone burst assembly, using the present mounting holes and front panel component holes. The switch module can also provide inputs for a synthesizer.

Circuit Description

Fig. 1 shows the circuit and it can be seen that it is a repetition of the circuits in the HW-202 except the inductive trimmers for the receive crystals have been left out. It was found that 90% of the receive crystals tuned at the same slug position.

The circuit shows seven crystal pairs and one switch position for synthesizer inputs. It is possible that additional crystals could be added because there is some space left on the board. There are three connections to be made to the transceiver circuits: receive crystal switch S1A to Y102 pin toward front of unit, transmit crystal switch S1B to Y202 pin toward left side of unit, and synthesizer key to pin 2 of mike jack. The circuit ground is accomplished by the mounting hardware in most cases. A wire ground can be made from bus shown on Fig. 2 to the lug on the speaker of the HW-202. These connection points are shown on a schematic on page 133 and circuit boards on pages 128 and 130 in the Heath Assembly Manual. Although Fig. 1 shows a 2 pole switch, a 4 pole, 4 section switch was installed so that if the crystals were excited during synthesizer operation, the extra two poles could be used to short out the crystal circuits.

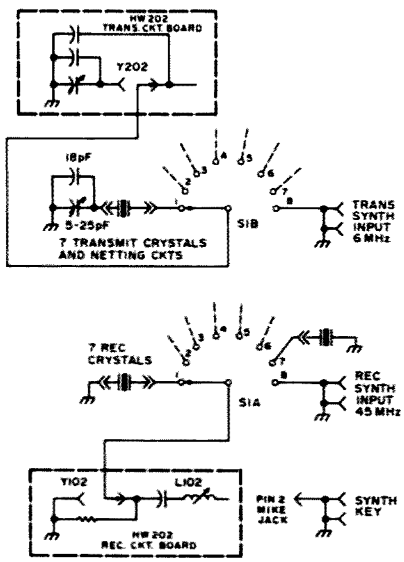

Fig. 1. Schematic of added crystal deck.

The synthesizer inputs were included to make the circuit more useful. The transmit synthesizer input (T) could be used for an outboard crystal and easily adjustable netting trimmer in a small box. The receive synthesizer input (R) could be used for a vco or vfo input. The synthesizer key (K) is to energize the transmit vco by way of a relay.

Mechanical

The module is built on 1/16" thick perforated board with .1 x .1 hole pattern. The mounting angle is made from 1/32" thick aluminum and can be bent very easily in a vise. This can be attached to the perforated board with brass rivets, eyelets or screws. Fig. 2 shows the assembly. The major dimensions are shown, as are general positions of components. All connections on the rear must be kept flush against the board or it will not fit in the HW-202. The miniature tube socket contacts or equivalent are pushed through the drilled holes and the tails bent flat against the board. Dummy crystals or substitutes must be plugged into the crystal contacts and all soldering done. The copper strip or bus ground will hold some of the components in place once it is soldered in place. Miniature crystal sockets could be used in place of the contacts shown, but must not protrude below the board more than 1/32 inch or make the height of the mounted crystal more than 5/8" above the board. The trimmer capacitors are also pushed through the drilled holes and the tails bent flush against the board. All wiring on the board was done with insulated no. 30 wire. The leads attached to the Heath circuit were no. 26. After all the soldering is done on the rear of the board, the component tabs, wire, and ground strip should be covered with Hysol Epoxy-Patch 0151 clear or equivalent, which will hold everything in place.

The wiring from the switch is routed near the crystals' top side, and then down through a convenient hole to the proper tail on crystal connector.

The front panel switch plate may be cut out and cemented to a 7/8" x 3-1/8" plate with 1/8" and 1/4" diameter holes for the switch and connectors. A thin plastic film should be laid over this for protection. Another way of fabrication is to make a clear film negative of the photo and apply to the plate using double faced clear tape. The surface of the aluminum plate should be brushed horizontally with sandpaper

previous to putting the film on for good appearance.

Installation

The disassembly instructions for the HWA-202-2 tone burst encoder on page 12 of the assembly manual should be accomplished. The crystal module can be attached in the same manner as the encoder, but use 4-40 flat head screws and standard lock washers and nuts. A thin piece of insulation should be placed between the crystal push-button assembly and the new module to prevent any shorts.

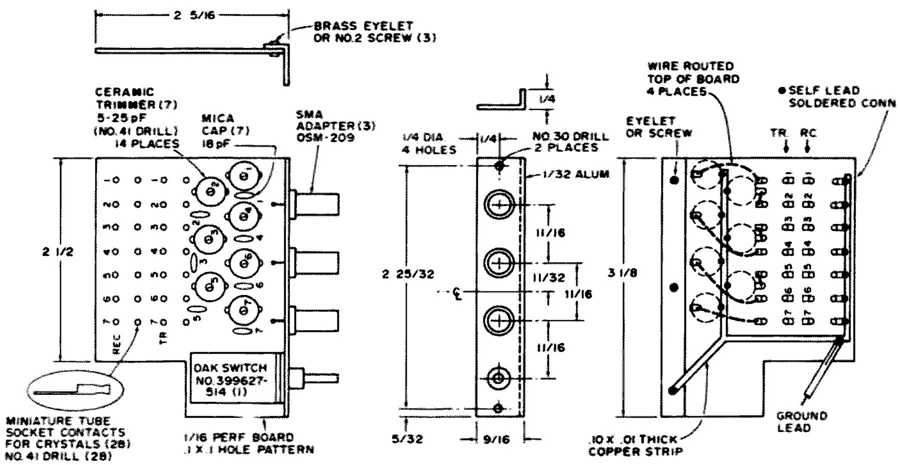

Fig. 2. Added crystal deck assembly for HW-202.

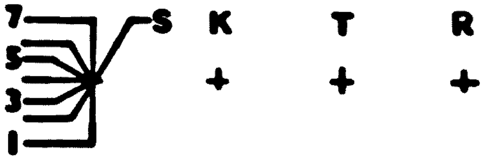
Adjustments

The receive crystal inductor L102 should be adjusted to average reception of all receive crystals in the new switch module. In my case, all crystals were very near, making an average setting easily accomplished. The transmit crystal trimmers will have to be adjusted using a counter or in the same manner as the other transmit crystals were trimmed.

Conclusions

No trouble was encountered in the operation of the switch module. The additional crystal pairs made the Heath 202 much more useful as traveling equipment. Since the space on the front panel is limited, a switch knob that can be turned in the allocated space must be used. The knob must not be more than 1/2 inch diameter and at least 5/8 inch high. This allows a firm grip with two fingers. ■



Switch plate for front panel.

The Boomless Microbeam

-- works better than it ought to

Many methods have been tried to fold, load and twist the elements of 20, 15 and 10 meter beams to make them more compact while still retaining reasonable performance. No one can or should expect a compacted beam to work as well as a full size beam. Working "well" refers to forward gain, front to back ratio, low loss and low swr over a reasonable bandwidth. Designs have been made which optimize one factor at the sacrifice of all others. For instance, a beam might be determined and loaded to produce a low swr over an entire band, but usable gain might occur over only a very narrow portion of the band. Such a beam design might look good in advertising literature — "broadband, low swr, moderate gain" — but it really doesn't deliver much. On the other hand, not many amateurs would buy the beam if it stated "very low swr and high gain over any selected 50 kHz portion of a band."

Whether it is worthwhile to go after a compact beam (either commercial or home brew) for a few extra dB obviously revolves around the cost and effort involved. Sometimes the few extra dB aren't as important as adding some directivity to the antenna system to improve the reception side of things. This sort of evaluation has to be made for specific circumstances. But, one can't make it without good details on what one is building or buying.

The boomless 2 element beam described in this article is not a cure for all problems, although variations of this design have successfully been used for over 10 years by various amateurs. Rather than make sharp compromises in any one direction, the main advantage of the design is that it makes moderate, acceptable compromises in several directions. It has a gain of several dB across a given band, the swr is low (2:1 or less) across a band, and the front to back ratio is a usable 10-15 dB across a band. Also, and perhaps most importantly, it is simple to construct. The electrical layout of the beam is shown in Fig. 1. It consists of a driven element and a director element. A reflector element for the parasitic element might produce somewhat more gain. But at the close element spacing used, a director element has only about 1 dB less gain and produces much better overall front-to-back ratio properties. The beam dimensions are as shown for 20 meters and can be scaled down or up for other bands. The dimensions have been arrived at empirically by those who have built this type of beam and seem to yield the best overall average results. Because of the loading effect produced by folding back the elements, their overall lineal length is greater than that found in full size beams, although overall the beam is much more compact than a full size beam.

The driven element is not shown separated for connec-

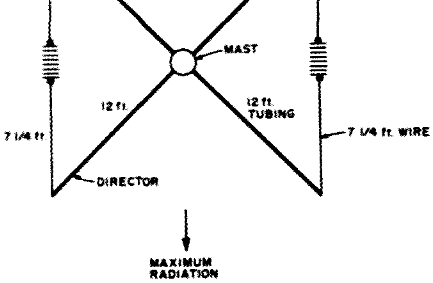

Fig. 1. Basic beam dimensions for 20 meters.

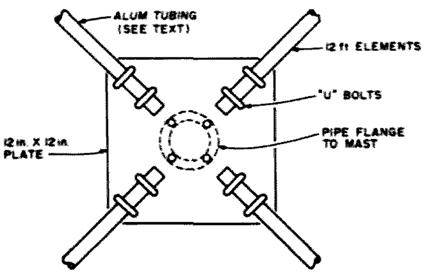

Fig. 2. Mast mounting plate.

tion to a transmission line. It could be separated in the center and fed directly, preferably through a 1:1 balun, with 50 Ohm coaxial line. The match should be a good one, producing a low swr without any matching devices. The director element is left as shown.

Feeding the antenna in the preceding manner requires, however, that the two sides of the driven element coming towards the mast be insulated from the mast. Simplified plumber's delight construction can be achieved by having all of the antenna elements coming towards the mast grounded to the mast and the driven element feed via a gamma match. Various construction techniques can be used for the purpose depending on the tools and equipment available. Fig. 2 shows one simple method which does not require any special tools. An approximate 12 by 12 inch aluminum or steel plate is used with a pipe flange which fits over the mast. Of course, it would be best if a steel threaded mast could be used. The antenna elements are nested aluminum tubing starting with 8 foot lengths of 1¼" OD aluminum. These are secured to the square mast plate by means of two U bolts on each element. The total length of 12 feet for each element is made by nesting 4 foot tubing into the 8 foot sections. Tubing clamps are used to secure the sections together. Alternatively, the 12 foot elements of aluminum are locally available. The rest of the antenna is made of #12 wire strung between the tips of the 12 foot sections. Nylon clothesline (the type without metal reinforcement) makes a good, simple insulator between the wire sections.

There is no tuning to the antenna other than matching the transmission line to the driven element. One could experiment with tuning of the driven and director elements by varying the length of the wire sections of each element, but it is doubtful if any better performance would be achieved. Transmission line matching is done most easily with a gamma match as shown in Fig. 3. A 55" length of ½" aluminum tubing is run parallel to one 12 foot leg of the driven element at 3-6 inch spacing. It is supported at one end by a metal shorting clamp to the driven element, and at the other by the housing of a plastic box which contains a series 200 pF variable. The plastic box is mounted on the bottom of the mast plate and can be supported by the U clamps which hold the 12 foot elements down. A sturdy plastic kitchen food container can be used for the enclosure where severe weather is not a problem. Otherwise, a solid plexiglas housing is needed. The metal shorting clamp is moved along the driven element a few inches at a time and the variable capacitor tuned for each setting until the lowest swr is achieved on the line. The beam should be in its final operating position or as high off the ground as practical while making this adjustment.

Any medium to heavy duty TV type rotator will suffice to handle the beam antenna. ■

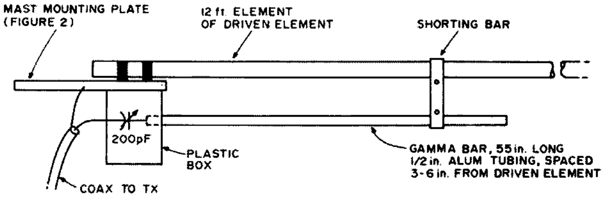

Fig. 3. Gamma match to coaxial transmission line. The gamma bar can be placed on either of the two 12' driven element members shown in Fig. 1.

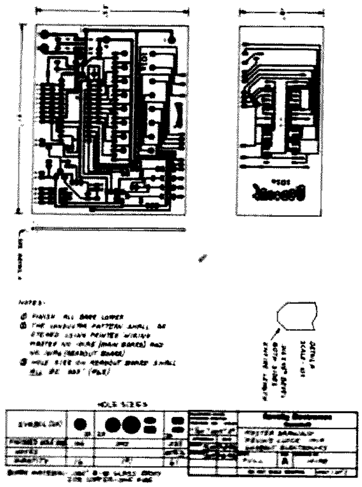
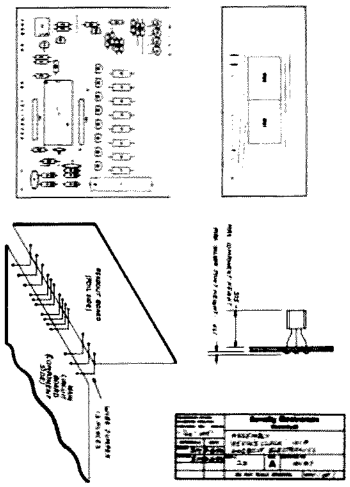
Making Your Own PC Boards

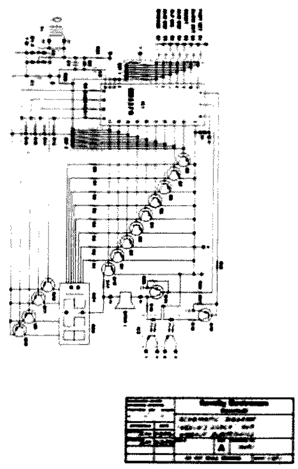
-- part I

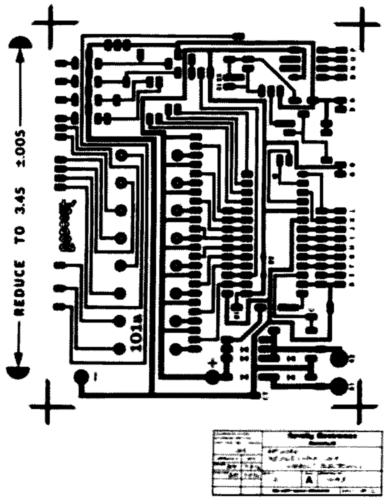
There have been quite a few construction projects in magazines lately, some without printed circuit board artwork. Oftentimes, with a simple project, a PC board is unnecessary. However, when a project starts using a lot of components and gets complex, it is usually much easier to use a board. This does not apply only to magazine projects. Home brew ideas will have a neater, more professional look if a circuit board is used.

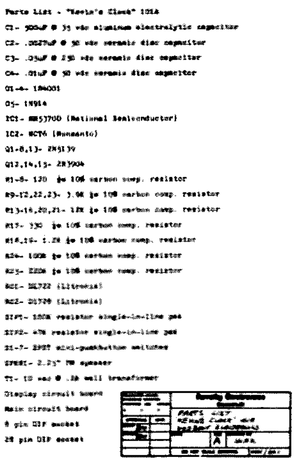
This is the first of a two part article dealing with the design and manufacture of printed circuit boards. It will

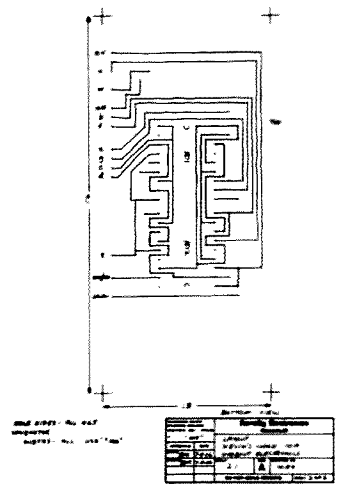


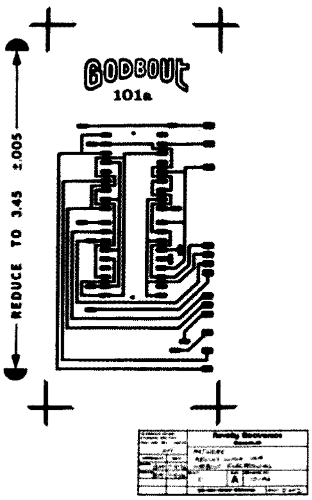


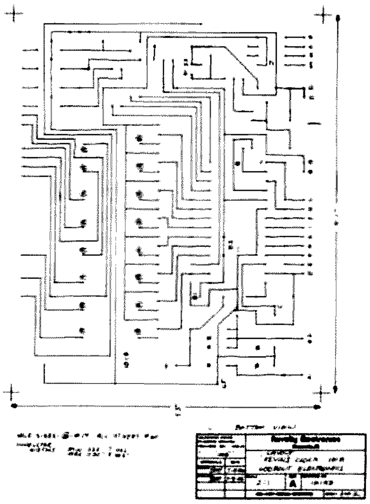












cover everything necessary for the home experimenter to produce high quality, professional-looking boards. This part of the article will deal with documentation and production of artwork for a single-sided board. Next month we will cover double-sided boards and the manufacturing process.

While the use of a printed circuit board is generally a good idea, there are times when a second thought is advisable. As with any good thing, a PC board has its disadvantages. Some arguments for and against the use of printed circuit boards are as follows:

PROS:

1. Weight reduction as much as 10 to 1.
2. Designed in performance.
3. Ease of inspection.
4. Diagnostic analysis and troubleshooting simplified.
5. Positive and straightforward parts identification.
6. Space organization and control.

CONS:

1. Volume inefficiency, space utilization poor (essentially two plane).
2. Poor repairability.
3. Conductors may be exposed, causing insulation degradation or even possible shorting.
4. Thermal design complicated and limited.
5. Design regimentation and restriction, with electrical and mechanical compromises.
6. Circuit revision dif-

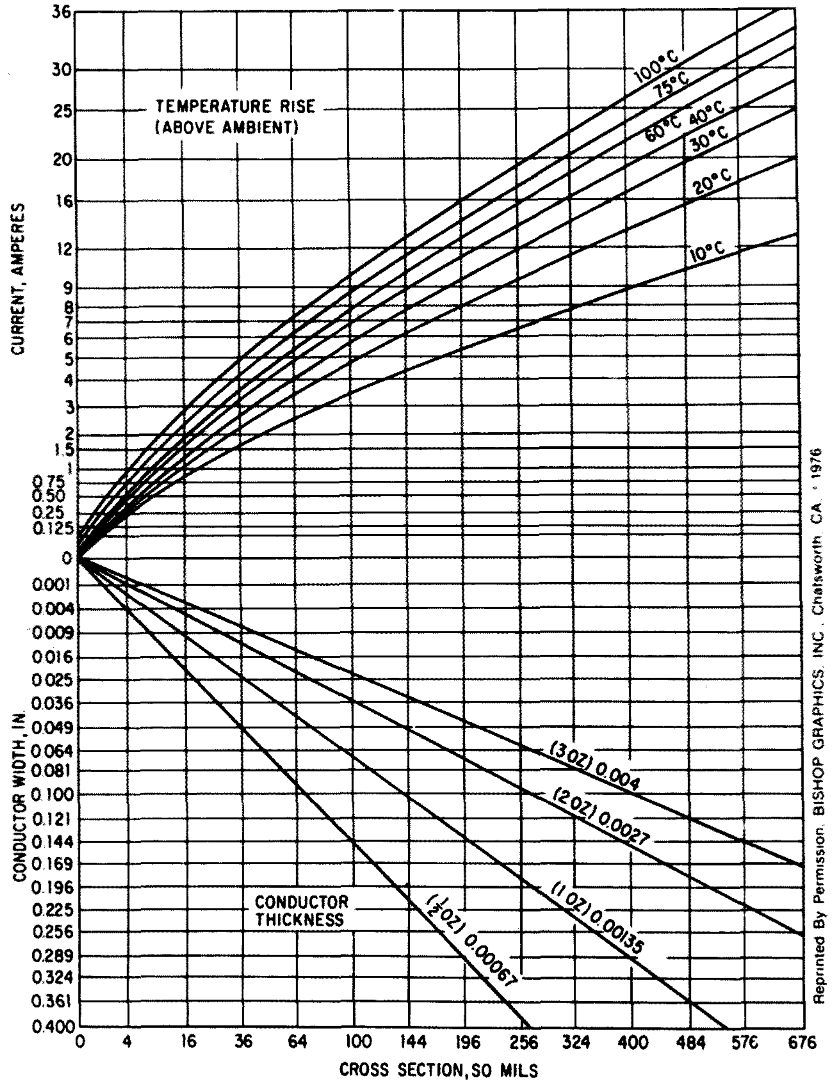


Fig. 3. Use this chart to find minimum conductor widths for the circuit board.

ficult and sometimes impossible.

Single-Sided or Double-Sided?

When you do decide to use a circuit board, you should be aware of what is available. Currently, there are four different types of printed circuit boards you can use. These are single-sided, double-sided, multi-layer, and flexible. The single-sided board has all of the wiring on one side, with the components on the other side. The laminate serves as an insulator and support. The double-sided PC board has the bulk of the wiring on the bottom, with the remainder on the top side. Components are generally mounted on the side with the least amount of wiring.

A multi-layer board is composed of many very thin boards laminated together. Sometimes as many as 19 individual layers may be found in one multi-layer board. The home manufacture of this type of board will be discussed along with double-sided boards next month.

The last type of board in common use today is the flexible circuit. Very simply, this is a single- or double-sided board using a paper thin laminate. An example of their common usage can be found in the dash of many newer automobiles.

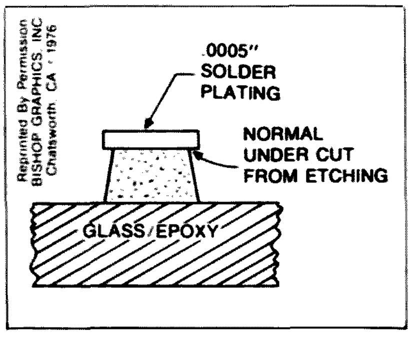

Fig. 4. Conductor edge undercut.

With a selection like that to choose from, which type of board do you pick for a particular application? Choosing is really very simple. Multi-layer and flexible circuits are the most difficult for the home experimenter to manufacture, so they are out. We are left with a choice between single-sided and double-sided boards. Single-sided is the least expensive, but can be a headache to design if the circuit is complicated. Double-sided boards offer more flexibility in design, but are a bit more expensive.

Look at the circuit you are going to design a board for. Is it complex? Does it use a lot of integrated circuits? If your answer is yes, you may want to use a double-sided board. If your circuitry is fairly simple and/or straightforward, you may want to use a single-sided PC board. This month we are going to design a single-sided PC board for the digital clock in Fig. 1.

Documentation

When you have decided to make a printed circuit board, the first thing to check is whether you have adequate documentation. This would be a schematic or logic diagram, a parts list, and any other pertinent data. This step is important, whether you are going to make a one-of-a-kind prototype or a production run of a few hundred or more. Good documentation helps prevent mistakes that may occur later in manufacturing. An example of documentation is shown in Fig. 2.

When drawing your diagrams, there are some points to remember. Signal flow should be drawn from the left to the right, with the inputs on the left, the outputs on the right. The highest voltage potentials are normally drawn toward the top, the lowest

Table 1. Conductor spacing.

toward the bottom. Support circuitry is drawn on the lower half of the drawing. These are oscillators, power supplies, and other circuits not included in the main drawing. An exception to this rule is when it is easier to include a support circuit in the main diagram.

It is not necessary to follow these rules. However, most drawings tend to follow them, and standardization helps reduce possible confusion and problems later on.

When drawing a schematic diagram, it is a good idea to draw it in such a way as to keep crossovers to a minimum. This drawing is what you will be using to lay out your board. Crossovers on a PC board represent electrical connections. This will become more clearly understood when the layout has begun. A typical schematic diagram for a four digit digital clock is shown in Fig. 1.

Layout Design

The printed circuit board layout is the necessary step between the schematic or logic diagram and the master artwork. It should contain all of the circuit board design information. The component locations, interconnecting circuitry, and board outline should all be included, drawn to scale. The scale used, hole and conductor sizes, as well as all measurements, should be noted external to the board area.

The use of a grid system when doing a board layout is important. Most electronic parts are spaced on a 1/10" grid.

A grid is a "two-dimensional rectangular network consisting of a set of equidistant parallel lines superimposed upon another set of equidistant parallel lines with one set of lines perpendicular to the other." (Bishop Graphics) The most common grids, at actual board size, in use today are .100", .050", and .025" in order of preference.

All board artwork and layouts should be done at an enlarged scale. Errors in pad and conductor alignment and imperfections in drafting aids will be reduced proportionately with the reduction of artwork to finished board size.

The scales most often used for layouts are 2x, 4x, and 1x, in order of preference. 1x should always be avoided except in cases where reducing facilities are not available.

When designing a PC board, careful thought must be given to conductor width and spacing. If a conductor is too small, discontinuity may result. On the finished board, consideration must be given to possible heat problems. Narrow traces will lift off very easily. Their added difficulty in manufacturing will result in an increased cost. Narrow spacing is also difficult to manufacture and may cause short circuits. Widths and spacings that are too large may result in wasted valuable board space.

Conductors larger than .500" should be avoided. If larger conductive areas are needed, as in the case of ground planes, they should be relieved to avoid blistering or warping during soldering. More information on ground planes will be discussed later.

Conductor width should be determined by the required current carrying capacity. Width may be selected by referring to Fig. 3. Spacing is determined by the voltage present, and whether the board has been coated or not. If narrow spacing is used around high voltage, arcing may result. Table 1 shows suggested conductor spacing determined by voltages present. Typical spacing of .031" or .050" is suggested for low

Table 2. Pad sizes. Note: All measurements shown in inches.

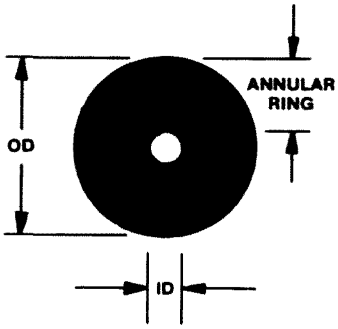

Fig. 5. Annular ring in detail.

voltage applications when space permits. Conductors should be placed no closer than .100" to .250" to a board edge or mounting hardware.

When the PC board is etched, a small amount of copper will be removed from underneath the resist or plating. This should be taken into account when selecting a conductor width or pad size. With larger conductors, this undercutting can be considered irrelevant. However, when using narrow conductors (approximately .015" and smaller), if great precision is required, add one or two thousandths to allow for this. See Fig. 4.

Pad Sizes

Choosing pad sizes is much the same as choosing conductor widths. Instead of width, however, we have what is called annular ring to think about. Annular ring is (OD-ID)/2, where OD is the pad outside diameter and ID is the hole size. See Fig. 5.

There should be a separate pad and hole for each component lead or connecting wires. Hole exceptions are made for components in a "flat-pak" configuration.

Pads should be as large as practical while maintaining minimum spacing requirements. Table 2 lists suggested pad sizes for common components.

Oftentimes mounting holes as well as component leads will have pads. When using a pad for a mounting hole, make the pad as large or larger than the screws or washer that will contact the board. In this way, when taping up the master artwork, you will have a better knowledge of where nearby conductors may be placed.

A ground plane is an area of the circuit board used as a common point between many connections. This is usually the ground of the power supply, hence its name. Rather than being a narrow conductor from one point to another, a ground plane is a large area of copper. These are often used as supply buses or shielding, especially in high frequency circuits. Ground planes are sometimes used for heat sinking, although their use for this application is somewhat limited.

When laying out a ground plane, approximately fifty percent should be relieved to prevent blistering and a heat sinking effect during soldering operations. Fig. 6 illustrates two common methods of relieving the copper. An exception to this rule could be when the ground plane is designed to be a heat sink. Under these circumstances, the idea is to have as much copper exposed as possible.

For connections to the ground plane, special pads are suggested. These are detailed in Fig. 7. A clearance is provided between the terminal area and ground plane. Where continuity is desired between the pad and the ground plane, two to four connections are made. This helps prevent a poor solder connection resulting from the heat sinking problems discussed earlier.

Special Considerations

Designing a circuit board is not always as easy as it may sound. Very often, a circuit will have many special problems to consider. Feedback, noise popping up where it should not, and uneven propagation delays in digital circuits are only a few of the many unexpected problems that may occur in the finished product if the board is not designed with thought. Conductor routing on a PC board is basically the same as wiring a circuit point to point. The same care must be taken when designing a PC board.

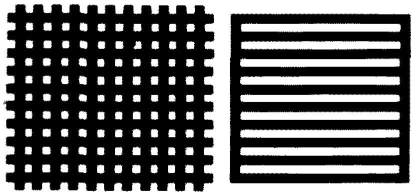

Fig. 6. Methods of relieving copper for ground planes.

When a board is designed and feedback could be a problem, you can run a ground line between the sensitive section and the area most likely to cause interference. Fig. 8 illustrates this with a few typical problems. Some other problems to watch for are high voltages, currents, or frequencies. Heat distribution may also create a headache. Be sure that heat sensitive parts are kept away from power devices.

When drawing a layout, it should be drawn looking at the bottom of the board — that is, from the foil side. This can become confusing at times, but there is a good reason. The master artwork is copied directly from the layout. When the artwork is photographed, you will want a negative with the emulsion side facing the board. The exception is when the board is to be silk screened.

As bad as this may sound, doing a layout in this manner is not really hard. All you have to remember is that everything is drawn upside down. After a while, drawing like this will become second nature.

To do a layout, you are going to need the following materials: some tenth inch graph paper, black and red pencils, and an eraser.

The graph paper should be a precision type, printed on stable material for accuracy. If the board you are going to make does not require extreme precision, any tenth inch graph paper will do.

Layout Design Techniques

Before beginning your layout, find an area in the schematic where a group of components share a common point. Draw these parts on the grid by drawing a dot where each lead will go. To avoid confusion later, the symbol or part number is drawn where the component will go. Once you have the parts drawn in, draw the interconnecting lines between the dots (pads). If the schematic diagram has been

Fig. 7. Special pads for ground planes.

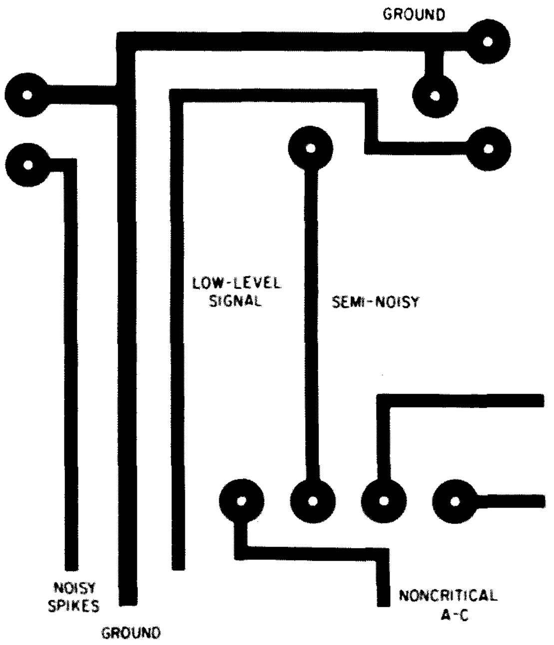

Fig. 8. Typical layout problems and solutions.

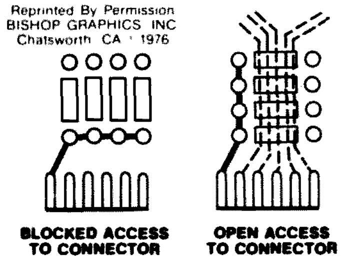

Fig. 9. Arranging parts to provide maximum access to other components or edge connectors.

drawn with as few crossovers as possible, this step will be very easy. Places where crossovers exist on the schematic may be remedied by remembering that conductors may be placed under parts and between pads. An alternate but very similar method is to lay out the board basically the same as the schematic has been drawn.

Other methods of layout design include choosing one or more multi-lead components and radiating outward from them. This is what was done with the four digit clock in Fig. 2. When using a connector, or pads for external wiring (inputs, outputs, or external parts), locate these pads first. Sometimes it is easier to do this and radiate components inward.

When laying out a board, care should be taken to keep a neat and orderly appearance. Components should be positioned to provide maximum access to other parts. See Fig. 9.

On a single-sided board, it is possible, and very likely if the circuit is complex, that you will have a crossover or two. Maybe even a few more. However, crossovers on a circuit board represent short circuits and so are not allowed. To remedy the crossover situation, we use jumpers. A jumper is a wire placed on the component side of the board to "jump" over conductors on the bottom. These should be treated as separate components. That is, they occupy space and need two holes. When a jumper is drawn on the layout, use a different color pencil to indicate placement. This helps prevent putting parts under or over a jumper wire.

After the layout is finished, carefully check it over for mistakes. Accuracy here is very important. The master artwork, and hence the board, will reflect everything on the layout. Unless you are in a hurry, it is sometimes best to let the layout sit overnight before checking it. It is surprising how many times you may overlook a mistake.

To elaborate further on layout design, I will use Fig. 10 as an example. This layout

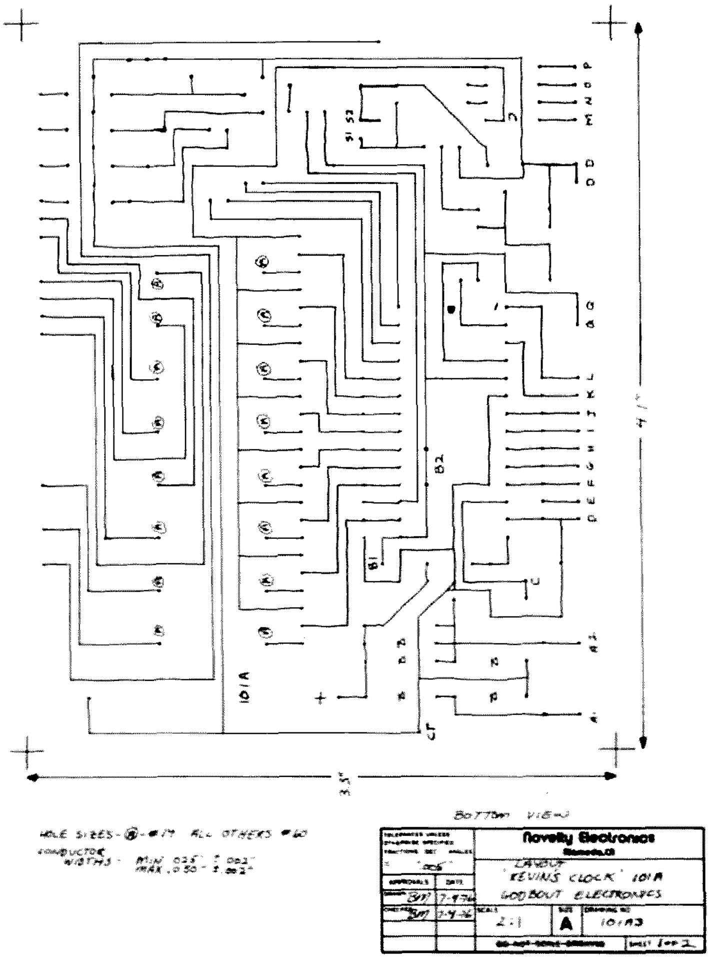

Fig. 10. Finished "main board" layout for the clock.

was drawn from the schematic diagram in Fig. 1.

Briefly, here are the steps that were taken. IC1 is the main component and also the one with the most connections. Very conveniently, the switch inputs are all on one side. This helped decide its position and placement. Pull down resistor packs SIP1 and SIP2 were placed directly opposite the segment and digit enable outputs. (The guys who decided the IC pinout sure did a nice job.) The next things to lay out were the segment enable transistors and limiting resistors. The distance the transistors were placed from SIP2 was calculated figuring the use of .050" tape (.025" conductors on the finished board). Four conductors would have to be run parallel to the IC. I counted up two tenths from SIP2 and drew my first line. Using the tenth inch graph paper as my guide, I drew three more lines one tenth inch apart. This gave me .025" conductors with .025" spaces on the finished board. Allowing two tenths again for spacing between conductors and pads, I now had the spacing needed between the SIP and the transistors. With this in mind, I centered the transistors above the SIP .350" away from it. Unless otherwise noted, by the way, these figures are layout size (2x) rather than actual board size. The rest of the segment enable parts should be self-explanatory.

Digit enable was a bit more difficult. I knew approximately where the board edge was going to be, so I worked backwards from there. The transistors were set up kind of funny because I did not want to cut or use narrow pads. This clock was designed for a kit, and large pads make it easier to assemble. I also did not want to use any jumpers here. Anyway, if you look closely at the layout, you can see basically what I did. I just worked downward, placing pull down resistors where needed as I went. After these, I put the series resistors in using the same method.

The power supply was fairly straightforward, and should not need any explanation. Perhaps the most difficult was the section with the optoisolator (IC2). Basically, I just put the parts where they would fit. The optoisolator fit conveniently in the corner. It also has four outputs that I wanted at that edge. The rest of the circuitry in this section can be best explained by careful examination of the layout. The readout board will not be explained here because of its relative simplicity.

Artwork Pattern Configurations

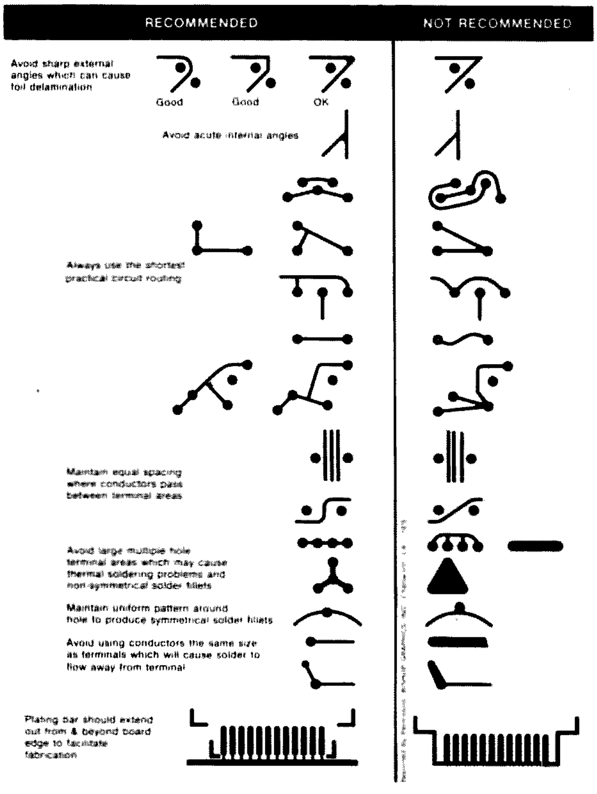

Fig. 11. Dos and don'ts for taping artwork.

Artwork Design Techniques

Before you begin taping the artwork, familiarize yourself with the different methods available. These include pen and ink, "rub-ons," drafting tape and preprinted "stick-ons."

With the pen and ink method, everything is drawn by hand on drafting vellum or directly on the blank board. This method is unreliable and produces inferior quality artwork. Therefore, its use is not recommended.

Rub-ons are symbols with gummed backing preprinted on a plastic base material. These are used by positioning the symbol over the area desired and rubbing the backing with a blunt instrument until the symbol comes off. This method is usually used on a blank board. Results are sometimes impressive, but you end up with a one-of-a-kind board. A problem common to rub-ons, however, is cracking. This produces broken conductors, split pads, and the like.

The last and by far the best method is using tape and preprinted stick-ons. This is the most common, and produces the best looking boards in the end. Stick-ons may be purchased in a large variety of configurations, with patterns available for almost all types of electronic components.

Using this method, die cut pads and stick-ons are positioned on mylar in positions dictated by the layout. Connections between components are made with precision slit artwork tape. This tape comes in standard widths from .015" to 6" ±.002" in both metric and decimal sizes. Preprinted stick-ons are also manufactured to a tolerance of ±.002".

With everything else out of the way, it is time to tape up the artwork. You are going to need artwork materials: tape and stick-ons as mentioned earlier, a razor blade or X-acto knife to cut the tape, and some drafting film. The easiest to use is mylar with a matte finish on one side. All of these things are available from Bishop Graphics in Chatsworth CA. A light table will make it easier to lay out the artwork, but it is not absolutely necessary.

There are two ways to do artwork. One is with straight lines and sharp corners. The other way has curved lines and corners. The only problem with this method is that the draftsman must be somewhat artistic. If he is not, it is possible to end up with messy-looking artwork. Using the square corner method is preferred, but it does have a drawback. When etching, you have to watch out for undercutting at the corners, though careful planning and design can take care of this.

Now you are ready to start. Finish off that cup of coffee you have been drinking, and go wash your hands. Soft drinks and food are also forbidden while taping the artwork. Believe me, the last thing you want to do is accidentally spill something on half-finished artwork. The reason for clean hands should be obvious. Fingerprints and smudges can also help ruin otherwise good artwork.

The easiest way to produce artwork is to place the layout directly underneath the mylar and tape directly over it. Another way is to

place a piece of precision graph paper under the mylar and transfer the pattern from the layout to the mylar by way of the drafting aids. This way takes considerably more time, but is the cheapest if you want or need precision. Doing layouts using individual pieces of precision graph paper could get expensive after awhile.

To apply the stick-ons, slip the knife or razor blade under one edge of the stick-on. Lift carefully until it is fully off. Position the pattern over the mylar and press down gently with a finger. For larger patterns (DIPs, connector strips), use the knife to hold one side of the pattern, and a finger to hold the other. Place the pattern in position and apply light pressure. Applying only light pressure to secure patterns in place allows you to easily remove and reposition them if needed. Die cut pads can also be applied in the same manner.

Tape is applied by placing the end of the roll over the center of a pad and applying pressure to hold it in place. Then take and run the tape down to the terminating area, applying light pressure all the way. Be careful not to stretch the tape as you go, to avoid "creeping" later on. When cutting off the ends of the tape, it is best not to "cut" the tape, as this may cause a scratch or a blemish the camera will pick up later. Instead, hold the knife, edge firmly against the width of the tape. Using the other hand, pull the tape up at an angle away from the blade. This method assures a clean cut without mangling the rest of the artwork. When cutting tape at a corner, be sure to get it all. Do not let any excess hang over, preventing a nice sharp corner. Fig. 11 illustrates some dos and don'ts for artwork pattern configurations. Fig. 12 shows the finished artwork for the clock.

To mark off the edges of the board, delineation marks are available, or you can use two pieces of tape placed perpendicular to each other.

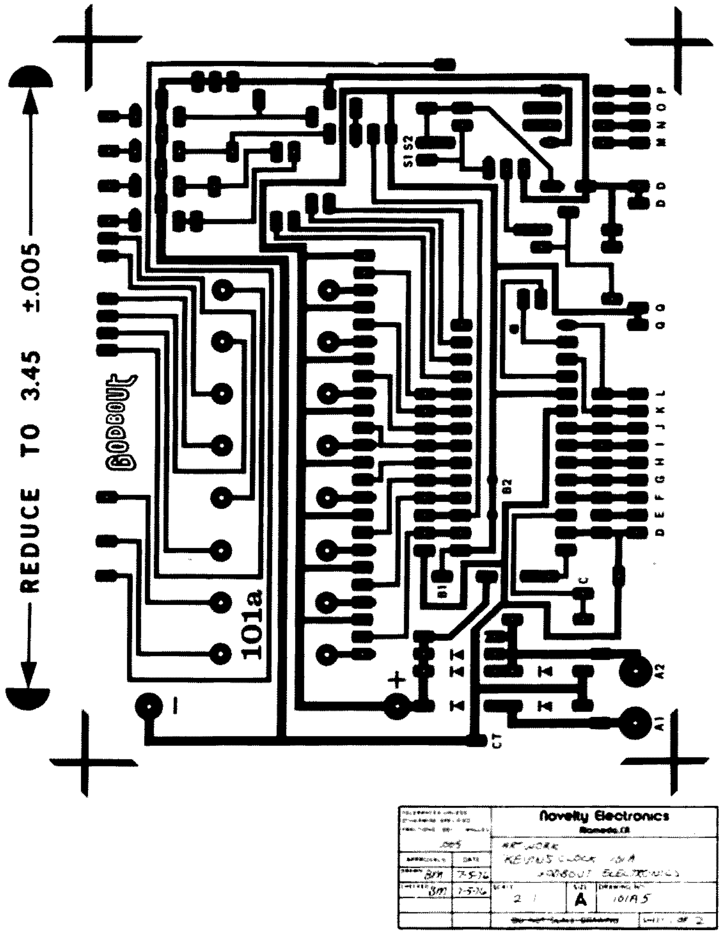

Fig. 12. Finished "main board" artwork for the clock.

When you are all finished with the artwork, check it and compare it with the layout. This is the most important step of all. Bad artwork will cause bad boards, which in turn will cause a product that does not work. Now is the time to double check and make sure this does not happen.

So now you have finished artwork and want to make a board? You are going to have to have a negative made of your artwork. Do not use a 35mm or similar type camera. Results are poor and it is not worth it. Find someone with a camera designed for copying line or halftone material. (Line material is straight black and white with no shades of gray in between. Halftones are used for photographs. A magazine photo is a halftone.) The type of camera you are after is a graphic arts process camera, and may be found in companies associated with the printing industry. Some people are in business exclusively for the purpose of making negatives for the printed circuit board industry. The camera used must be dimensionally stable and have distortion-free optics. Otherwise, your finished board may be accurate in one corner but not the other.

When making a negative of PC board artwork, a stable based film must be used. The best would be a glass plate, if you could find one. Glass is very stable under most conditions, but is hard to find and would be quite expensive. A good film for this purpose is 7 mil polyester base safety film.

When exposing the film, backlight the copyboard. This will increase the contrast ratio from about 50 to 1 to 1000 to 1. Needless to say, a backlit negative will have sharper edges and will produce a much finer board. See Fig. 13.

Finished artwork and negatives should be stored flat in a closed container. Temperature should be kept within 35 to 120 degrees F.

Conclusion

This month you have been provided with enough information to be able to go out and design a single-sided board. Next month, we will discuss double-sided and multi-layer boards, as well as the manufacturing process. In the meantime, I suggest you find a simple circuit and try your hand at designing a board. This will make it a little easier to follow next

Jon J. Gallo WA6PTM
1900 Avenue of the Stars, Suite 2000
Los Angeles CA 90067

Announcing the PCF

-- legal aid for ham problems

In Los Angeles County, an amateur is charged with 4 criminal violations for owning a tower in excess of the local 35 foot limit and causing interference to his neighbor's television and stereo receivers. After 18 months of litigation, his legal fees exceed $18,000.

In Oklahoma, 6 licensed CBers running legal power agree to pay $100 fines each after being told by their lawyers that it will cost each of them at least $1,000 to challenge a newly enacted TVI-RFI ordinance.

In Arizona, New York, Pennsylvania, Colorado and Florida, amateurs go to court to fight denials of building permits for towers. Their average legal fees amount to $3,500.

These are not nightmares caused by too much beer and pizza during Field Day. They are merely a few of several hundred legal matters involving the Amateur Radio and Citizens Radio Services which have occurred during the last two years. The newly formed Personal Communications Foundation may be able to reduce the cost of legal services to other amateurs and CBers who encounter similar problems in the future.

Amateur radio was founded on the concept of service, both to the community and to fellow amateurs. Over the years, though noted in only a few amateur publications, numerous attorney-amateurs have literally donated hundreds of thousands of dollars of legal services to fellow hams involved in amateur radio-related legal problems. The rapid growth of amateur radio, coupled with the explosion in the Citizens Radio Service of recent years, has greatly increased the number of legal problems confronting both amateurs and CBers alike and has made necessary some form of organized assistance to the lawyers and licensees involved.

In early 1976, Wayne Green, the editor of *73*, and I exchanged a number of letters concerning a possible series of articles on amateur radio and the law. After working out the ground rules for such a series, Daniel I. Simon WA6EJW, another Los Angeles attorney, and I started preparation of the series. In order to make the articles as interesting as possible, we decided to contact a number of attorney-amateurs throughout the country to gain the benefit of their experience. Among the attorneys we spoke to was Frederick J. Lawson K6JAN, who was and still is involved in a major amateur radio case in Los Angeles County.

Shortly after our initial discussions with Fred, Robert M. Booth, Jr. W3PS, ARRL General Counsel, invited us to attend an informal meeting of attorney-amateurs to be hosted by Marshal Quiat WBØHWQ, a Colorado attorney, which was to be held during the 1976 ARRL National Convention in Denver.

In preparation for the meeting, Dan, Fred, and I prepared a written proposal suggesting the creation of a nonprofit foundation which would serve as a central clearinghouse of legal information for lawyers involved in amateur radio legal matters. This recommendation was submitted to the Lawyer's Committee at a luncheon meeting on July 17, 1976. In addition to Marshal, Bob, Fred, and myself, the meeting was also attended by B. Robert Benson VE2VW, ARRL Assistant General Counsel, Don K. Johnson W5PYA, Carl Markov K6RLP, Donald L. Royer WA6PIR, Chester B. (Barney) Scholl, Jr. K3ZFP, and Larry Perry K4EFV.

The basic concept of a clearinghouse for legal information was endorsed by the attorneys, even though we recognized that there were substantial legal, practical, and monetary difficulties with the draft recommendation. In order to give us time to work on the problems, a follow-up meeting was scheduled in Los Angeles in early September.

During the ensuing 6 weeks, substantial legal research was undertaken and on September 4th the group met at my offices, this time augmented by Richard S. Arnold W6RNP, the Honorable Maurice J. Hindin W6EUV, and Mark Weiss K6FG. Basic plans were formulated, additional research undertaken, and the decision was made to expand the organization to include the legal problems of all aspects of non-commercial, personal communications.

On November 5, 1976, Articles of Incorporation of the Personal Communications Foundation, a nonprofit corporation, were filed with the California Secretary of State. By the time you read this article, applications for tax exempt, tax deductible status will have been filed with the Internal Revenue Service and the California Franchise Tax Board.

The Foundation's principal goal is to serve as a central clearinghouse of legal information concerning all aspects of nonprofit, personal communications by radio, including amateur radio, non-commercial use of citizens radio, and shortwave listening. To avoid any misunderstanding at the outset, the Foundation is not a law firm and cannot, itself,

represent amateurs or CBers who encounter nonprofit communication related legal problems, although compiling a comprehensive list of experienced attorneys in this area is being considered.

Years ago, relatively few amateurs encountered legal problems directly related to the operation of their stations. When problems did arise, attorney-amateurs throughout the country were able to assist them with little difficulty. Today, however, literally hundreds of amateurs and CBers are encountering legal problems yearly and frequently have to turn to attorneys with little or no familiarity with either FCC rules and regulations, prior cases involving personal communications, or the technical aspects of radio. As a result, a substantial portion of the legal fees they are incurring relate to time which the attorney must devote to familiarizing himself with the law in this area and preparing the necessary legal documents. In a few unfortunate situations, the attorney has been unable to locate applicable cases and local courts, without the benefit of such cases, have rendered decisions highly unfavorable to amateur radio.

A number of cases today involve the Citizens Radio Service and some persons have questioned why amateurs should be concerned. The reason relates to how our legal system operates. Our courts follow precedents: i.e., the decisions of other courts in identical or closely related areas. If a court determines that a local municipality can fine CBers for causing TVI or can prohibit CB antennas because they are considered unsightly, other courts are likely to extend such rulings to amateur radio. Moreover, there are more than 15,000,000 licensed users of the Citizens Radio Service. When compared with 250,000 licensed amateurs, it is obvious that CBers outnumber amateurs by close to 40 to 1 and are statiscally more likely to encounter legal problems, particularly those related to zoning and RFI-TVI. It is important to the future of amateur radio that CB-related legal problems receive the same coordination and attention as those confronting amateurs.

Seated, left to right: Hon. Maurice J. Hindin W6EUV, Jon J. Gallo WA6PTM, Carl Markov K6RLP. Standing, left to right: Donald R. Royer WA6PIR, Richard S. Arnold W6RNP, Robert M. Booth, Jr. W3PS, Mark Weiss K6FG. Photo by Robert R. Jensen W6VGQ.

The Personal Communications Foundation hopes to assist all licensed amateurs and CBers who encounter legal problems by developing a comprehensive library of court decisions, legal briefs and related documents, as well as articles and studies relevant to each of these issues. To accomplish these goals, the Foundation is in the process of establishing a number of liaison and working committees. The Governmental Liaison Committee will establish lines of communication with the Federal Communications Commission, Department of Justice, and other appropriate governmental agencies. The Industry Liaison Committee will similarly establish liaison with the Electronic Industry Association (EIA) and other industry groups. Similarly, the Amateur Radio, Citizens Radio and Shortwave Listeners Committees will establish communications with appropriate users, groups, and publications, such as *73 Magazine.*

The Foundation has tentatively divided its areas of primary interest into the following sub-groups:

1. Land use regulation, including all aspects of zoning, variances and conditional use permits, building code requirements, and private deed restriction;
2. Radio frequency interference and television interference (RFI-TVI);
3. The law of nuisance as it applies to personal communications;
4. The role of the Federal Government, the Federal Communications Commission, and the States in the regulation of personal communications including the subject of Federal preemption;
5. Illegal operating practices and procedures; and
6. Miscellaneous areas.

To accomplish these goals, the Foundation plans to establish Amateur Radio, CB and Shortwave Listener liaison committees as well as working committees in each state and Canadian province. It will be the function of the working committees, in conjunction with the liaison committees, to contact both users and attorneys in their area and to secure for the Foundation copies of all relevant court decisions, legal documents, articles, and studies related to personal communications law, as well as publicizing the existence of the Foundation to both users and the legal community. Documents submitted to the Foundation will be reviewed by the Executive Director, Trustees, and other volunteer legal advisers, and will be indexed by both subject matter and state.

Upon completion of the Foundation's legal files, law-

yers, users, governmental agencies, or other individuals with an interest in personal communications law will be able to secure from the Foundation complete information with respect to all relevant decisions and legal documents in any area affecting personal communications. Such a library will greatly decrease the cost of legal services for individual users as well as assisting in the development of a uniform nationwide body of law.

The Foundation is headed by a 24 person Board of Trustees, all of whom are lawyers or judges, five Officers and an Executive Director.

Chairman of the Board of Trustees is Jon J. Gallo WA6PTM, and Vice Chairman is Richard S. Arnold W6RNP, both of Los Angeles, California. Other Trustees include Professor Jerome J. Curtis, Jr. WA6JKQ, Sacramento, California; Joel R. Kirschbaum WB7ESZ, Phoenix, Arizona; Charles Perelman WA6OGW, Beverly Hills, California; Daniel I. Simon WA6EJW, Los Angeles, California; Donald L. Royer WA6PIR, Fountain Valley, California; Chester B. Scholl, Jr. K3ZFP, Sharon, Pennsylvania; Mervyn L. Hecht WB6LEN, Pacific Palisades, California; Richard Bennett K8EHU, Reynoldsburg, Ohio; the Honorable Maurice J. Hindin W6EUV, Los Angeles, California; Harry L. Styron K6MFV, Walnut Creek, California; John A. Dundas II WA6ZCO, Los Angeles, California; Professor Stanley Siegel K8KGU, Los Angeles, California; John C. Hendricks WB9FCB, Chicago, Illinois; Howard F. Shepard W6US, Del Mar, California; Mark A. Weiss K6FG, Encino, California; Fredrick J. Lawson K6JAN, Sherman Oaks, California; the Honorable Williams L. Ritizi W6ONC, Beverly Hills, California; Robert M. Booth, Jr. K3PS, Washington, D.C.; B. Robert Benson, Q.C. VE2VW, Montreal, Quebec; G. M. Howard W5KM, Dallas, Texas; Monroe Y. Mann WA2MAJ, Port Chester, New York; and Robert H. Hajek K9LTN, Chicago, Illinois.

Officers of the Foundation are Jon J. Gallo WA6PTM, President; Richard S. Arnold W6RNP, Vice President; Carl Markov K6RLP, Secretary; William S. Finklestein WB6JAO, Assistant Vice President, Security Pacific National Bank, Treasurer; and Ronald Ruby WB6MEB, C.P.A., Controller-Accountant.

Day to day operation of the Foundation is carried out under the direction of Carl Markov K6RLP, Executive Director.

Although the majority of services are being donated without charge to the Foundation, the Foundation anticipates heavy expenses in terms of mailing, telephone costs, printing and reproduction of documents, and salaries for a limited number of part-time employees of the Foundation who handle the day-to-day administrative tasks. Contributions in any amount to offset our costs are welcome.

In addition, interested individuals or clubs may become members of the Foundation. Four classes of membership are available: associate membership for a yearly contribution of $10, full membership for a yearly contribution of $25, supporting membership for a yearly contribution of $100, and life sustaining membership for a single contribution of $250 or more. The Foundation anticipates publication of a quarterly newsletter summarizing relevant legal developments, and all classes of members will receive the newsletter.

Full, supporting, and life sustaining members will also have full voting rights for the selection of trustees.

The Foundation has applied for tax exempt status, and a favorable ruling is anticipated within the next 60 days or so.

Membership applications have not yet been printed due to lack of funds. However, memberships are available at this time and requests for membership, accompanied by your check payable to the Personal Communications Foundation, may be mailed to the Executive Director, Carl Markov, 915 West Lancaster Boulevard, Lancaster, California 93534. The request for membership should include your name, address, telephone number and FCC Amateur or Citizens Radio Service callsign, if any.

Although legal and tax considerations require that the Board of Trustees be composed of lawyers and judges, membership in the various liaison and working committees is not similarly restricted. Anyone having or willing to develop the necessary background and devote sufficient time is welcome to serve on the committees. Membership applications sent to the Executive Director may also request committee membership. Requests should specify the committee desired and set forth any special expertise which will assist the Executive Director in evaluating such requests. Committee membership is open to all, but persons holding any class of membership in the Foundation will receive priority in committee assignments.

Contributions, requests for membership, and requests for committee assignments should be sent directly to the Executive Director. Requests for other information, comments or suggestions may be sent either to the Executive Director or to Jon J. Gallo WA6PTM, President and Chairman of the Board, Personal Communications Foundation, 1900 Avenue of the Stars, Suite 2000, Los Angeles, California 90067.

The Personal Communications Foundation has been formed for you. It can only function with your assistance. ■

TO: Personal Communications Foundation
c/o Mr. Carl Markov, Executive Director
915 West Lancaster Boulevard
Lancaster CA 93534

☐ Please send more information.
☐ I would like to be a member.

Enclosed is my contribution:
☐ Associate ($10) ☐ Supporting ($100)
☐ Full ($25) ☐ Life ($250 or more)

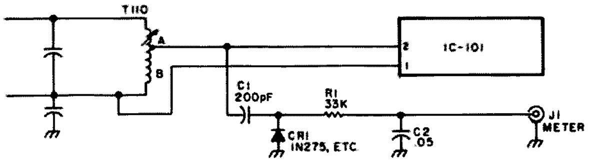
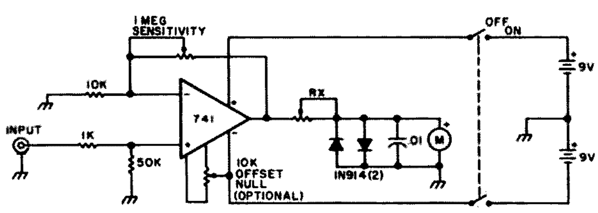
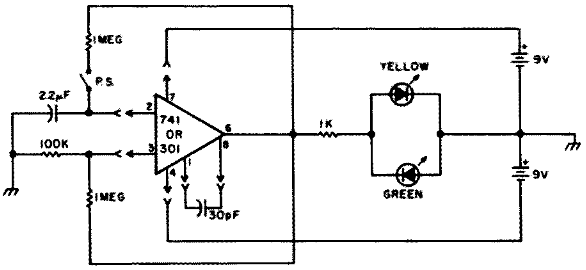
Circuits²

Want a free copy of any 73 publication? Sure you do. Just send in your favorite circuit, or even one that you don't especially like. If we print it, you take home the book of your choice.

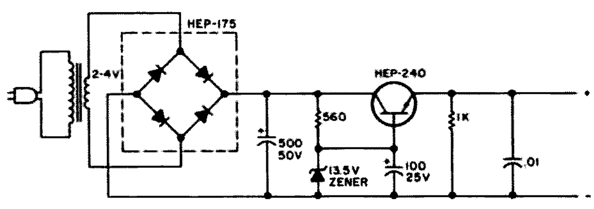


A relative signal strength meter for the GENAVE GTX-200 and GTX-10. This circuit is for a 25 uA meter movement, any style, which may be mounted external to the rig, or internally with a shoehorn (!). CAUTION . . . do not short pins 1 or 2 of IC-101 to ground or ZAP! Parts are mounted on the foil side of the board by short leads and a dab of glue. The meter lead goes to a phono socket on the rear panel under the power lead (for external meter). Be sure to use a shielded lead from the socket to the meter. If you have a meter with a less sensitive movement, say from 200 uA to 1 mA, the following amplifier circuit, wired in the meter case, will give you more than ample meter deflection with good dynamic range. $R_X + R_{meter}$ should equal 5000 Ohms. Add 10k offset null pot to 741 op amp if you want the meter to go to zero with no signal. Thanks to Larry Chrisman K9OXX (from State of the Arts, *Allen County ARTS, Ft. Wayne IN).*

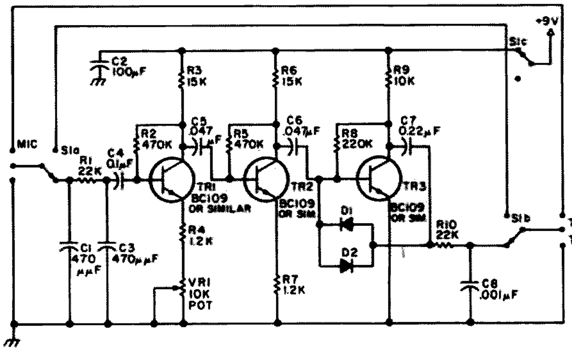




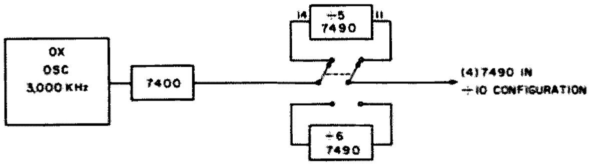
Here is a clever device to test those surplus 741 and 301 operational amps available from 73 advertisers. The two LEDs provide the necessary information when the op amp is inserted into the test circuit. If the op amp is OK, the two LEDs will flash alternately with a one second period. No flashing or illumination indicates an output fault. If one of the LEDs glows continuously, one of the inputs is faulty, and asymmetric blinking indicates a leakage problem. The circuit uses standard components throughout, and no power switch is required, as the circuit draws current only when an op amp is being tested. Thanks to J. Lawrence GW6JGA (from CQ-TV, *Journal of the British Amateur TV Club).*



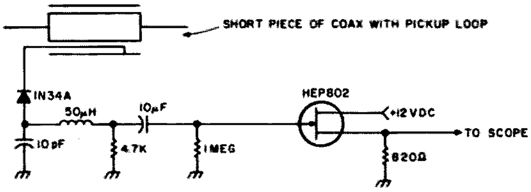
Need a simple regulated supply for your 2m rig? Try this one. The transistor may be heat sinked directly on the side of a minibox, and the transformer is any unit rated at five Amps and 24 V. Standard components are used throughout. This supply is humfree, and regulation is good — the output voltage varies only .2 V between transmit and receive. This supply is especially for smaller transceivers such as the TR-22C, used by many during relaxation TV sessions in the evening. Thanks to W8DYF.



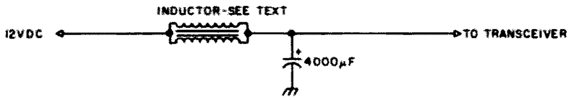
Speech amplifier and logarithmic clipper for use with SSB transmitters. The circuit reduces the speech bandwidth to about 500-3,000 Hz, thereby creating very little distortion. Power can come from the transmitter or a separate battery. Thanks to P. Burnett G4BLL (from The Short Wave Magazine, *August, 1976).*



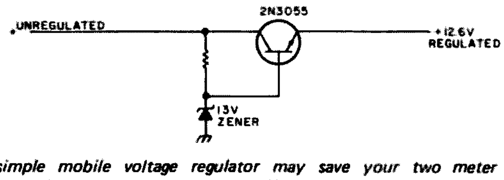
A selectable 50/60 Hz source for 12 or 24 hours with a 50250 clock chip. To have both in the same clock requires a source of selectable 50 Hz or 60 Hz frequency. A 3 meg xtal was picked because it seemed like a good choice, but a 30 kHz or 300 kHz would do as well (because when divided by 5 you get a 6 in the answer and when divided by 6 you get a 5 in the answer). Thanks to Frank W. Knottingham K7QCM.



Here's a quicky for ATV operators. This "air monitor" allows the monitoring of transmitted ATV signals with a scope. It is particularly handy in checking sync levels and shape. The pickup and detector can be mounted on a tiny PC board and installed in a minibox along the transmission line. The circuit can then be used to monitor the outgoing signal while adjustments to the modulator are made. Thanks to W3DID (from THE MILLIWATT, *a publication of the Baltimore Radio Amateur TV Society, vol. 1, no. 3).*



Bugged by alternator whine in your ham or CB transceiver? If so, try this super simple, but effective, whine filter. The LC circuit is a low pass filter which shunts the high frequency "whine" component on the dc to ground. The inductor consists of a 7 inch ferrite rod, ½ inch in diameter, wound with a single bifilar layer of No. 14 Formvar copper wire. The bifilar winding is formed by holding two wires side by side and winding the length of the rod. The two ends on each side are soldered together, resulting in an inductor capable of handling 10 Amps. The capacitor is a 4000 uF electrolytic. The negative end must be well grounded to the frame of the vehicle in order for the filter to be effective. Thanks to WB4EXW (from CVRA Repeater, *Journal of Carolinas-Virginia Repeater Association, Burlington NC).*



This simple mobile voltage regulator may save your two meter or CB transceiver if the voltage regulator fails. The 2N3055 should be heat sinked if current drawn by the rig is in excess of 2 A on transmit. This circuit will do little under normal operating conditions, but could save your rig if the vehicle's electrical system loses regulation. Thanks to WA2LPB.

Build Your Own Car Regulator

- - solid state

Many car owners, at one time or another, experience electrical system problems usually resulting from a dead battery. In many instances, the battery is blamed for the malfunction when, in actuality, the electromechanical type voltage regulator is the real cause of the problem. This is usually the case, even though the voltage regulator may appear to be functioning properly.

To understand why this happens, consider the fact that a properly charged and maintained lead-acid storage battery should last the life of your automobile. When an early failure occurs, it's usually due to the voltage regulator consistently undercharging or overcharging the battery in the system. In fact, more battery failures result from improper voltage regulation in automotive electrical systems than for any other reason.

Excessive undercharging will cause the battery plates to become covered with lead sulfate, commonly referred to as "sulfating." On the other hand, overcharging a storage battery raises the temperature of the electrolyte, resulting in extreme oxidation of the plates, which eventually crack or buckle. The end result of both of these improper charging conditions is the same . . . *a dead battery.*

Electronic Voltage Regulation

To overcome the above problems, it's necessary to regulate the charging voltage at the proper level. It's up to the voltage regulator to maintain the proper system voltage and, for many years, this task has been accomplished with an electromechanical device. The main disadvantages of these devices are voltage variations due to temperature changes, unadjustable voltage settings, and mechanical type failures.

Many auto manufacturers have recognized these problem areas and as a result are switching over to solid state designs. In fact, if you own a late model car, it may already have an electronic voltage regulator. However, there are still many cars in existence today with the old style electromechanical regulator. If yours happens to be one, you can easily update it with a precision, electronic voltage regulator.

For less than $10 in electronic components, you can build your own solid state voltage regulator that should outperform any electromechanical regulator on the market today.

How It Works

As indicated in the schematic diagram (Fig. 1), this solid state automotive regulator uses a minimum of components to achieve high performance without sacrificing reliability. The heart of the

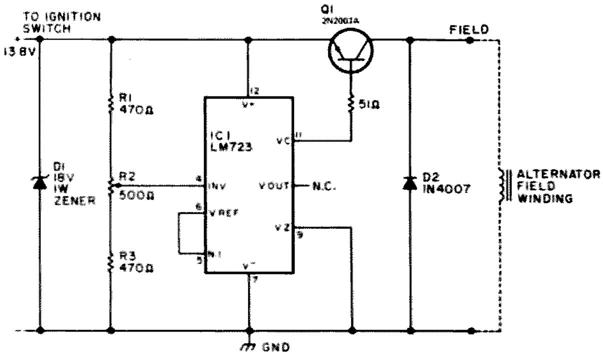

Fig. 1. Schematic. D1 — 18 volt zener diode, 1 Watt; D2 — 1N4007, 100 piv, 1 Amp rectifier; IC1 — LM723 voltage regulator (14 pin, DIP); Q1 — 2N2063A (SK3009) 10 Amp PNP transistor; R1, R3 — 470 Ohm, ½ Watt, 10% resistor; R2 — 500 Ohm, 10 turn trimpot; R4 — 51 Ohm, ½ Watt, 10% resistor; Miscellaneous — TO-3 transistor socket, 14 pin DIP socket, barrier terminal strip, TO-3 mica washer kit, PC board, minibox, optional relay (see text).

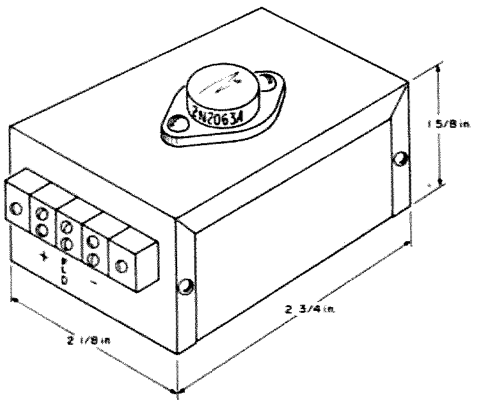

Fig. 2. Construction details.

unit is the LM723 precision voltage regulator IC, which is internally temperature compensated. This integrated circuit is connected as a switching type regulator to control current flow to the field of the alternator. Resistor R2 is adjusted to maintain a system voltage of 13.8 volts, the fully charged voltage of most standard car batteries.

If the alternator tries to produce a voltage above the set level, the LM723 turns off the pass transistor, Q1, thereby cutting off field excitation in the alternator. When this happens, the output voltage from the alternator begins to drop. As soon as the output level drops below 13.8 volts, the regulator turns the field current back on to raise the output voltage. This cycle is repeated hundreds of times a second to maintain the alternator's output voltage precisely at the set level.

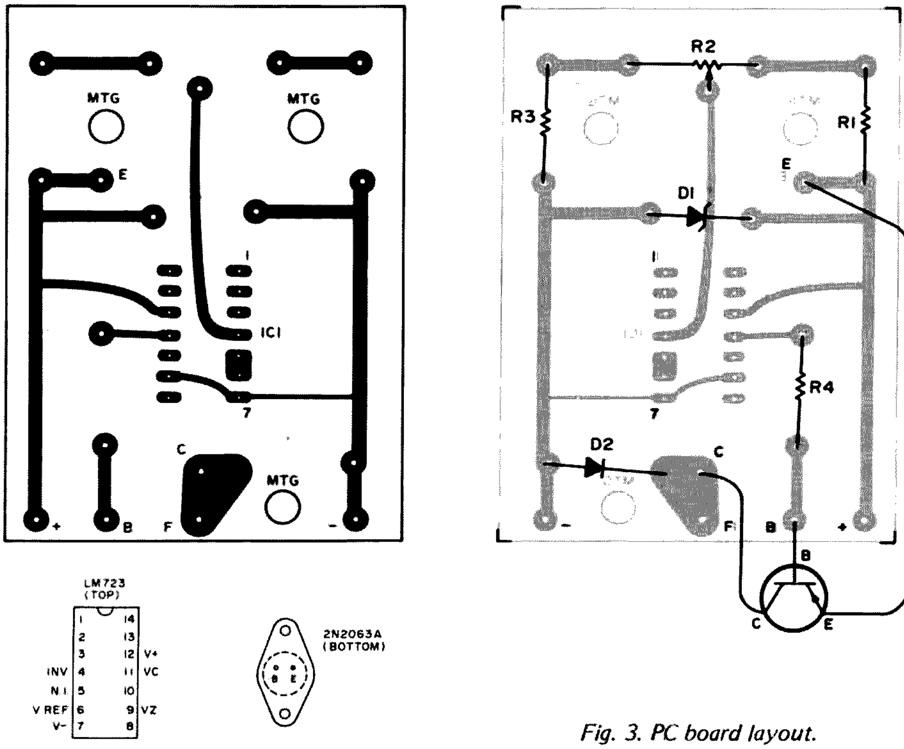

Fig. 3. PC board layout.

The external pass transistor, Q1, is required to handle the large field current of most alternators (approximately 3 Amps), since the LM723 has a maximum output current capability of 150 mA.

Construction Details

The solid state voltage regulator may be built in a small minibox (2-3/4" x 2-1/8" x 1-5/8") as shown in Fig. 2. Transistor Q1 is mounted on top of the minibox, which is used as a heat sink. Insulate the transistor from the metal case using a T0-3 transistor socket and mica washer kit. This is necessary to prevent the transistor's case (collector) from shorting to ground.

A barrier type terminal strip (3 terminal) is used to bring the BATT, GND and FIELD connections out. If a relay is required (see installation details), you may elect to construct the unit in a larger minibox to house the relay. Also, a six terminal barrier strip will then be required to make external connections to the relay.

In some installations, depending on the mounting location of the regulator, you may want to seal the enclosure for moisture protection. However, if the mounting location under the hood is carefully chosen, this should not be a problem.

The external pass transistor is not critical, and almost any 10 Amp, PNP transistor will be adequate. However, plan to use only a DIP version of the LM723 and not the T0-5 version. The reason for this is that the DIP version has an internal reference zener diode (Vz) and the T0-5 version does not. The T0-5 may be used, but you will have to add an external zener reference diode. Also, the printed circuit board layout (Fig. 3) has been designed for the DIP version.

How to Install Your Electronic Regulator

First, try to obtain a copy of the schematic diagram for your automotive electrical system. Most local libraries will have automotive manuals containing this type of information. You should become thoroughly familiar with this diagram before proceeding with the installation.

Referring to Fig. 4, determine which system best fits your own car. Four basic types of alternator systems are illustrated: Ford/Autolite, Delcotron/GM, Motorola/AMC, and the Chrysler/Plymouth system with an ammeter. With the exception of Chrysler/Plymouth, most systems will require an external relay to maintain the alternator charge indicator light function. However, if

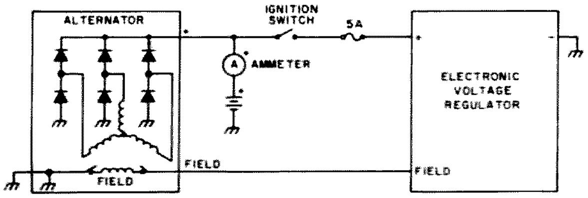

Fig. 4(a). Simplified diagram for a typical electrical system containing an ammeter in lieu of the alternator indicator light. This type of system does not require an external relay to convert to an electronic voltage regulator.

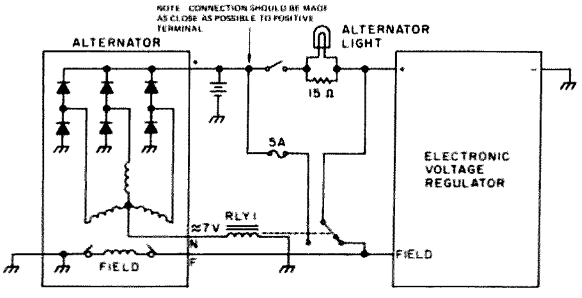

Fig. 4(b). Simplified diagram for a typical Ford electrical system with a charge indicator light. This type of system requires an external relay to maintain the function of the indicator light. RLY1 — any 6 volt relay with 3 Amp SPDT contacts.

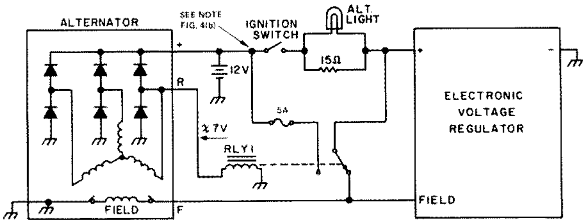

Fig. 4(c). Simplified diagram for a typical Delcotron (GM) electrical system with a charge indicator light. This system also requires an external relay if you want to maintain the function of the indicator light. RLY1 – any 6 volt relay with 3 Amp SPDT contacts.

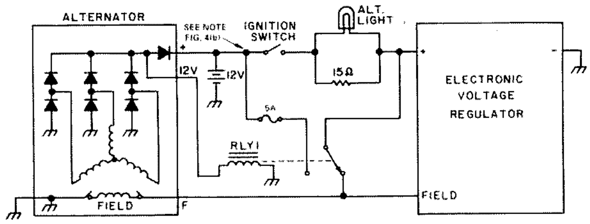

Fig. 4(d). Simplified diagram for a typical Motorola (AMC) electrical system with an internal isolation diode. An external relay will be required to maintain the function of the indicator light. RLY1 – any 12 volt relay with 3 Amp SPDT contacts.

you install an external ammeter, you can eliminate the requirement of the relay. Simply connect the regulator as shown in Fig. 4(a).

The next step is to find a suitable location under the hood to mount the electronic regulator. Preferably, this location should be near the battery and away from areas subject to moisture or excessive heat.

Disconnect the old regulator and mark each of the connecting wires for future reference, and use crimp-on connectors to connect the new regulator to the system. This will maintain the integrity of the original system connections should you ever want to convert back to the original configuration. If an external relay is required, mount it in a protected space, preferably with a dust cover or within the regulator enclosure.

After the unit is installed, recheck all wiring to insure that the system is properly connected. Before starting the engine, turn off all loads until the system voltage is properly adjusted and stable. After the engine is started, adjust the system voltage (with trimpot R2) for 13.8 volts at the positive terminal of the battery.

Check to see if the regulator is functioning properly by increasing the engine speed and adding loads to the system. The voltage should remain constant. Note: At slow idle, with loads turned on, the voltage may drop slightly, since the alternator is not producing at its rated output. At cruising speed, however, the correct voltage should be maintained if the system is operating properly.

Conclusion

This completes the installation and check-out of your electronic voltage regulator. It should provide many years of troublefree operation in addition to extending the life of your lead-acid battery.

As a final suggestion, you may want to monitor the system voltage on a continuous basis for the first few weeks after installation. If no problems are experienced during this initial trial period, it can be safely assumed that the voltage regulator is compatible with your particular electrical system. ■

The HAPPY FLYERS

-- fun and public service

Few hams have operated any length of time without observing interference of some type. Whether accidental or intentional, it still has the same effect on a QSO (and our blood pressure). The need for devices and procedures to locate interference – and its interrelationship with finding downed aircraft – has revealed an unexpected opportunity for hams. About 5,000 volunteers are needed, plus the cooperation of many repeater groups across the nation.

Many stories have been passed from father to son and mother to daughter regarding the subtle sounds of opportunity knocking. With each story comes an imaginative narration of the consequences and/or blessings that occurred as a result of someone's reaction to the particular opportunity. Many of us have dreamed of that special opportunity that would open the door and make a dream come true.

In 1979, the International Telegraphic Union (ITU) will convene a general World Administrative Conference in Geneva, Switzerland. During the conference all the ITU rules, regulations, and frequency allocations applicable to the orderly use of the spectrum from 10 kHz to over 300 GHz will be examined in detail – and this includes the amateur radio service. In light of their voting structure, many knowledgeable hams are concerned about the outcome of this conference. The performance of some U.S. amateurs during emergencies (the Guatemala quake) and their daily operating practices leave something to be desired if we wish to make a good impression on our valuable voting friends in the ITU. On the list of attributes most likely to influence friends and votes: bad manners, poor operating practices, excessive power, and intentional interference.

It was the increasing problem of intentional and accidental interference that led the HAPPY FLYERS to the door of opportunity that now awaits opening by all U.S. amateurs everywhere (HAPPY stands for "Hams And Pilots Piloting & Yakking." – Ed.).

Our first two years were spent in organizing, recruiting, bimonthly fly-ins, our annual fund-raising "Flying Poker Party" (pick up a playing card at five airports – best hands win numerous donated prizes), public service flights, transporting hams and families in emergencies, and flying in Civil Defense drills. The number in Squadron #1 had nearly reached 200 when jamming became a severe problem on our local repeaters. Somewhere around the same time, Congress passed the ELT (Emergency Locator Transmitter) law for all U.S. aircraft. They failed, however, to make proper provision for finding downed aircraft fortunate enough to have a squawking ELT and a survivable crash.

It was the culmination of all these events and facts that caused me to accept an invitation to attend a meeting of the San Mateo County Sheriffs Air Squadron. Word was out that they had a state-issued RDF unit to issue to the proper pilot for installation in his plane. He would be the official search pilot for the county. I was greatly interested in the possibilities of adapting this special equipment to the 2 meter FM band, in order to locate jammers.

The long and short of it is that I acquired the job and the unit. Jim Williams K6HIO and I took it apart before installing it in our plane. We made numerous test flights on the amateur and aircraft frequencies. To our amazement, no modification of the state unit was necessary, provided we kept the FM rig out of saturation with a step-attenuator. We found all signals we looked for in the experimentation. The first real test was the Western States Sheriffs ELT search competition. Deputy Don Short and I located the signal in 6 minutes. I won 1st prize – and then was barred from all future electronic search competition (due to our excessively rapid find compared to the competition). Our first real plane wreck took 16 minutes from signal contact. Later, we believe we located the first jammer by airborne RDF – 22 minutes flying time straight over his house (Don Smith W6NKF, Vice Commander, Squadron #1, Dick Smith WB6WPZ, and Art Sinclair W6FKQ were at his door within the hour).

We soon developed our own inexpensive RDF printed circuit boards – one for simple AM and one with an automatic attenuator for FM/AM. We were all set to end jamming in our area. Soon many units were being built, and the jamming was shortly cut about in half (apprehension capability has a decided effect on jammers).

Then we began to see the problems in the ELT program. Poor construction standards of the first ELT units caused so many false alarms that the program went into almost immediate disrespect. Real accidents often failed to trigger the ELT, and those that did were not found easier. Few people had RDF equipment, and many who did were unable to find the signals due to their lack of understanding reflections, multipath, and the operating characteristics of the new

equipment. Experienced hams had little trouble, but seasoned pilots trained to fly low and look could not make the fool things work properly (but then that's another story we usually cover in our free RDF seminars).

As time passed, more and more problems began to surface. The HAPPY FLYERS had already begun their free RDF seminars for pilots and hams. Then a plane crashed, two miles from at least 5 ham repeaters and within VHF range of at least 5 FAA facilities that should have heard the ELT. Twelve hours elapsed before they were found. The *Oakland Tribune* reported that they were found by teenagers by accident – not by modern RDF or search personnel. Subsequent investigation turned up the fact that the FAA has officially ceased monitoring the 121.5 emergency frequency in many metropolitan areas, due to the numerous falses and tests.

We had been working on remote RDF for our repeaters to quickly locate jammers. When I read how one survivor was pinned, bleeding in the wreckage, with his brother thrown clear and unconscious, I thought about what a shame it was that we didn't have the remote RDF finished and a command at the repeater to switch to 121.5 for DF. This incident began a fabulous series of events.

Members of Squadron #1 turned their efforts from the jammers to an analysis of ELT problems. We sought input from other hams and HAPPY FLYERS through our regular column in *Worldradio News.* What we came up with is the outline and nucleus of a proposal that could save the future of the ELT program, save untold lives, and give amateur radio operators, their equipment, and their ingenuity a needed boost in the eyes of the general public (and the WARC for the '79 conference).

Opportunity knocks loudly at your door. We can save lives, save a worthwhile ELT program, save billions of dollars in search and satellite funds, restore 121.5 to its useful emergency value, impress the public, and prove beyond the shadow of a doubt that we are capable of providing services for free that are not presently available by any other means. In addition, the equipment is usable on the ham bands and will give instant readout to buttonpushers and jammers. Interested? Read on.

The artist's conception drawn by our International Vice Commander Paul Hower WA6GDC shows a broad integrated ham monitoring proposal. It is a simple and logical approach originally envisioned as an areawide, interclub plan to obtain instant bearing information on jammers through the use of our HAPPY FLYERS remote RDF and an organized intergroup coordinator. Due to the design of our DF device, we can get instant readout to even a "buttonpusher."

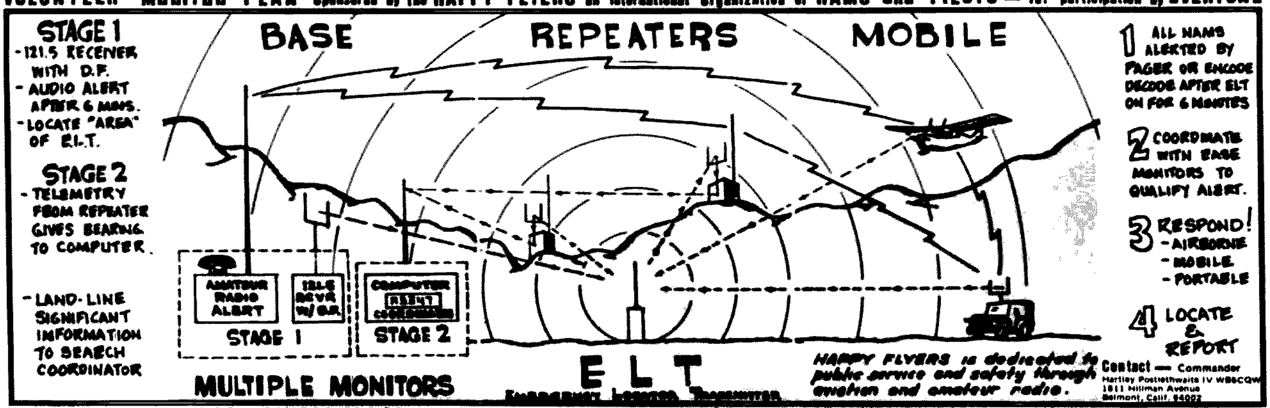
We presented a general outline of our plan to Rick Goodman, Vice President of the National Association of Search and Rescue Coordinators, at their '76 convention in Cheyenne, Wyoming. Rick, an active Albuquerque ham, informed me that his repeater club had already installed a 121.5 receiver at their repeater. He was greatly enthused about the comprehensiveness of our plan. They had no time-lockout and were rebroadcasting the ELT tones as the alert. They are now incorporating our ideas into their system. His ham group had made a terrific sound/slide show on amateur participation in search and rescue. We purchased a copy, added slides and sound covering our proposal, and are showing it in our RDF seminars and at civic groups – Rotary, Jaycees, Lions, etc. – a tremendous PR boost for amateur radio. Our group has the motto, "There is no limit to what you can do if you don't care who gets the credit." It is a great pleasure to work with people like Rick, Ray Andrews K9DUR, Bruce Gordon of CAP, Bob Kolsters, Commander, Western States Sheriffs, and our international squadrons of hams and pilots, the HAPPY FLYERS. Everyone will have to work together on a local scale, but within a national set of standards and guidelines for the program.

Due to the construction delays expected, we plan to set up the ELT Monitor Program in two basic stages. The first stage might be described as the "Alert and Elimination" stage, as shown in the drawing. Used commercial tube receivers are being made available to hams by a nationwide aircraft radio company through the HAPPY FLYERS. These receivers will be distributed to repeaters and to volunteer low band hams who live in remote wilderness areas not covered by repeaters, FAA, or military facilities.

We then hope to secure volunteers who live near the nearly 5,000 U.S. airports, to get inexpensive 121.5 receivers. Repeater and individual receivers will be equipped with a time-lockout decoder (such as the one designed for the HAPPY FLYERS by Jim Williams K6HIO), to prevent false alarms by voice communications or ELT tests. ELT tests are authorized by law, the first five minutes of every hour. The lockout decoder (parts cost under $5) will be set for about six minutes to eliminate additive individual

Nation-wide E.L.T. Program

VOLUNTEER MONITOR PLAN Sponsored by the HAPPY FLYERS an International Organization of HAMS and PILOTS — for participation by EVERYONE



STAGE 1 - AREA WIDE MONITOR PROGRAM

1. Exsisting Ham & CAP repeaters install 121.5 receivers with special time lock-out decoder to by-pass ELT test period and voice communication for 6 minutes. This provides high level, wide area coverage, thru thousands of exsisting repeaters.
2. Low-band Hams and interested citizens would install low cost monitors in homes in remote wilderness areas not covered by repeaters, FAA, or military facilities.
3. Every airport in the Country to hove an individuol volunteer monitor with same lock-out decoder. Receiving range cut to hear only one Airport. Purpose of these monitors to immediatly localize false Airport triggering of ELTs.
4. When 6 minute test lock-out exceeded, repeaters to generate emergency tone (2000 and/or 200 cps) to "Silent Monitor" decoders and paging receivers alerting Search and Rescue personnel and Coordinators alike.
5. Proper coordinator will assemble information from repeater and individual monitor reports. Airport falses would be immediatly identified by Airport volunteer.
6. Individual alert of all SAR personnel via wide coverage repeater tone-alert will cause pilots and ground crews to remain available while validity of emergency is verified by coordinators. Call-up can be accomplished thru repeaters or phone. Acquiring crews at odd hours will be greatly simplified.
7. SAR personnel can be reached at social functions, work, in car, or during sleep hours via extensive coverage of repeaters and use of its tone alert. Airborne search pilots would also be able to be contacted. TIME SAVED, SAVES LIVES.

STAGE 2 - ELECTRONIC DIRECTION FINDING

1. Remote RDF capability will be added to repeaters and be available an command of coordinators. Bearings from two or more repeaters will be plotted for probable area of trouble. Low cost tone telemetry has been developed for this.
2. Remote individual wilderness monitors will add low cost RDF to supply bearing information with reports via radio or telephone.
3. Airport monitors will odd portable RDF capability & assist in locating offender.
4. Hams to assist in equipping more planes with low cost RDF capabilities.
5. Computer equipped Ham repeaters will inter-link for rapid calculation of more precise intersections of multiple bearings.
6. Continue free educational Seminars for Hams, pilots and other interested people.
7. Encourage pilots to report their own accidental triggerings (to cancel searches)
8. Encourage more pilots to monitor 121.5, in flight, and at shut-down.
9. Continue conducting free check rides for pilots & observers in RDF techniques.
10. Issue gold embossed DF rating cards for passing writen & flight/ground checks.

ADDITIONAL PROPOSED GOALS

1. Visit with Congressional leaders, FAA, FCC officials to effect necessary changes.
2. Establish a legal proceedure to silence illegal ELT transmissions.
3. Provide Scott AFB with current lists of volunteers, capabilities, and locations.
4. Continue to seek donors of used commercial equipment, receivers, pagers, etc. to minimize overall costs to SAR volunteers in the program.

tests which would be possible with monitors who may have many airports in their receiving area.

ELT signals exceeding six minutes will trigger a tone oscillator (suggested frequencies are 2,000 and/or 200 Hz) which can be decoded by silent monitor tone decoders and belt paging receivers of participating search and rescue personnel – hams, volunteers, FAA, CAP, and Official Area Coordinators.

The elimination process will be automatically started by the tone alert. Participating airport volunteers could report to the coordinator an "all clear" or "I hear it." In less than 30 minutes, all airports would be checked. 100% "all clear" would signify a possible valid emergency. Repeater coordinators from various high location repeaters would then be polled and a second elimination process would give the general location by absence or presence of the ELT alert tone.

Little imagination is necessary to see the many benefits of stage 1 – high level monitors, airport monitors, wilderness monitors, personnel notification, general search area probabilities, 24 hour reliability by the silent monitor and lockout timer, rapid response, multigroup participation, favorable ham PR with the community, further evidence of the value of the amateur bands and the technology that has historically shown that hams can often fill design gaps.

Stage 2 will add RDF (Radio Direction Finding) capability to repeater and individual monitor stations. Computer-equipped repeaters will link for automatic processing of bearings. Hams will help train non-electronically oriented pilots and search personnel in the techniques of transmitter hunting (present airborne RDF equipment is now accurate to a couple of feet at crossover). Hams will continue designing the special electronic devices needed (like the VOX audio repeaters designed by the HAPPY FLYERS and Rick's New Mexico group).

As you remember, I mentioned earlier that this all ties in with our jammer problem. The same DF equipment will work on ham, aircraft, and marine frequencies. We will have an established interclub group, with equipment, procedures, and skills sharpened by experience. We will have assistance from other groups (members of Western States Sheriffs Air Squadrons have volunteered to assist in airborne jammer hunting with their ELT RDF units). Jammers think twice before pushing the button when the chances of being caught are high. You don't park in the same illegal parking space if you get a ticket every time.

Where do *you* fit in? Each area will need to set up its own program. This means leaders, workers, builders, listeners, donors, and equipment. You have the choice as to how much you can or will do to further this program. The HAPPY FLYERS is an international volunteer organization of hams, pilots, and flyers (those interested in flying but not necessarily hams or pilots). We are a no dues, no fees organization, with no paid employees.

Due to our nonprofit structure and our no staff operation, we hope to see as much accomplished at the local levels as possible. We will provide information and all other help possible. A self-addressed stamped envelope on all correspondence will be greatly appreciated – both from the time and money standpoint. As you begin to organize, we will need to know who is in charge of the operation in your area. As we receive word that used commercial equipment becomes available either through donors or at drastically reduced prices, we will need to know whom to pass the information on to. Many companies would rather not be bothered by calls from individuals, but will make master arrangements with groups like ours. Our thanks to those who have already called.

As you can see, we are really "into" this. I think you have the main ideas. Your suggestions are also solicited. You've got the ball – do something with it. ■

10 and 11 Meter Predictions

- - buy your stock now

For the past several months, I have been planning to write an article on the next sunspot cycle (which, by the way, appears to have started last November, very slowly) and its effect on CB radio. But prudence has held me back. I have lived with the sun through three high sunspot periods as the Propagation Analyst for RCA Communications and have learned to have a great deal of respect for the whims of this great ball of atomic fire. However, I have today thrown caution to the wind and have decided to go through with it. Some stories that have appeared in newspapers and magazines recently are responsible for this change of mind.

The stories that I have read were telling the CBers that their band (11 meters) is likely to be in a shambles during the next sunspot high due to long distance co-channel interference on account of sunspots and that the CBers will be all fouled up. I do not agree with this pessimistic view. If the forthcoming high was going to be like the high we had in 1957-58, I would tend to agree with them somewhat, but I do not think that it is. In fact, I expect the next high period, which should run from 1979 to 1982, to be the lowest we have had since the early 1800's.

I estimate that the yearly mean of the forthcoming cycle high of 1979-82 will be about 20 to 25 spots higher than the cycle high that took place between 1802 to 1805. I have increased the number by 20 to 25 because the astronomers will probably count more spots today with better telescopes than the astronomers did in the early 1800's. The comparison is given in Table 1.

My own experience with sunspot numbers and frequency variations has indicated to me that a count of 90 to 100 is necessary to bring the 10 and 11 meter band into operation *with any degree of consistency*, although temporary bursts of sunspot activity can bring it to life for shorter periods of time. Old time hams are, of course, well acquainted with the relationship that exists between sunspot numbers and the maximum usable frequency (MUF), and no doubt many of the CBers are also, but for the benefit of those who do not know this, perhaps a few words of explanation are in order.

Ultraviolet radiations from the sun create and sustain the ionosphere, which makes it possible to communicate over great distances with high frequency radio (HF). Since sunspots radiate very strongly in UV, it stands to reason that the more sunspots the sun produces, the stronger the ionosphere will be. A strong ionosphere will reflect back to earth the higher frequencies and, if there are enough of them, the 27 and 28 MHz band of frequencies (10 and 11 meters) can be used for communication over vast distances – often six to eight thousand miles. And this they can do with very low power. When sunspots are scarce, these frequencies are usually good for short distances only.

When operational, the 10 and 11 meter bands of frequencies are at their best when the sun is shining on both the transmitter and the receiver at the same hour. They are rarely useful for long distances when a part, or all, of the ionosphere is in darkness between the transmitter and the receiver. In addition to a sunspot number effect upon the MUF, there is also a very pronounced seasonal effect. For any given sunspot number, the ionosphere will reflect a higher frequency in December than it will in June . . . all the winter months are higher than the summer months.

I have the actual frequency records on commercial radio circuits for June and December, 1968, wherein the highest useful frequency was recorded every two hours of the day. June, 1968, had a mean sunspot number of 110 and the average of the highest frequency useful during the daylight hours was 22.2 MHz, while in December with a mean sunspot number also of 110, the average of the highest frequency useful during daylight hours was 25.3 MHz. In June, the highest frequency during the month was 26 MHz, and that appeared for only one day. In December, the highest frequency was also 26 MHz, but was useful for 18 days. These recordings were taken on high speed commercial circuits working at 240 wpm (four 60 wpm teletypes on multiplex) and had to provide good copy for several hours per day. Circuits with less stringent performance parameters could be used above 26 MHz; therefore, we can say that 26 MHz was not the full MUF, but it was close.

We will now pick a year with about 70 sunspots in December and analyze that for the December frequencies under these sunspot conditions. The sunspot number records show that December, 1966, had a sunspot count of 70. My frequency records show that the monthly average of the highest frequencies used was 21.5 MHz, with 24 MHz being the highest, but it appeared for only one day during the month. The next highest was 22 MHz, which appeared in the records for 16 days. This gives us an idea of what to expect during the winter months of the next sunspot high if my predictions are right.

An interesting comparison can be made for December, 1957, with a sunspot number of 239. The records show

RECORDED		PREDICTED		COMPARED WITH 1958 HIGH	
Year	count	Year	count	Year	count
1802	45	1979	65-70	1956	142
1803	43	1980	63-68	1957	190
1804	48	1981	68-73	1958	185
1805	42	1982	62-67	1959	159

Table 1.

that the monthly average of the highest daylight frequency observed was 27 MHz. The highest frequency observed for the month was 28 MHz (the ham band frequency of 28 MHz was checked every day to see if it was there). We had no way of knowing what the real MUF was, however, because of frequency limitations. Also, these observations were made on east-west transatlantic circuits.

A ham friend of mine read this manuscript up to the end of the preceding paragraph. When he had finished, he turned to me and said, "Well, what's it gonna be? You forecasters are all alike – ambiguous and evasive, nobody can pin you down." (This fellow was an insurance agent – imagine an insurance agent calling somebody else ambiguous.) He told me to put my neck on the block. So here it is, October to February, 1979/1982, daylight paths only on east-west circuits:

A. The 10 meter band (28 MHz)

This band will be spotty, coming to life with periodic bursts of sunspot activity. Far below 1958 and 1968 qualities.

B. The 11 meter band (27 MHz)

The CBers will not have any important co-channel interference problems (unless somebody decides to put his on a high gain antenna).

C. The 15 meter band (21 MHz)

This band will be the workhorse band for DX.

D. The 20 meter band (14 MHz)

This band will also be useful as a secondary workhorse band and with performance pretty close to that of the 15 meter band.

Forecast completed December, 1976. ■

had, along with a good idea of how his rig could be identified (off frequency, lousy quality, and cold solder joints).

Sorry, Dave; just kidding.

It turns out that Dave's follow-through was of great interest to the police in Hanover. It appears that the "Bad Guy" was a suspect in a number of unsolved cases, and they had never had enough evidence to search his home. With the information that Dave and the 07/67 "Mission Impossible Team" furnished, a Heathkit two meter rig was recovered, along with a few CB rigs and a stolen gun. I understand the investigation even led to recovery of several thousands of dollars of household items and put an end to a housebreak ring in the South Shore.

So to those of you who may encounter a "breaker," play it cool . . . give him the low key approach, and then pass the information along to the proper authority. Who knows, you might catch a thief . . .

By the way, the 2,000,000 to 1 odds did pay off. It was Dave's rig and he has it back on the air (except for when he leaves his car, he is the guy seen wandering around the South Shore with a Heathkit under his arm).

Breaker, breaker six . . . 10-4, good buddy.

Bandwidth Revisited

It appears that the FCC is at it again. The controversial "bandwidth" proposal, Docket 20777, has been shelved for the present time. FCC Chief Engineer Ray Spence indicated to *73* that a large amount of amateur interest has been generated by the proposed docket. This proposal would have, among other things, excluded AM from segments of the low bands and restricted bandwidth in the 420-450 spectrum to 35 kHz, thus banishing ATV as it now exists.

Spence indicated that a large amount of the comments were critical, especially those from the ATV enthusiasts. It was indicated that the FCC will develop another proposal concerning bandwidth; however, Spence said it would be "quite a while" before action is taken.

73 has received a considerable amount of input from interested hams concerning the bandwidth docket. Much, much more data is required, as we are being given a golden opportunity by the FCC to create our own proposal concerning bandwidth and the whole general topic of amateur radio deregulation. We at *73* are prepared to act as a clearinghouse for comments, proposals, and suggestions relating to amateur deregulation. The bandwidth question is presently the hot subject. However, please do not overlook other aspects of deregulation, such as repeater rules relaxation. (Refer to this month's "Briefs" in *73*.) Let's get going! Talk up deregulation and bandwidth proposals at club meetings and over the air — the ball is back in our hands. Organize your thoughts on paper, and send them to *73*.

A questionnaire is being prepared by the *73* staff concerning repeater coordination, deregulation, and bandwidth. This will initially be sent to those who originally commented on 20777. Repeater coordinators will also receive a form, as well as the clubs listed in our files. Any individual or club requesting a questionnaire should write *73*, marking the card or letter "Bandwidth Questionnaire."

In a few weeks (time is short), we will compile a proposal based upon your suggestions. This will appear in *73* and will aid us in our conversations with the FCC. Start planning!

Amateur Antidote

"Break . . . Emergency . . . ZP5NP." That distress call broke into what had been an ordinary day for amateur George B. Riley, who was on a QSO with several other hams in the Virgin Islands from his home in Linden NJ.

Riley, an engineering supervisor at WOR-TV in New York City, became a link in a communication chain to the Food and Drug Administration's National Clearinghouse for Poison Control Centers in Bethesda MD.

ZP5NP was Paraguayan Army Sargeant Nelson Guadalope, who was attempting to connect with any American ham who could reach proper medical authorities to aid in treating a six year old girl who had swallowed a chemical herbicide known as Tributon.

A local doctor had originally treated the girl for a severe cold. Only after she had become gravely ill had the doctor discovered that she had drunk the poison. The doctor needed information about the ingredients in Tributon and was unable to get it locally. So he turned to the U.S. for aid.

While still in contact with ZP5NP via another amateur in the Virgin Islands, Riley was able to contact the FDA's Division of Poison Control where pharmacist Larry Trissel had just reported for duty. Trissel consulted his index cards where products are listed alphabetically by brand or generic name. After some initial confusion over the spelling of the product, the ingredients and proper treatment were found.

Only about ten minutes had passed between Riley's original call to the hospital and the prescription of treatment. However, transmission difficulties delayed the relay of the information to Paraguay by almost an hour. Nevertheless, the information was received in time to save the girl's life.

Riley later received a letter from the U.S. ambassador thanking him for helping in the girl's recovery. Through Riley's efforts, amateur radio received valuable publicity.

Trevose Tower - Plus Eight

It was back in June of 1969 that Preston Funk had his famous tower built in his backyard at 4860 Magnolia Avenue in Trevose.

The tower is 229 feet tall. It has become a landmark in more ways than one in the nearly 7½ years since it was constructed.

It seems as though there have been as many hearings to decide what to do about the tower as there are feet in its height.

A neighbor of Funk's started a long list of complaints shortly after the tower was finished and Funk began using it for his "ham" radio operations.

The neighbor complained he was receiving radio signals from Funk's station over his home radio, television set, and telephone.

The Federal Communications Commission got into the proceedings. The FCC suggested a complaint also be filed with its office in Philadelphia. The FCC also told Funk's neighbor that a filter of the proper kind installed on the TV set would eliminate the interference.

20 Meetings

In the first year, there were more than 20 meetings held by Bensalem governing bodies in an attempt to clarify the situation. That number has doubled.

There are more than 90 stories in the files of the Bucks County *Courier Times* concerning the tower since it was completed around June 25, 1970.

On March 25, 1970, the Bensalem Township Zoning Hearing Board ordered Funk to take down his tower.

As anyone who has driven by the imposing structure lately can see, it still is there, poking its way into the sky.

In May of 1974, a Bucks County Court ruled against Funk's appeal in March, 1970, agreeing with the Bensalem zoners that the tower had to come down.

He followed his defeat in the Bucks court by appealing to the Commonwealth Court of Pennsylvania. In February of 1975, the state court, too, ruled the tower should come down.

Helping Victims

In between the two court rulings and appeals, Funk's ham radio station proved its worth.

When Hurricane Agnes brought the state's worst flood in June of 1972, hundreds of people made use of Funk's ham radio facilities to send messages to relatives in the flood-stricken areas.

Later, when earthquakes devastated Managua, Nicaragua, Funk again acted as a go-between for messages to and from the stricken area.

Meanwhile, new homes have gone

up on Magnolia Avenue. One of them is directly across the street from Funk's tower. Mr. and Mrs. Edward H. Kolb live there.

Mrs. Kolb said today, "We moved from Philadelphia about a year and a half ago. I see the tower every day. It's right across the street. But it doesn't bother me. And we haven't had any interference problems on our television or radio."

A few houses down the street, Charles W. Conley echoed Mrs. Kolb's remarks. "No, we haven't had any trouble, either. The tower doesn't bother me at all."

Hearing Rescheduled

Last night, the Bensalem Township Zoning Hearing Board scheduled another meeting to hear Funk's bid for a variance that would allow his tower to remain up, despite the adverse rulings by the courts.

This hearing was postponed from April, scheduled for May, when it was postponed again — until last night.

Two members of the board couldn't make the meeting. So, once again, a decision on Funk's tower has been put off.

On hand last night were a lawyer or two, a reporter, a couple of persons who had other business to transact with the zoning board, but no spectators.

It would appear Preston Funk and his tower have outlasted the opposition. After 7½ years, even Muhammad Ali would get weary of battling the same foe.

LF-Still Many Questions

Simultaneous observations by three satellites have confirmed that long waves in the earth's magnetic field, which spread the disruptive effects of magnetic storms on earth, are generated far out in space by energetic particles from the sun.

Drs. Joseph N. Barfield of the National Oceanic and Atmospheric Administration, R.L. McPherron of the University of California at Los Angeles, and W.J. Hughes of London's Imperial College, reported the results of their satellite measurements at the fall annual meeting of the American Geophysical Union in San Francisco early in December.

They found that the low frequency waves are generated by the solar wind, the constant stream of energetic particles that flows outward from the sun. When the solar wind strikes the magnetopause (the boundary where the earth's magnetic field loses its dominance and bows to the sun's), it generates waves in much the same way as wind does over water, according to Barfield. These waves travel earthward, enter a "resonant region" where they are amplified, and propagate down to the ground. In ways that are still poorly understood, they are involved in magnetic disturbances, which disrupt communication and power transmission on earth.

But they also have some pragmatic uses, in oil and mineral exploration. By monitoring the waves as they travel through different spots on earth, prospectors can learn something about the substructure, such as the location of ore bodies. Paradoxically, the waves may also aid communication. Since they penetrate the ocean, they may someday be used to communicate with submarines, which now have to surface to make contact.

Hughes, Barfield, and McPherron detected the waves from magnetometers aboard three satellites in synchronous orbit 22,200 miles (35,720 kilometers) above the earth, the first time several satellites had been used to make such measurements simultaneously. The environmental satellites SMS-1 and SMS-2, and ATS-6, a research satellite, are in a line along the earth's equator, each orbiting at a speed that keeps it poised above the same spot on earth. Hughes, Barfield, and McPherron used this satellite arrangement to determine the origin of the electromagnetic waves.

The magnetopause curves around the sunward side of the earth, with a "nose" pointing toward the sun. The three space scientists predicted that if the low frequency waves were generated at the "nose," as they believed, the first satellite to detect the descending wave front should be the one closest to the sun at the time. They found that the wave front did pass each satellite in the predicted order.

The satellite measurements also showed how the waves are amplified and propagated, according to Barfield, a researcher with NOAA's Space Environment Laboratory (one of the Commerce Department agency's Environmental Research Laboratories). Originally, it was thought that the lines of force of the earth's magnetic field would vibrate like a guitar string, setting up the waves.

Early ground-based observations also had suggested that as a wave generated at the magnetopause travels inward toward earth, its amplitude decreases until it reaches a certain altitude, a "resonance region," where it is amplified.

The three satellites are located right at this resonance region. "For the first time we could look at things right where they were happening, with multiple probes," Barfield said. Measurements from the satellites confirmed the existence of the resonance region by observing the change in amplitude of descending waves. The "guitar string" theory was not all wrong, but the waves do not originate at a magnetic field line; they are amplified there. "A wave travels earthward until it finds a magnetic field line that responds to the particular frequency of the wave," McPherron explained. This is the resonance region.

The scientists used the amplitude changes of the waves to infer some of the characteristics of the resonance region. By noting how changes in amplitude of the waves differ between the satellites, the researchers found that the resonance region is very narrow on a magnetospheric scale — about 750 miles (1,200 kilometers) thick.

The next step in the research, according to Barfield, is to look at the characteristics of the waves; what are the spatial limits of where these waves occur and how do they relate to local features of magnetic disturbances?

The scientists hope to study the wave frequencies to learn something about how matter is distributed along magnetic field lines. First, it is necessary to calibrate the waves—to learn what different wave characteristics perceived at earth reveal about what is going on farther out in space. For that, the satellites, with their direct measurements, are needed. But later, it may be possible to use the waves that reach earth to study the magnetic field thousands of miles above.

Louise A. Purrett
Boulder CO

On the Verge

The other day, listening on 75 meters, I came across a QSO that really jostled me. Two fellows were discussing the "sorry" state of ham radio. "All I do is work the same people, night after night," said one guy. His buddy replied that he "was having more fun on the way to work in the morning on the CB band." I've been listening to those two for years, and they never leave 75. Night after night the same QRM, the same dull conversation, and the same holding pattern.

It made me a little angry to hear them blaming ham radio for their fading interest. Neither of them (as near as I can tell) ever venture off 75, and until a year ago, they were running AM day and night, with the expected results. When the going got tough, they just kept on transmitting, carrier and all, trying to cover the 30 or 40 miles between them on a frequency filled with 9s and 5s. I guess it never occured to them to QSY to 10 or 15 when nighttime conditions on 75 got too rough. Or, how about VHF . . . couldn't they make it on 2 meter direct?

The real hangup these fellows seem to have is no interest in trying some of the other activities ham radio has to offer. Neither of them apparently realizes they could listen for OSCAR, and key a 2m HT to get into it. They probably never thought of running QRP, or trying 160m, either. And they both will probably continue until their dying gasps, squeaking out 50% QSOs on 75.

There has to be a way to save these guys. Otherwise they will be lost forever, just like those 64 thousand some odd satellite frequencies lost in the last WARC. Maybe we're too involved in pulling new amateurs into the fold, and are passing by hundreds of old-timers who've been buried in new technology.

When I think of all the things those two are missing out on, I feel kind of sad. It's the same feeling I have when I think of 19 CBers in the Baltimore-Washington area facing federal charges, because they tried the easy way into ham radio. The HFers, as they call themselves, may have the upper hand in numbers (when you consider the meager forces of the FCC). But sooner or later they will be caught, and I wonder how many Novice or other class amateurs will be among them.

The SSB outlaws and 75m hangers-on both have the same problem. Their collective lack of incentive must be a reflection of their lives. They stand on the verge of all ham radio has to offer, but take the easy way out . . . whether it be complacency or lawlessness. Think about it.

LETTERS

from page 111

ability of 30-50 MHz commercial equipment, I'd like to see more activity on this channel.

I've been monitoring 29.6 for the last 3 years, and I can tell you that 10 is open much more often than most hams believe. How about it OMs? More 29.6!

Michael R. Downing WB6OIM
Canoga Park CA 91306

A LITTLE PUSHING

I would like to take this opportunity to commend the author of "Hutchinson's Remedy," an article which appeared in the Holiday issue of this magazine. VE3CWY did an excellent job describing his cure to VFO chirp. The article was concise, explanatory, and interesting to read.

It seems this article could be a hit with those who don't like to use ICs and other solid state components, yet want to cure their home brewed VFO of chirp.

This is the type of article I believe will be popular among some *73* readers, who want practical applications for these new ICs, etc., to make them use them — I know I am one who needs a little pushing in this direction.

John Pilson WA1UZK
Saunderstown RI

INSPIRATION

I want to thank you for sending me your recent advertisement. It has inspired me anew.

For years now I have neglected my ham radio hobby, yet I continued to pursue studies of electronics which opened the door for a very rewarding career. I owe it all to a couple of "old hams" and publications such as yours for sparking a desire within me to want to know!

Now, more than ever before, I feel the need for promoting, practicing, and enjoying one of the most stimulating hobbies ever conceived. Perhaps I can spark that "want to know" in someone through ham radio and its many facets that have touched, changed, and made more rich our lives.

Keep up the good work and much luck to you in your efforts.

Kenneth R. (Randy) Lewis WB4NIH
Summerville SC

HELPING OUT

I am presently studying to get my Novice class license and your magazine and its articles are really helping me out. I've tried to read and understand *QST*, but find it very hard for someone who wants to become a ham. I know that your magazine can do a lot for someone who wants to become a ham.

Louis Zimmerman
Mexico City

THE ABOVE MENTIONED

Just thought I would drop a few lines and let you know how much I enjoy the construction articles in *73*. Just finished building K2OAW's 11C90 prescaler as well as the solid state subaudible encoder in your Dec. '76 issue.

I do wish that all your authors who go to the trouble to build PC boards for their construction articles would provide layouts for duplication such as the above mentioned did.

Although I do believe that microprocessors and such are the way of the future, I think the bulk of your I/O articles would be better suited for your new publication *Kilobaud* and not taking up space in an amateur publication.

Allen Jones K9DZE
Michigan City IN

QUICK, CLEAN HEAT

How come you don't have a regular Hints & Kinks column? Would seem to complement your "Circuits" section which I like so well.

Anyway, my idea that I'd like to share is keeping one of the throwaway butane cigarette lighters like the Cricket with my shrink tubing. It's a fine source of quick clean heat.

John Diebold W7SCU
Seattle WA

ANOTHER CHARTER

At it again, eh? Some people chase butterflies. Some collect stamps, others dabble in the stock market. And still others seek Billy Holliday Records.

But you! None of the above are good enough for you. Your hobby is starting magazines! No complaint, mind you. Just an observation.

I can't complain. As a *73* lifer and a (forgive me) charter *Byter*, I feel I'm ahead of the game. Add me to the list of charter subscribers to *Kilobaud*.

Social Events

MARSHALL MI
MAR 5

An unconventional Swap Fest will be held by the Southern Michigan Amateur Radio Society in conjunction with the Marshall High School Radio Club on Saturday, March 5, 1977 at the Marshall High School, Marshall, Michigan (near I-94 at I-69). Tech sessions, computer sessions, DX, VHF, YL meetings, plus a home tour of Historical Marshall, and dine at the world famous Win Schulers. Details and reservations: Goodrich, 117 Parrott Drive, Marshall, Michigan.

LAFAYETTE LA
MAR 5-6

The Lafayette Amateur Radio Club is holding its 17th Annual Hamfest and Banquet on March 5th and 6th. This event attracts hundreds of amateur radio operators throughout the south. For more information contact Lafayette Amateur Radio Club, 413 Kim Drive, Lafayette LA 70501.

STERLING IL
MAR 6

The Sterling-Rock Falls Amateur Radio Society Hamfest-77 will be held Sunday, March 6, 1977 at the Sterling High School Field House, 1608 4th Avenue, Sterling, Illinois. Free coffee and donuts 7:30-8:30 am. All indoor facilities and plenty of room. Plenty of parking area, including parking lot to accommodate campers and mobile trailers. First table free, second and third table $5.00 each. Limit three tables to a party or bring your own. Lots of prizes. For tickets and reservations for more than one table, write Don Van Sant WA9PBS, 1104 5th Avenue, Rock Falls IL 61071. Make checks payable to Sterling-Rock Falls Amateur Radio Society. Talk-in on 146.94 simplex. Advance tickets $1.50, door tickets $2.00.

PHOENIX AZ
MAR 6

The Winter Hamfest will be held March 6 at South Mountain Park at the south end of Central Avenue, Phoenix. Featuring swap meet, eyeball and pot luck. Sponsored by the Amateur Radio Council of Arizona.

BRIDGMAN MI
MAR 6

Blossomland Amateur Radio Association will hold the 11th Annual Spring Swap-Shop, Sunday, March 6th at Bridgman Middle School gym, Lake St. at Tower, Bridgman, Michigan. Exit 16 on I-94. Expanded facilities, refreshments, prizes, and fun. Talk-in on 22/82 and 94. Table space restricted to radio and electronic items only. Advance ticket donation $1.50. Tables $2. Write: John Sullivan, PO Box 345, St. Joseph MI 49085. Make checks payable to Blossomland A.R.A.

NORTH TONAWANDA NY
MAR 15

The Amateur Radio Association of the Tonawandas Annual Auction and Flea Mart will be held March 15th at 7 pm, at the Payne Avenue Christian Church, Payne Avenue, North Tonawanda, New York. Please tag all gear to be sold with seller's name or call, and minimum opening bid. If you have gear to sell please bring it. Admission free.

MAUMEE OH
MAR 20

The Toledo Mobile Radio Association, Inc. is sponsoring its 22nd Annual Ham Auction, Sunday, March 20, 1977 at the Lucas County Recreation Center, Maumee (Toledo), Ohio. Auction, flea market, commercial displays and good eyeball QSOs. Time: 8 am to 5 pm. Admission: $2 advance, $2.50 after March 1, 1977 or at the door. Talk-in on 52-52 and all Toledo area repeaters. Send SASE, Toledo Mobile Radio Association, Inc., Box 7548, Oregon OH 43616.

WHITEWATER WI
MAR 20

The Tri County ARC (Whitewater, Wisconsin) Hamfest will be held March 20, 1977 in the Whitewater Armory. Donation: $1.50 in advance, $2 at the door. Reserved tables $2 in advance. Write Doc Walters WB9EMR, 81 N. Main Street, Fort Atkinson WI 53538.

MIDLAND TX
MAR 26

The Midland Amateur Radio Club will have a Swap Fest on Saturday and Sunday, March 26th and 27th. It will be held in the County Exhibit Building on Highway 80, just East of Midland, Texas. Pre-registration will be $3.50 per person, and $4.00 at the door. Please send pre-registration fees to Midland Amateur Club, Box 4401, Midland TX 79701. There will be lots of door prizes.

EAST RUTHERFORD NJ
MAR 26

The Knight Raiders VHF Club presents its world famous Auction and Flea Market to be held at St. Joseph's Church in East Rutherford, New Jersey on Saturday, March 26, 1977. Free admission – free parking. Refreshments are available. Flea market tables: in advance – $5 for full table, or $3 for half table; at door – $6 for full table, or $3.50 for half table. For further information call Bob Kovaleski at 473-7113 (evenings only). Talk-in on 146.52. Send reservations and checks payable to Knight Raiders VHF Club, Inc., PO Box 1054, Passaic NJ 07055 (reservations close March 20).

CHARLOTTE NC
MAR 26-27

The 5th Annual Metrolina Hamfest will be held Saturday, March 26 from 12 pm to 6 pm, and Sunday, March 27 from 8 am to 4 pm. New location this year: North Carolina National Guard Armory, Douglas Municipal Airport, Charlotte NC. Door prizes: both Saturday and Sunday. Tickets: $3.00. Talk-in 34/94, W4BFB. For further information write: Mecklenburg Amateur Radio Society, 2425 Park Road, Charlotte NC 28209.

GRAND RAPIDS MI
APR 2

The Third Annual Swap and Shop will be held at the Northeast Jr. High School, 1400 Fuller Ave., N.E., Grand Rapids, Michigan, on Saturday, April 2 from 9 am to 5 pm in the cafeteria. Featured will be: CBs, monitors, ham equipment and electronic parts. For further information contact Grand Rapids React at the above address.

COLUMBUS GA
APR 2-3

The Columbus, Georgia Hamfest will be held April 2 and 3, Palm Sunday weekend, at the Fine Arts Building at Fairgrounds, 9 am to 4 pm daily. Flea market, ham auction, prize drawing at 1:30 pm Sunday, talk-in 28/88, 3975 kHz, buffet dinner Sat. at 8 pm. For more information write K4JNL. Advance tickets: K3MTY/4, Rt 5, Box 750, Phenix City AL 36867.

ST. CLAIR SHORES MI
APR 3

The South Eastern Michigan Amateur Radio Association is holding its Nineteenth Annual Hamfest on April 3, 1977 from 8 am EST to 3 pm EST. It will be held at the South Lake High School in St. Clair Shores, Michigan, 21900 Nine Mile Road and Mack Avenue. For further information contact Dorothy Spilski WB8PRJ, Secretary S.E.M.A.R.A., 11906 Riad Avenue, Detroit, Michigan 48224, 313-521-6646.

MOBILE AL
APR 16-17

The Mobile Amateur Radio Club will hold its annual Ham Fest and Computer Fest on April 16 and 17th – all the newest equipment on display, computers too. Swap & Shop all day Saturday from 9 to 5, banquet at 7 pm, doors open Sunday at 9 am, prizes, drawing at 1 pm. Activities for the ladies and children, campsites available, over 1500 people expected, the biggest Fest on the Gulf Coast. For more information contact Marvin Uphaus K4BVG, 512 Tuttle Avenue, Mobile AL 36604.

LIBERTY MO
APR 23-24

The P.H.D. Amateur Radio Assn., Inc., of Liberty MO (Kansas City area) will sponsor the Eighth Annual Northwest Missouri Hamfest on Saturday and Sunday, April 23 and 24, 1977 at the Kansas City Trade Mart, Exhibit Hall 2 (Municipal Airport terminal building). There will be a complete program of forums both days, a large

number of commercial exhibits, swap tables, YL-XYL program. Doors open from noon to 6 pm on Saturday, April 23; and from 9 am to 5 pm on Sunday, April 24. Setup time for commercial and swappers will be from 10 am to noon on Saturday. There will be a Saturday night banquet at the world famous Gold Buffet, with ARRL president Harry Dannals W2HD, as guest speaker. Pre-registration is $2, admission at the door will be $2.50. Pre-registration including banquet is $8. Talk-in on 146.34/.94 and 3.925 MHz. For information and pre-registration write to: PHD Amateur Radio Assn., PO Box 11, Liberty MO 64068.

SULLIVAN IL
APR 24

The Moultrie Amateur Radio Klub will have its 16th Annual Hamfest Sunday, April 24th at Wyman Park, Sullivan, Illinois. Heated indoor area and large outdoor parking area. No charge to vendors. For information write: MARK Radio Klub, PO Box 327, Mattoon IL 61938. Talk-in 146.94.

AMBOY IL
APR 24

The Rock River Radio Club Hamfest will be held April 24, 1977 at Amboy, Illinois (Lee County), at the 4H Center, Routes 30 and 52. Same place as last year. Tickets $1.00 advance. $2.00 at gate. Camper parking available at a nominal fee. Write: Carl Karlson W9ECF, Nachusa IL 61057. Indoor and outdoor facilities.

LAS CRUCES NM
APR 24

The Mesilla Valley Radio Club sponsors Whitey's Bean Feed and Swap-Fest Sunday, April 24th, at 10 am. Located near Las Cruces, New Mexico at La Mesa with talk-ins on 16-76, 04-64 and 3940 kHz. Fun for all the family with big prizes, plenty of food and the usual beverage truck. All included for $5.00 for adults, $1.75 for kids. Eat, drink and win a prize with Whitey K5ECQ as host. Free overnight parking at grounds so come for a spell. All correspondence should be made to: Thomas B. Rapkock Jr., 640 W. Las Cruces Avenue, Las Cruces NM 88001.

DAYTON OH
APR 29

The 8th Annual FM B*A*S*H will be held on the Friday night of Dayton Hamvention, April 29, 1977, at the Dayton Biltmore Towers (hotel), Main at First Streets, from 8 pm til midnight. Admission is free to all hams and their friends. Sandwiches, beverages, snacks and C.O.D. bar will be available. A live floor show will be presented by TV personality Rob Reider WA8GFF and his group. It will be followed at 11 pm by a fabulous prize drawing featuring an Icom IC-245 and many others. See you where the action is!

MEADVILLE PA
MAY 7

The Third Annual Northwestern Pennsylvania Hamfest will be held May 7 at Crawford County Fairgrounds, Meadville PA. Free admission. Flea market begins at 10 am. $2 to display — hourly door prizes — refreshments — commercial displays welcome. Indoors if rain. Talk-in 146.04/64 and 146.52. Details C.A.R.S., PO Box 653, Meadville PA 16335.

BINGHAMTON NY
MAY 7

The 18th Annual STARC Hamfest will be held Saturday, May 7, 1977 at Binghamton, New York. Take exit 71N from NY-17, go 3.8 miles north on Stella-Ireland Road. Flea market, tech talks, hourly door prizes. General admission $2.00/person. Banquet by pre-reservation at $6.00/person. Indoor exhibit space by pre-registration at $5.00 per table. Outdoor exhibit flea market space free. Talk-in 146.22/82 and 94/94. For details and reservations, contact STARC, PO Box 11, Endicott NY 13760.

NEW YORK NY
JUN 12

The 4th Annual Hall of Science A.R.C. Flea Market and Hamvention. Dealers booths, test bench, refreshments, zoo, museum. A fun day for the whole family. Sunday, June 12 (rain date June 19), 9 am to 3 pm. Admission: $2.00. Free parking. Directions: .34/.94 repeater; information: (212) 699-9400.

PLAIN CITY OH
AUG 14

Hamfest 77 is to be held on Sunday, August 14, 1977 at the Plain City Fairgrounds, Plain City OH. Talk-in on 146.16/76 or 146.52. Advance tickets $1.50 — gate $2.00. For additional information or reservations, write UCARC, 13613 U.S. 36, Marysville OH 43040, or call Gene Kirby W8BJN 513-642-9861.

ERIE PA
AUG 27

The 2nd Annual Erie Ham Jam will be held Saturday, August 27, 1977 at the Erie County Fieldhouse, Route 8 (Parade Street) and I-90. Flea Market — large indoor display area — forums — camping and motels nearby. For more information contact RAE Ham Jam, Box 844, Erie PA 16512.

MADISON WI
SEPT 25

The 5th Annual Madison Swapfest will be held Sunday, September 25 at Dane Co. Expo Center Youth Building, Madison WI. Rain or shine — inside facilities — doors open at 8 am. 12,000 sq. ft. of electronic equipment and components for hams, computer hobbyists and experimenters. Bring the whole family for delicious food and entertainment. Excellent overnite camping accommodations. Tickets — advanced $1.50; at door $2.00. Tables — advanced $2.00; at door $3.00. Make check or money order payable to M.A.R.A. — mail to M.A.R.A., Box 3403, Madison WI 53704. Reservations must be in by Sept. 10, 1977.

Ham Help

Let me congratulate you for the progress that the *73 Magazine* has made. You have struck me with lightning three times. My son Gurbux Singh at Rochester (WB9TTN) will take care to ground the electrical buildup. I have passed your *73* to a lot of people and it has been a pastime with me to read over and over again some of the articles. Your September issue arrived yesterday and was wonderful. You made history and let me congratulate Sherry Smythe for the wonderful photographs.

Wayne . . . could you put me on "Wanted Help" column? We need radio magazines and other reading matter. Please do not send any equipment for amateur radio is still under suspension. Our license is however renewed.

Let me wish you more success and when are we two going to have an eyeball QSO? 73 to *73*.

Tara Singh
XZ2KN and XZ2TA (mobile)
187 Eden St.
Rangoon, Burma

I am interested in getting my ham ticket. Please enter my name and address in your Ham Help column. Thank you.

Norman Malinky
405 W. Walnut St.
Painesville OH 44077
216-352-4162

I am in the service, and in Germany, C8 is going to the birds more than ever. I'm enclosing my order for your set of *73* tapes, and will need help pretty soon. I've heard that the Conditional class license is no longer available. How can I get my license if this is true? I'm stationed in Augsburg and hope there is a ham nearby. I've even gone to the extent of getting a credit account with SWAN.

SP5 Tim Y. Woo
483d Med. Det. (Vet Svc)
Augsburg, FRG

I am trying to get into the CW world, but only have old equipment, some working, some not. I need the following: (1) instructions (literature) for Lysco, mod. 600 xmtr; (2) i-f can, coils (parts) for Hammarlund mod. HQ-110 receiver.

I'll be glad to send $1.00 for postage to the first ham to help me out.

Dale McMindes PJ4DM
T.W.R. Box 37
Bonaire,
Netherlands Antilles

I badly need the schematic and owner's manual for the HQ-100 general coverage receiver.

Robert M. Johnson
36 Wolcott St.
Camden NY 13316

I read the article in the December issue about the Friden-8800 problem, and since that time I have acquired one of these things. I was quite wary for a while, as if something went awry with the electronics, I would be up the creek. The only thing that the vendor supplied was the operational manual, which tells you how to change the ribbon, etc.

Well, after much hunting, I was able to locate some more information on the thing, and I am sure that others will be glad to hear of it. I have schematics of printed circuit boards, with interconnecting wiring data, power supply schematics, and all other data which will help anyone in solving logic problems within the unit. I am offering these copies at $6.00, which includes shipping. This is done mostly on a cost basis and shipping.

Tim Ahrens WA5VQK/5
2200 Sorret Tree Ct.
Austin TX 78744

You are my last hope. Can you please put my letter in your Ham Help column? I subscribe to your magazine and reading the article on those hams in Weisbaden (Oct., 76), I tried to contact them! No answer. If you have any info that can help me, that would be great!

I am looking for an American ham who is stationed or living in Germany and is licensed to operate in that country who can help me get my license over here. I am a special radio and electronic devices repairman for the Army. On my last leave, I didn't have enough time to get my ticket. I've been trying feverishly for a year and all my leads have been dead ends. I still have 3 years over here! PLEASE HELP ME!!! Anyone.

APO NY 09139

Anyone know how to improve the receiver section of the Swan 350?

Is there such an animal as a wideband low gain preselector? This circuit would have to be inserted between the antenna relay and the rf amp tube of the receiver section and be capable of covering 80 through 10 meters. I would like a small circuit which could be mounted inside the transceiver housing.

Thank you.

Lloyd Gosa WB8TNC
1423 Upland Dr.
Kalamazoo MI 49001

I have obtained a set of wiring diagrams (45 sheets) for the Friden TM20K715 and TM20K714 printer and controller, and I am interested in sharing the information. The cost would depend on how many people are interested and, hopefully, if enough people want copies, the cost would be about $35.00.

The listed data tells you the time and place OSCAR crosses the equator in an ascending orbit for the first time each day. To calculate successive orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the first crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world, it will descend over you. To find the equatorial descending longitude, subtract 166 degrees from the ascending longitude. To find the time it passes the north pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR when it is within 45 degrees of you. The easiest way to do this is to take a globe and draw a circle with a radius of 2480 miles (4000 kilometers) from the home QTH. If it passes right overhead, you should be able to hear it for about 24 minutes total. OSCAR will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15 degrees from you, add another minute; at 30 degrees, three minutes; at 45 degrees, ten minutes.

OSCAR 6: Input 145.90-146.00 MHz; Output 29.45-29.55 MHz; Telemetry beacon at 29.45 MHz. OSCAR 7 Mode A: Input 145.85-145.95 MHz; Output 29.40-29.50 MHz. Mode B: Input 432.125-432.175 MHz; Output 145.925-145.975 MHz.

Orbits designated "X" are closed to general use. "ED" are for educational use. "BTN" orbits contain news bulletins. "Q" orbits have a ten Watt erp limit. "L" indicates link orbit. "N" or "S" indicates that Oscar 6 is available *only* on northbound or southbound passes. Satellites are not available to users on "NA" days.

Review

AUDIO FREQUENCY TESTERS
The 73 Test Equipment Library, Published by 73, Inc., $4.95

This book, the second in the *73* series on test equipment for the radio amateur and experimenter, approaches the subject of audio frequency testing from every angle.

It is appropriate that this second book in this series be devoted to audio frequency test equipment, since this area plays such a large part in so many facets of amateur radio. From voice transmission (SSB, FM or AM) to ham TV, the precise measurement and generation of audio frequencies is essential to the testing and operation of all equipment. For the RTTY operator, whether he uses AFSK or FSK, this book should be invaluable for the proper maintenance of his station.

Through the 39 separate articles, the reader is instructed on how to build such items as audio sine wave generators, attenuators, two-tone generators for SSB testing, tone generators for RTTY, RTTY monitorscopes, SSTV and FSTV sync generators, oscilloscopes, and more.

No complete ham shack or workshop should be without a copy. There is no better source available on the subject for so reasonable a price or with such clear, concise easy-to-build projects.

Associate Editor

RADIO FREQUENCY TESTERS
The 73 Test Equipment Library, Published by 73, Inc., $4.95

The generation of radio frequency waves is the one common denominator throughout all of ham radio. No matter what your specific interest in this fascinating hobby, without the correct generation and radiation of radio waves your enjoyment will be frustrated. In this book, which is the third in the *73* Test Equipment Library series, the editors of *73* have put together some of the best articles they could find, all aimed at assisting in achieving the best possible on-the-air signal.

With the inclusion of 77 articles, the book covers such subjects as swr measurement, rf impedance measurement, rf power measurement, field strength, frequency measurement, rf signal generators, crystal calibrators, grid dip oscillators, noise generators, attenuators, dummy loads, and more. Each subject is illustrated with various pieces of equipment which can be built to fit your specific needs.

By addition of this book to a station library, any ham can be well on his way to having one of the best signals on the band.

HOW TO MAKE BETTER QSLS
by Jack Janicke K2JFJ, Published by 73, Inc., $4.95

Jack Janicke in his new book published by *73* appeals to the artistically minded ham by guiding him on his way to making original unique QSL cards. Janicke contends, and it is true, that the "special" QSL is the one that gets answered first by DX stations. One chapter is devoted entirely to boosting QSL returns.

All types of printing processes are included, with special emphasis being placed on the silk screen method. Plans and pictures are included to allow the reader to construct, with the utmost ease, the necessary equipment for silk screening QSLs, as well as other items found around the normal ham station. Many other uses for the silk screen materials are explored.

This book should also appeal to the beginning art student, who is just starting into silk screening. All silk screen techniques are thoroughly covered.

In addition to silk screen, the methods for producing photographic, mimeograph, and letterpress cards are also examined. Janicke goes into detail on each.

So if the high cost of having "unique" QSLs has you down, try rolling your own, but first learn how from an expert in the book, "How to Make Better QSLs."

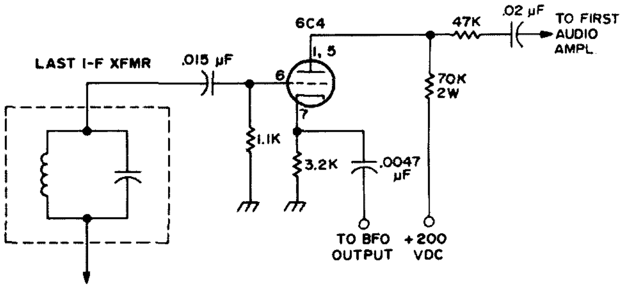
DIGITAL INTEGRATED-CIRCUIT OPERATIONAL-AMPLIFIER AND OPTOELECTRONIC CIRCUIT DESIGN
Texas Instruments Electronics Series, Published by McGraw-Hill Book Company, $16.50

If microprocessor design and interface techniques are your thing, Texas Instruments has the reference book you have been needing. More than just a collection of IC specifications and pinouts, "Digital Integrated-Circuit, Operational-Amplifier, and Optoelectronic Circuit Design" provides practical circuits and applications using the devices specified in the title. Eighteen chapters cover an entire range of devices, from introductory TTL and Schottky logic, counters, and converters, all the way to optoelectronic devices used in computer interfaces. If you have ever puzzled for hours over a tiny aspect of circuit design, the answer to your problem may rest in this book, a necessary addition to any computer hardware enthusiast's library.

John Molnar WB2ZCF
73 Magazine Staff

Novice Q&A

This column will be a monthly feature of 73 Magazine. It is hoped that it will be of assistance to beginners and old-timers alike. We only ask that your questions be kept as general as possible. We will try to answer all queries received. Please mail your questions to Technical Editor, 73 Magazine, Peterborough NH 03458.

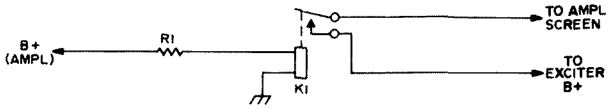


Q. Is there a practical SSB detector for most receivers?

A. The circuit in the figure is simple, but will not disturb the set. Your regular detector can be switched in or out and the simple detector used, or not. A stable bfo signal is required. This circuit will work with older receivers when the voltage to the bfo tube is stabilized.

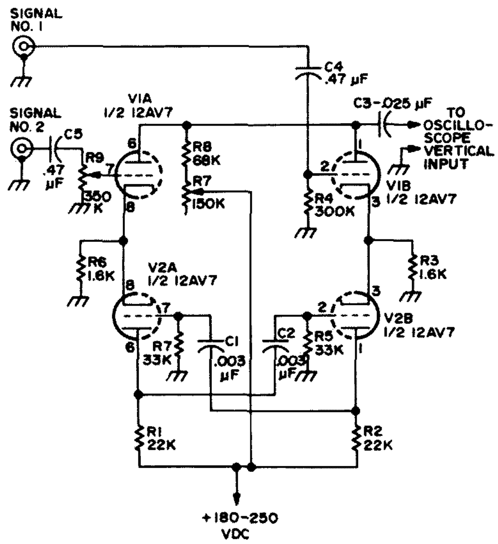
Q. What frequent check should be made of self-powered VTVMs?

A. From time to time the VTVM should be opened and the battery examined. It should be firmly seated in the holder and the battery contacts should not be corroded. Check the tightness of all bracket held-down screws. If you cannot zero-set the VTVM, replace the battery.



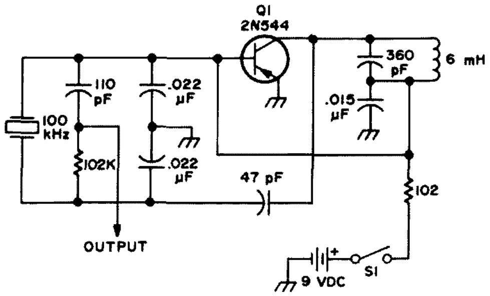
Q. How can amplifier screen voltage be removed during periods when the transmitter is operated with the final plate supply turned off?

A. The circuit in the figure permits safe operation of the amplifier screen-grid circuit when powered by the exciter supply. K1's coil is connected in series with the bleeder resistor (R1) for the amplifier's plate supply. Contacts are connected in series, with the lead running from the exciter supply to the amplifier screen circuit. In this manner, screen voltage is only applied to the final when the HV supply is turned on. Common 5k to 10k relays can be used. The value of R1 must be chosen for satisfactory bleeder operation plus an appropriate drop in B plus for the relay coil.



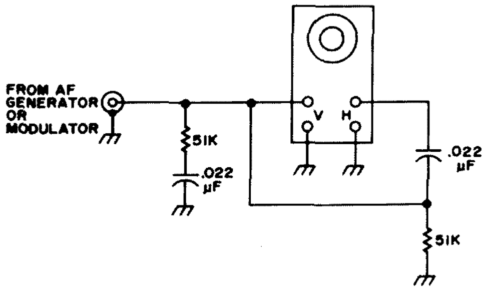
Q. Is it possible to see two signals simultaneously presented on a CRT screen by using a special type of electronic switch?

A. Refer to the figure. Two signals are alternately switched to one input of the scope so rapidly that you seem to "see" two presentations. But actually there is only one signal shown at a given time on the screen. This is a handy gadget for checking input and output waveforms.



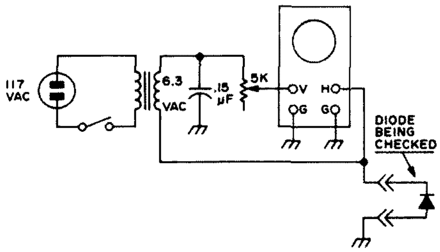
Q. How about a simple transistor 100 kHz calibrator for my ham band transceiver?

A. Refer to the figure. The output of this simple crystal calibrator should be connected at the receiver's antenna input side — not at the antenna terminal you would normally use.



Q. To get an elliptical pattern from an af generator, what is the proper method for connecting the scope?

A. Refer to the figure. Modulation can be added to the Lissajous pattern either on a vertical or horizontal form.



Q. Is there a simple scope setup to make it easy to check and match diodes?

A. When checking diodes of the same type, with the circuit in the figure, a comparison can be obtained by utilizing the same pot setting and noting the relative sizes of the traces obtained. Choice of a transformer is not critical. In addition to scope conventional traces, look for any indication of "fuzz" or ripple. Even if the basic trace seems good, do not rely on a diode exhibiting either fuzz or ripple.

Q. How can a transmitter be easily modified for CW operation?

A. By feeding an af oscillator into the mike jack, a transmitter can be used for CW operation. The oscillator can also feed a pair of phones for sidetone monitoring. The output of the keyed oscillator should be a good clean sine wave and care should be taken that the modulator is not overdriven.

Q. What causes the exciter meter to deflect to the left when the transmitter is on and the PTT is actuated?

A. A diode in the metering circuit may develop a reverse leakage which will permit some of the positive delay bias to appear in the exciter alc circuit. This causes down-scale deflection of the meter. To correct the condition, simply replace the diode with one which has a much higher voltage rating and it will block the delay bias completely.

Q. Regarding batteries: When should a mercury or a manganese battery be used?

A. Where long shelf life, steady output voltage and size are important, the mercury battery should be used. The manganese battery should be used only when you need both high surge capability and good shelf life. Both batteries are far superior to the old lead-zinc cells. Although more costly, the newer batteries are worth the price difference.

News? We need input, and one of the best sources is the club newsletter. Got one? We reiterate our longstanding offer of a free subscription to 73 or Kilobaud in exchange for a spot on your ham or computer club newsletter mailing list. Deal?

Briefs

from page 21

Amateur Radio Club, will be sponsoring an AMSAT net on one of the club repeaters, WR2ADM–146.25/85, at 2000 hours local time, each Wednesday. The net will be educational as well as conversational with exchanges of information between net members. The basic objective of the net is to get complete operating information to new and potential OSCAR users.

In the near future, the net will also operate on 2m sideband at 145.70. Stations who are not located in the immediate area should aim their antennas toward Bellmore, L.I., located in Southcentral Nassau County. Net control is Hank WB2ALW with assistance from Barry WA2BOP. Thanks to WB2ALW.

Duane Hill of Peoria, Illinois, is the first new radio amateur in the United States to qualify for a special Bonus Award offered by Yaesu Electronics Corporation of Paramount, California.

Mr. Hill, who received his amateur license call letters, WB9YNQ, last month, entered amateur radio as a hobby for the first time last month. After purchasing a new Yaesu FT-221 two meter transceiver from Klaus Radio, Inc., in Peoria, he received a $25 bonus gift from Yaesu and was also reimbursed for the $4 license fee paid to the Federal Communications Commission.

Amateur radio operators offer many worthwhile services to their communities and the nation. Yaesu Electronics Corporation instituted its award plan as an added incentive to encourage shortwave listeners, CBers, and others to expand their interests into such services while being able to converse worldwide.

The idea of a 2 meter SSB DX contest proposed and promoted by Yaesu Electronics Corporation has been put to rest by the FCC. Yaesu had planned a one month contest in April that was to have offered thousands of dollars of prizes.

When the company approached the FCC field office in Los Angeles several months ago, they were told that officials there saw "nothing wrong with the idea." On that basis, Yaesu began to develop the contest. Early in December, they wrote to the FCC in Washington asking that the verbal approval be confirmed in writing. Nearly a month later, after receiving no reply from Washington, Yaesu National Sales Manager Glenn Malme W6OJF called the FCC and was told by a high-placed official that the contest would have to be cancelled because it was "wrong to give monetary reward to amateurs for doing what they normally do."

Yaesu immediately sent a memo to all dealers cancelling the contest and attempted to pull ads from ham magazines. Because *CQ* went to press early, the ad will appear in that magazine.

The contest was to have been run and results verified by the nationwide network of Yaesu dealers. Malme told *73* that the company was disappointed because of the large investment in advertising and printing. He said that, "Possibly the idea is to qualify hams for sainthood after they become silent keys."

Allied Electronics is offering its *1977 Engineering Manual and Purchasing Guide* to *73* readers free! The book lists hundreds of parts: industrial type electronic parts, components, supplies, and equipment. The 1977 edition uses metric measurements on many listings for the first time. There's wire, cable, solid state devices, test equipment, resistors, trimmers and potentiometers, transformers, switches, timers, connectors, relays, tools, capacitors, new solar energy products, and even a microprocessor. In all, 212 pages . . . and free for the asking. Write Allied Electronics, Dept. 77-F, 401 East 8th Street, Fort Worth TX 76102.

Genave is modifying GTX-202s at its own cost, after "the advertising department got ahead of the production department." A letter from Genave Executive Vice President Claude Henderson WA9CQS went to all customers: "We goofed. Our Advertising Department got ahead of our Production Department on the GTX-202, and we advertised some features which had not yet been incorporated in the rig. If you return your rig to us, we'll rapidly modify and update it for you. P.S. We'd like to give you a set of rocks to offset this inconvenience. Please specify your choice, and if they're in stock, we'll install them while we have your rig." An internal memo released to *73* warned employees at Genave: "Let us not goof again by losing radios, charging for crystals, or taking three weeks or longer to turn these radios around." Need we say more?

In the best ham tradition, Art Householder K9TRG, president of Spectronics in Oak Park, Illinois, left the hospital and proceeded directly to the store after suffering a stroke on December 28. In a discussion with Mr. John Perry of Spectronics, it was indicated that Art "will not be kept down" and is ready to return to work. However, he is suffering from slight paralysis of the left leg and requires a crutch to move around the shop.

An 800 channel hand-held? It's about to become reality. As soon as FCC certification is granted, Wilson Electronics will start marketing the WE800 synthesized 2 meter portable. The rig weighs two pounds, measures 8 ¼" by 6 ¾" by 1 7/8", and features an internal nicad pack that gives output power of 2 Watts. With external dc, power jumps to 12 Watts. The CMOS synthesizer circuit features low drain and covers 144-148 MHz in 5 kHz steps. The price has not yet been announced.

Wilson has also announced a line of crank-up towers: the 64 foot SST-64 guyed four section, the TT-45 free standing two section, and the GT-46 46 foot economy tower. They are priced from $219 to $375.

The new Wilson WR1000 rotor is the largest amateur unit on the market, capable of turning over one ton of balanced weight. Suggested list is $429.00.

The Barnstable MA Amateur Radio Club, located on Cape Cod, is currently raising funds for a station to commemorate the 75th anniversary of Guglielmo Marconi's feat of the first two way radio transmission between the United States and Europe. The original rotary spark gap station was located in South Wellfleet MA. The historic transmission took place on January 18, 1903.

The club plans an all band operation that should be ready for tests by this year's field day. Amateurs in England are setting up their own station.

Commemorative envelopes are being sold at ten for $1.50. Contributions can be sent to the station's trustee, R.J. Doherty W1GDB, RFD #1 14 Pine St., Sandwich MA 02563.

The Rochester NY hamfest, largest in the northeast, continues to grow. The 1977 event, to be held May 20-22, will be three days long. The program will be mailed to nearly 10,000 people who have attended in recent years. Plans call for a Friday afternoon flea market to continue through the weekend outdoors, with an indoor flea market open at the same time. Exhibitors will be set up all day Saturday and Sunday in the Rochester Dome Center.
RaRa Rag, *bulletin of the Rochester Amateur Radio Association.*

Normally most of us think of safety in the ham shack as watching out for high voltages inside of equipment, or determining its potential points of appearance at unplanned places due to possible component failure. In this particular instance, this is not the case. We are considering safety with regards to the mobile ham shack, with safety of the shack of prime importance. How many times have you missed your turn-off because you were too engrossed in a QSO? We all probably have at one time or another. Good thing there wasn't anyone in the way at the time or we might not have "seen" them!

Besides paying attention to the driving (it might be better to leave the driving to someone else), you need a good mounting location for your rig, being sure it is stable (i.e., it won't fall on the floor), and within a comfortable reach of the normal driving position.

A channel switching knob shaped so you don't have to look to find the frequency, and can go by feel, is highly recommended.

A touchtone pad is even more difficult to operate if you need two hands (who's steering now?!). It's best under these conditions to pull off the road completely to make the autopatch call. If a call is that important, it's worth stopping for.

So, in conclusion, use common sense and keep the mobile shack and its contents alive. We know of one CARA member who was distracted by his rig falling off his front seat, managed to take a half inch off a telephone pole and about $700 out of the right side of his car, breaking a $3 connector on the rig. So keep your priorities straight!
Reprinted from QRZ, *bulletin of the Middlesex (MA) Amateur Radio Club.*

Those of you scratching your heads over similarities between the October *73* article, "The Hybrid Quad," and "A Hybrid 20 Meter Quad" in January, '77 *QST*, scratch no more . . . they are in fact the same article by the same author. A letter from League headquarters apologized for the error, pointing out that the author had submitted his article to both magazines at the same time. A word to the wise . . .

At deadline, FCC sources told *73* that the WARC comments deadline on the third notice of allocation proposals (see Special Report, February) had been extended to February 7th, with a reply comments limit of February 25th. A petition from the National Association of Broadcasters (NAB) for a 90 day extension was reportedly the reason for the new dates. On the allocations front, our sources say that there is some hope for improvement at the HF level, namely in the 10 MHz range. Chances appear good for a 200 kHz sharing arrangement with fixed services at 10 MHz, based upon the lack of usage there. Incidentally, of our assessment "The WARC Disaster" on the February cover, more than one FCC official said it was *reasonably accurate*, considering the WARC situation.

Broadcasts from station WWV in Fort Collins CO were terminated on 20 and 25 MHz on February 1st. It had earlier been reported that broadcasts on 2.52 and 5 MHz were to also be discontinued, but John Milton, WWV Engineer in Charge, told *73* that the decision was made to retain the frequencies after comments from users indicated a heavier use than had been estimated.

Congratulations to the publishers of the *West Coast DX Bulletin*, located at 77 Coleman Drive in San Rafael CA. This informative weekly newsletter on DXpeditions and DX conditions has passed the 1600 mark in circulation.

Buffalo's Worst Winter

Paragraph A of the FCC Rules and Regulations part 97.1 says that one of the fundamental purposes of the amateur radio service is "Recognition and enhancement of the value of the amateur service to the public as a voluntary non-commercial communication service, particularly with respect to providing emergency communications."

During the snow disaster in Buffalo NY at the end of January, amateurs proved their worth by taking over the job of emergency coordination of medical, food, and fuel supplies to the stricken city. The WR2ABU 31/91 repeater located in Buffalo was the focal point organized at the outset of the snow emergency on January 28. Repeater director Gilbert Boelke W2EUP, in a *73* interview, said that the week before the blizzard, the group had installed an emergency power system at the site. The new system received a test when it kept the repeater on at reduced power during four extended power failures. In another coincidence, the simulated emergency test scheduled for that weekend turned into the real thing.

Two other repeaters of the Buffalo Amateur Repeater Association were also used for coordination during the emergency: WR2ADR on 13/73 and WR2ACA on 40/00. WR2ACA is powered completely by a wind-driven generator. Gusts of up to 65 miles per hour during the blizzard kept it going at full capacity.

W2EUP said that over a hundred Buffalo area hams were involved in the emergency net, many of them on the air for over twenty hours a day. In the worst winter in the Buffalo area in 80 years, the area received over fifteen feet of snow in a three week period, prompting the city's 56 year old weatherman to give up and take early retirement. Driving in the downtown area was banned for over two weeks, and delivery of emergency supplies was undertaken by snowmobile.

Last fall, the Buffalo Amateur Repeater Association joined the local CB REACT group (Radio Emergency Associated Citizens Band Teams) in a cooperative effort aimed at keeping area motorists informed of traffic emergencies. The idea was the brainchild of a group of amateurs employed by radio station WBEN in Buffalo. The station received permission from the FCC to tape and rebroadcast repeater transmissions. They set up an emergency control center in the studio building. At the center, members of the REACT group and amateurs continually monitor CB channels and repeaters. When a traffic accident or hazard is reported, the message is immediately relayed to the announcer on duty via a video terminal. The police are also notified. Tapes of amateur transmissions are used when time and the situation warrants.

WBEN technical director Jerry Klebunde said he's happy with the results of the setup and feels that the station has been successful in reaching motorists without the capability of receiving hazard reports via amateur or CB radio.

The Ban Moves Closer

Drastic changes are in the works concerning the way amateur equipment is manufactured and sold. At deadline, the FCC was releasing two notices of proposed rule making that would make a 180 degree turn-about in the current trend towards deregulation. At issue is the plague of interference complaints (see "C'mone Texas Salt Rat" in guest editorials, March, '77) and unprecedented pressures on the FCC to do something to stop it.

One of the dockets would completely ban the manufacture and sale of linear amplifiers that operate in the 24 through 35 MHz range. It is a direct result of widespread violations of the CB power limit, use of amateur equipment out of band by CBers, and the use of broadband amps made only for the CB market under the guise of 80 through 10 meter coverage. (Input power required by the bogus amps is usually only 4 Watts.) Many of the so-called "black boxes," when tested in the FCC lab, showed incredible amounts of spurs. Several makes actually couple raw ac into the power meter circuit, in an attempt to raise indicated output!

The FCC has tried several approaches to slow down the distribution and use of the illegal amps, but the complaints have only intensified. That leaves the Commission with little choice: Unable to control their use, the FCC has decided to turn off the pipeline. In throwing the switch, however, amateurs everywhere will begin to feel the pinch.

No matter who you talk to, there is strong feeling at the FCC that they don't want to hurt the amateur. But the bottom line, in face of growing political pressure to do something about interference, is that the situation leaves the FCC no choice – limits on linears and type acceptance of *all* amateur equipment are soon to be reality.

There are some loopholes in the FCC proposals. For one thing, home brewing will be allowed for. The linear ban proposes that any licensed amateur may build *one* linear amplifier covering 24-35 MHz for use at a licensed amateur station. The linear can then be sold, but only to another licensed amateur. Here again, the FCC appears to be relying on the amateur community's long standing ability to be self-policing in terms of enforcement.

The second proposal will have an even greater impact on amateur radio as we know it. The FCC wants to make all amateur transmitting equipment and amplifiers subject to type acceptance. The proposed guidelines would roughly follow the same specifications applied to the land mobile service. The means the formula 43 + $10_{\log}$ of mean power is used to determine the permissible level of spurs. For a 10 Watt transmitter, spurs would have to be 53 dB below the output. For a 100 Watt rig, 63 dB; 73 dB for a 1000 Watt transmitter. This, in effect, puts a 50 uW limit on spurs at 100 Watts output. To put it another way, at the 53 dB figure, it would take nearly *two million* Watts for the spurs to equal 10 Watts. As for home brewing, the FCC proposal would allow any licensed amateur to modify commercial equipment, or build his own, which would not be subject to specs.

The reaction to all this was slow in coming at deadline. One of the first groups to react was ARMA, the newly formed Amateur Radio Manufacturer's Association. ARMA had attempted to derail the linear ban (see guest editorials, March, '77), but succeeded only in delaying it. Comments on the proposal will undoubtedly push for alternative methods of limiting illegal use of amplifiers and amateur equipment, but the FCC seems most reluctant to consider anything but a blanket ban. As ARMA spokesman Dennis Had of Dentron Radio put it in a *73* interview, "We have an incredible task ahead of us . . . first there is the need for our comments on the proposals . . . and then counterproposals. There is also the problem of existing production runs, and how to decide when the new measures must take effect." Had estimates that if type acceptance becomes law, it will up the cost of commercial equipment somewhere between $150 and $300 per rig.

There is strong feeling among manufacturers and amateurs alike that the amateur community is being made to pay for the past mistakes of both the FCC and "black box" manufacturers. Our hobby, they point out, has never been fully represented in Washington, because of the ARRL's tax exempt status (which prevents the League from being an effective lobby). ARMA is representing us now, but is facing off against some of the most powerful "money" lobbies in Washington – the broadcasters (who share an attorney with the ARRL) and the TV manufacturers.

The NAB (National Association of Broadcasters), represented by ARRL General Counsel Robert Booth W3PS, is putting strong pressure on Congress to do something about TVI. NAB says too many stations are losing viewers because of the interference . . . people

switching from TVI-prone channel 5 or 2 to some other . . . while the industry types are arguing against anything that might force more stringent design regulations (low pass filters in every set and so on), and the higher prices that go with them. Amateur radio doesn't have any of the big money or influence NAB or EIA (Electronics Industry Association) have, so it looks like we may get to foot much of the bill through manufacturing and sale constraints.

Another issue is the FCC's perspective on the technical capabilities of the average amateur. Some sources indicate the Commission is likely to have its doubts after reading the ARRL comments on Docket 20777, the now defunct bandwidth proposal. The League was making strong arguments against the docket, and relying heavily on the question of the need for spectrum analyzers to insure compliance with the proposed limitations. The League reply pointed out that each amateur would need a spectrum analyzer to constantly measure bandwidth, and that the estimated $12,000 expense of such an item would put it out of reach for most amateurs. The ARRL argument was so strong, in the view of some, that it could be construed to cast doubt on our individual abilities to measure anything . . . whether it be bandwidth, harmonics, or even power output. It must be said that since many FCC staffers are amateurs themselves, it is unlikely that doubts about the amateur community's technical competence would fester very long. But, on the other hand, in the current context of linear amplifier bans and Capitol Hill pressure, a little misinterpretation could go a long way. It is important to remember that although ham radio does have many representatives working at the FCC, their interest could turn on them, decreasing their ability to speak for us.

So, what can amateurs do? For one thing, we can be more cooperative when it comes to TVI and RFI complaints. It won't kill anybody to stay off the air for a week and try to cure an interference problem. We have to remember that just as we have a right to operate our stations, the guy next door has a right to watch "Hogan's Heroes" or whatever. Our clubs have to revive TVI committees, call them interference committees, and rekindle the interference fight. Point is — we've done a great job attracting new amateurs (just look at what the clubs have been doing with Novice classes), but now it's time to put the same effort into improving our public image. And the best way to do that is not necessarily more shopping plaza exhibits or being there in times of emergency — it's probably more important to clean up our act interference-wise.

The magazines can help, too. We here at *73* are looking for some good articles on harmonic suppression and TVI. It is time to show the public (and the FCC) that hams really are a cut above . . . to show them we are capable of cleaning up *our own* interference problems. Otherwise, the RFI-TVI steamroller may run us over.

The Latest on WARC

February 7th was the big day — the deadline for comments on the FCC's WARC proposals. Two days later, an FCC spokesman went over the high points in a *73* interview, describing the response as nothing short of immense — a seven foot high stack of comments from sources ranging from the Utilities Telecommunications Council (UTC) to the ARRL. It will take 20 man-months to sort out the comments, and figuring that the Commission has 5 staffers working on the WARC proposal, that adds up to about 3 to 4 months work ahead.

To begin with, the Commission had already extended the deadline to February 7th in answer to a petition from the National Association of Broadcasters (NAB had requested a 90 day extension). Then the comments went into the public record for inspection, with a reply comments deadline of February 25th. The bottom line is that the actual US proposal for the WARC meeting set for 1979 will not be final until late spring or early summer.

Meanwhile, the Canadian DOC was about to make its WARC plan public at press time, but there were still no signs of activity abroad. It looks more and more like the bulk of the WARC delegations won't even see their country's final proposals until the eleventh hour. That doesn't leave much room for strategy.

Here at home, the conference staff office at the FCC in Washington is a busy place these days; the five staffers do not have a secretary, but they do have hundreds of comments to pore over, evaluate, and pass along to the full Commission. By and large, as one staffer put it, the comments are predictable. Among the adverse ones (from amateur radio's point of view): The Utilities Council is critical of the FCC proposal to open up 160-190 kHz to amateurs. UTC complains that its member utilities, who use portions of the 160 kHz band for power grid transmissions, will suffer interference from amateur operations there. The E.F. Johnson Company, which used to be a major manufacturer of ham gear but now makes CB equipment, is pushing for 220 MHz mobile allocations, arguing that the door "ought to be kept open" for future domestic CB use. Also supporting the 220 MHz mobile allocation is the Citizen's Radio Service working group. One surprise was the Electronic Industries Association (EIA) advisory group on consumer electronics, which *opposed* 220 MHz CB, on the grounds it would force the factor Installation of high pass filters on TV sets!

Further opposition to amateur allocations came from the radiolocation industry, which is strongly against expansion of 160m. They argue that 1800 kHz and below is used for offshore location (a non-emergency service according to the regulations). The radiolocators say interference from amateurs would render their installations less reliable, but amateur sources counter they are already sharing 160m with the much more crucial radio direction finding services, which are emergency oriented.

As for the ARRL, Newington's prime thrust seems to be a push for additional ham bands at 10, 18, and 24 MHz, possibly on a 300 kHz sharing basis with fixed services. ARRL wrote the FCC that the new HF allocations proposed by the amateur service working groups were not adequately considered. Then the League goes on to argue that fixed point-to-point HF is dying anyway. That may be true so far as North America, Europe, the USSR, and Australia are concerned, but in Africa and South America the League assessment may be in trouble. The poorer nations are more interested in cheap, uncomplicated HF circuits than multi-million dollar satellie earth stations and overland phone lines. It is, of course, far cheaper to buy fixed channel SSB transceivers.

The League proposal calls for a modified sharing arrangement with fixed HF services at 10, 18, and 24 MHz, and will probably gain support from the track record on 80m, where fixed services have shared frequencies with amateurs for years. An interesting argument advanced by ARRL is that the FCC, in calling for fixed allocations at HF, may be violating the ITU (International Telecommunications Union) regulations — article 6, section 413. That article says, in essence, "members of the ITU recognize that long distance propagation is prevalent between 5 and 30 MHz and agree that those frequencies should therefore be used for long distance communications, leaving short haul circuits to other means . . ." The League seems to be saying that the ITU's own regulations would force fixed operators to seek frequencies elsewhere, but whether that argument will stand the pressure of the third world nations at WARC remains to be seen.

Over 50 pages in length, the League WARC reply goes on to suggest a new solution to the 40m short wave broadcast problem. Complaining that the FCC plan did not address the 40m situation, ARRL proposes moving the broadcasters above 7.3 MHz, up to 7.5 MHz. (That would again cut into the fixed services allocations.) The League also calls for reduced sharing on 75m, while backing the rest of the HF FCC proposals, with one exception — 15m.

The FCC plan called for moving 15m down in frequency, running from 20.7 through 21.2 MHz. The League called that unnecessary and undesirable and worthy of reconsideration. ARRL wants to retain the current 15m allocation from 21.0 through 21.450 MHz, the compromise being that maritime allocations would be moved below 21 MHz, again taking from the fixed allocation that already exists.

A theme of the League reply then seems to be another assault on the new HF bands, opposition to inclusion of any 220 MHz mobile (CB) allocations, decreased sharing of the ham bands with broadcasters, but increased sharing with fixed services. The League position is apparently that hams can share bands with fixed services (as on 80m) or radiolocation, but not with CB or mobile services, which in the League view would justify separate allocations within any band allocated to both services. One major stumbling block, come 1979 (and provided the FCC sees things ARRL's way), will be the League proposal's apparent reliance on the fixed services' willingness to share with hams. If our sources have the correct interpretation of the third world's plans for HF (plus feedback from manufacturers who are selling African and South American countries thousands of fixed channel HF transceivers), it would be safe to say new HF ham bands may be hard to come by at WARC. On the other hand, ARRL may well succeed in gaining FCC support with the sharing argument.

New Life?

In his editorial entitled, "The 75 Meter Follies" (Holiday, 1976), WA6ITF demonstrates a misconception, or folly if you will, about a certain type of operation that many amateurs enjoy not only on 75 meters, but on any frequency where amateurs join together to communicate, in the true sense of the word. This style of operation is based on the discussion of topics of interest which deal with problems of today's world. It seems that Mr. Pasternak doesn't realize that there are a significant number of amateurs who choose not to participate in the chatty repeater style of operation in which he feels comfortable and secure. This, in itself, is nothing unusual. Even the embarrassment he and others like him feel when they stumble across people who "spew forth their personal and sociological ideals" (sic) isn't really unusual. What is, to me, extraordinary, is that Mr. Pasternak has the audacity to claim that this style of operation is an embarrassment to amateur radio in general. This is simply incredible.

First of all, in the third paragraph, Mr. Pasternak recognizes that, from a legal point of view, those who "spew forth their rhetoric" are not committing any unlawful acts by merely doing so. Thus, it follows from his argument that the fact that amateurs discuss sociology, politics, and other issues not directly relating to amateur radio makes them guilty of some nebulous crime, and further, brands them as being undesirable. I wonder how any American, whether an amateur or not, can accept this reasoning and, worst of all, its conclusions.

My own personal opinion is almost the complete opposite of Mr. Pasternak's. In these days of a dwindling amateur population and an increasing demand on the frequencies we now hold, some kind of revamping of amateur radio is obviously needed. This is necessary not only as a defense against other services desiring our frequencies, but also as a kind of enrichment to keep those who are already amateurs interested and active in their hobby. Also, incentives are needed to attract newcomers and to motivate them into getting a license. I believe that by expanding the range of "acceptable" topics of conversation and encouraging the discussion of topics that are important in view of today's world, the number of amateurs who allow their licenses to lapse because they "just plain lost interest" would decrease dramatically. The policy towards more permissiveness in the accepted and encouraged modes of transmission, i.e., FM, SSTV, 2M SSB, etc., has already proven to have caused a noticeable flurry of activity on the amateur bands and has caused many non-active hams to become active again. In general, I believe that what ham radio vitally needs is a push in a direction that encourages individual expression, both technical and expressive. What Mr. Pasternak is advocating will only result in making amateur radio more sterile and lifeless than it already is.

Too Late

Some time ago, the FCC banned the sale of the linear amplifiers designed specifically for the 11 meter CB band. Some, of course, were "25 to 50 MHz" and carried a statement "Illegal for CB," but everyone knew what they were for. That didn't stop the manufacturers and stores. Now they are broadband, 3 to 30 MHz jobs, designed for AM and SSB with 4 Watts input. That got them around the law.

Now the FCC sees no other good alternative than banning linear amplifiers altogether.

What will this do to ham radio? Well, it will obviously raise the price of equipment. Since there will be no way for someone to raise the power of his transmitter (a Ten-Tec Transceiver for example), he will have to buy a higher power transmitter to start with. The used value of low power equipment will fall off, as very few will want it. Newcomers to our hobby will also tend to have to buy a high power rig, whether they want to or not, since they will want to plan for the future. Only the avid QRP enthusiast may benefit from this ruling, as prices on low power equipment drops.

This type of rule making will really do little good to stop the illegal high power operation on 11 meters. Linear amplifiers are now passé. Ten years ago was when the rule should have been considered. Now, buying the SSB transceiver for CB is the only way to go. Some say for every 10 Yaesu FT-101s sold, 9 are purchased by non-amateurs for 11 meter use.

Most of you who are reading this were not licensed in 1958 when there was an 11 meter ham band. If you were, you probably, like most, never used the band anyway. So the FCC said 11 meters will become a band for small businesses to set up inexpensive two-way radio systems. Great for the small businessmen, but someone found out it was like a party line, and you can chat among yourselves. WOW! By the time the FCC reacted, as usual, it was too late. Now the band is useless for any serious business use, but nevertheless it serves a useful purpose for many. The emergency reporting of highway emergencies alone has justified the existence of CB.

But the offshoot of CB has been punishment for the amateur. Our rigs get stolen because the crooks think they're CB rigs. The insurance companies don't know much better, so they increase our insurance rates. TVI complaints are high, so the hams get the blame. When the hams do perform some good public service, the CBers get the credit. When a CBer misbehaves, the press calls him a "ham operator."

One small ray of hope is seen glimmering, however. The newly formed Amateur Radio Manufacturer's Association is trying to do something. They appear to have made some progress already. For many years the Electronics Industry Association (EIA) has been the spokesperson for all. But their "standards" are getting tarnished.

Maybe they can exert some force not only at the FCC, but also to help get some of these "money-hungry" merchants squared away and teach them right from wrong. I suggest they start right here in Milwaukee!

Ham I/O

When the integrated circuit microprocessors first came out, they caused quite a flurry because they promised to allow the hobbyist to have his own computer (with capability that would have cost thousands of dollars not many years ago) for a few hundred dollars. Up to now, the main emphasis in the hobbyist field has been on building computers; however, the professional journals lean much more toward the use of microprocessors as controllers and not as computers. In fact, the use of microprocessors as controllers is usually given as their primary use in these circles.

I recently heard a prediction that untimately there will be several microprocessors in the country for every citizen. The basis for this prediction is that many things we will own, from automobiles to dishwashers, will be controlled by a microprocessor.

This concept seemed strange to me at first. I was used to thinking of a microprocessor as primarily a computer for solving mathematical problems and the idea of using it as a controller didn't make much sense.

While at the ARRL National Convention in Denver this past summer, I started to get the idea while attending the microcomputer seminars where they demonstrated several applications for microcomputers in amateur radio. Programs for both sending and receiving both Morse and RTTY were demonstrated.

These programs had provisions for storing messages such as "CQ" and could be quickly reprogrammed to allow changing the function of the computer so that it operated as if it were a completely different device. One particularly interesting program converted slow scan TV into a TTY picture such as they transmit on 20 meters on Saturday morning. Several persons had their pictures taken that way.

An important thing to notice about these applications is that none of them are primarily for the solution of mathematical problems, but are really for producing a particular function that traditionally would have been done using a hardwired device. It was stated at this seminar that a microcomputer that cost several hundred dollars could replace hardware devices costing more than two thousand dollars. The replaced equipment would be a CW keyboard, a CW decoding system, a RTTY system and perhaps parts at least of a slow scan system. Another important thing to notice is that all these programs were implemented using a general purpose microcomputer with a CRT terminal.

Even though the computer was used to simulate hardware devices, this still was not the same thing the professionals are talking about when they say the microprocessor will be used to control a dishwasher; they obviously are not going to build a complete computer just to control a dishwasher!

The way it will be done is that the microprocessor will be instructed to execute a particular sequence by a program stored in a read only memory. The microprocessor chip will be connected to some sort of interface that will allow it to control the operation of the dishwasher by turning on the hot water, the heating element, etc., and to receive inputs such as temperature sensors, water

level, etc. This type of system is not designed to be a general purpose computer, but is dedicated to doing the logic required for a particular job.

I have recently been thinking of ways to build something related to amateur radio using a microprocessor as the heart of the device, but with the idea of not building a computer. A very logical candidate for me is a keyboard keyer. I have done some designing and programming of such a keyer using the 8080 as the microprocessor. This keyboard keyer would use about 12 ICs and would cost less than $70 to build. The microprocessor would do everything from scanning and decoding the keyboard to generating the Morse characters. The memory would be used to store messages such as "CQ FD DE W5PAG." Because the device is programmable, it could be used in several ways with little additional effort.

These are several of the possible programmable modes of operation that occur to me:

1. Normal CW keyboard where the operator types in the text and the keyboard converts the text to CW. A buffer could be easily implemented to allow the operator to type faster than the CW was being transmitted.

2. A code practice mode where the operator types in the text but CW would not be generated immediately. A long text could be loaded into memory and edited. When ready, the text could be dumped onto mag tape or transmitted on the air. The code speed and spacing between letters and words could be easily programmed to make the CW sound like W1AW if desired.

3. A code teaching machine that could operate in several modes: The keyboard would be programmed to send a set of characters at random to the operator. When the operator hits the key corresponding to the letter being sent, the device would go on to the next letter, or text would be loaded into memory from the keyboard. Whole words would be sent and repeated until the operator signals he has received the word. The next word would then be sent. This mode would be good code practice for high speed CW.

In addition to the CW modes, the keyboard could be programmed to be a RTTY keyboard and send Baudot or even ASCII code.

While a microprocessor controlled keyboard has a lot of applications and would be interesting to build, I probably won't have time until next fall. When I build it, I will let you know how it works!

Rated "R"

While it is not this writer's intent to in any way limit anyone's inalienable right to freedom of expression, it does seem to me that said freedom has become somewhat strained in recent months on Denver-area repeaters. It may be that street language has its place on the street, but I don't agree with some amateurs' proclivity in transferring these phrases to the amateur radio bands. Prude I am not, nor have I led such a sheltered existence that I am unaware of the meaning of these outbursts which have graced our repeater systems in the later hours of the evening, but doesn't it make sense to keep "R" rated material in "R" rated movies? At least those attending such fare are prepared for stronger language than might be encountered in polite conversation — and those of tender age are not admitted. While the Federal Communications Commission speaks clearly as to the use of "doubtful" language on the public air, it admits that there is some question as to what is profane and what is obscene by popular judicial interpretation.

I wonder how much doubt exists in the minds of most amateurs as to what is what. Of course, we always have the excuse that some repeaters in other areas of the country are "far worse than we are." And we can say that the FCC does little or nothing about those. But haven't radio amateurs always been proud of their ability to self-police, as compared to other services? And haven't we done so most effectively in the past? If so, why don't we address ourselves to this problem? "Well, it doesn't bother me," many say, and perhaps that's true, but it does bother others. I have heard several complaints from husbands and fathers of potential amateurs that their wife or child has been "turned off" by some of the things which they have heard on the two meter band . . . some to the extent that they no longer wish to become radio amateurs. Is this an example of our vaunted recruiting effort? Is this the way we convert citizens banders to amateur radio? Is mine a lone voice, or are there others who share my concern? If so, can we do something? WHAT?

European DXpedition

DC-8 Charter Flight 1832, Overseas National Airlines, left Detroit at 1820, destined for Frankfurt, Germany. The flight itself was uneventful, except for the two meals that were served. My Wilson HT was lying underneath the seat ahead of me, along with an Imperial quart of vodka given to me when I boarded the airship. I lugged the bottle all over Germany and Austria only to find, when I returned, that customs in Detroit was going to charge me four or five dollars duty to bring it back into the US. I told them to keep it; I don't drink the stuff anyway.

The flight went quite well — airspeed over 600 mph, at 37,000 feet. A good jet stream had us touching down in Frankfurt in 8 hours. Coming in over Scotland made me wonder if my Wilson could be picking up any Scottish repeaters. But I refrained from turning the rig on, for fear of disrupting the airship's navigational system.

We landed at Frankfurt's main airport, and in a few minutes I was standing on level II in the arrival terminal, in a 90 degree plus temperature. I set the luggage down, screwed in the rubber duck, and turned on the transceiver. The needle on the S-meter pinned and a loud voice in German came booming over the little speaker. No time to talk, so I listened.

I made reservations for a hotel room and grabbed a cab for the city of Frankfurt. The airport is about 15 miles from the city. My hotel was eight blocks from the main banhof — ten dollars a day, including breakfast. The room was small, but comfortable. No air conditioning in Germany, so it was quite warm. I ordered a large lemonade (a sweet sour drink, a little like Fresca) and turned on the Wilson. I set the crystal selector switch to 145.15/.75 and heard a conversation in German. I listened for a while, and in about ten minutes they signed off.

Now, my turn. I "kerchunked" the repeater and brought it up. "W8WLQ/DL in Frankfurt listening on .15/.75." Dead silence. I listened for about five minutes and the repeater came to life. In a couple of minutes, several DLs were talking to each other. They were talking about me. "Did you hear the W-W on the frequency?" They had heard me, but hadn't answered. At first I didn't know why they called me the W-W. But I guessed it was because of the two Ws in my call, and it was hard to include the 8 due to pronunciation. When being talked about, I was called the W-W numerous times in Germany and Austria.

A little while later, I "kerchunked" the repeater and got a reply from Fred DK8ZF. Fred spoke perfect English and was associated with the repeater operation and the Frankfurt Radio Club. He was very congenial, and invited me to the Frankfurt Radio Club meeting. He told me that the repeater was located at one of the railroad stations. Their repeater was strong and had clean audio. There wasn't any timer on it. It was COR and had a W.W. identifier. The identifiers on it were set very fast. I found out that the members of the repeater groups like fast identifiers and no timers, so that they have more time to talk, with little or no interruptions. The repeater activity is heavier during the day and early evening hours.

While in Frankfurt, I talked to several English-speaking stations. Some of them spoke fluent English and others broken English. At times I did speak German, but only if absolutely necessary. DL8MG, Fred Number 2, was a TV engineer for the Frankfurt station. At the time, he was working on programming the Olympics via satellite. The last time I talked to him, he was sitting in his backyard, trying to beat the heat by drinking a tall glass of cold beer.

The first night in Frankfurt, I talked to a number of stations, including a YL. Her name was Lonnie DB5UW. She was located about 40 kilometers from Frankfurt and was a real ardent QSL collector. She broke in on one of my QSOs and requested a QSL. Everyone collects 2 meter QSLs in Europe. It doesn't make any difference whether it's through a repeater or not. I expect a deluge of cards from the QSL bureau one of these days.

Button-pushers: If you "kerchunk" a repeater in Frankfurt and don't say anything, you are apt to get told about it. The standard statement to button-pushers is, "The repeater works. If you don't want to talk, don't push the button." The call CQ is used universally and frequently on repeaters in Europe as well as some English words such as "Break," "portable or mobile," "OK," "cheerio,"

SCRRBA DEMANDS EQUAL TIME – ARRL GIVES PAPER BOX

While the "equal time" provision no longer seems to bother most politicians looking for office, another new demand for "equal time" (equal time to give the nation what they feel is a far more technically competent approach to advanced relay communication band planning) is being sought by the Southern California Repeater and Remote Base Association. It is the feeling within this group (an organization composed of amateurs who lie at the very foundation of amateur relay communication) that in adopting the band plans they have for 10 meters, six meters, and 450 MHz, the ARRL has reacted to pressure rather than providing the proper technically competent leadership necessary. SCRRBA feels that the ARRL judges all forms of relay communication from the narrow viewpoint perceived in Newington, and is willing to make decisions affecting vast numbers of amateurs based on this limited input.

SCRRBA feels that it is a far more competent organization to aid in making such decisions. They cite the fact that, while they have been around and organized since the late 50's, first as the California Amateur Relay Council and now as a regional subdivision of that organization representing every aspect of advanced format amateur relay communication, the ARRL is a latecomer to FM and does not possess, even within the structure of VRAC (VHF Repater Advisory Committee), the necessary and diverse talent to accurately make determinations that affect so many on such a wide scope. Since numerous attempts at educating those in the ARRL have to date failed, SCRRBA has decided to take a new approach and take their ideas directly to the amateur populace to be judged by all, based upon technological competence rather than upon what League leaders feel is the easiest road to follow.

This decision was reached at a general membership meeting held January 22, 1977, in Burbank, California, and attended by about 120 concerned members. During the course of the meeting, a poll was taken that revealed the following figures. 90% of the membership present had been involved in advanced format relay communication for at least three years, with over 50% being involved more than five years, and at least 25% having ten or more years of experience behind them. At least 75% of those present hold a 1st or 2nd class radiotelephone license, and at least 50% of the membership is directly involved in some facet of commercial radio communications, with representatives from all major manufacturers of such equipment. Based on this background and overall experience, it is the feeling that there is an obligation within the ARRL to be responsive to the needs and concerns of those amateurs who feel there is far more to relay communication than running down to the local radio emporium to purchase a multi-channel two meter radio or packaged repeater all ready to go on the air. Their concern is with the future, the proper controlled growth of 10, 6, 450, and the microwave spectrum. They feel that these bands must be developed on a technological level that will negate and avoid the problems faced on two. They also feel that to accomplish this, some basic changes in attitude and structure will be necessitated both back in Newington and within the VRAC. One proposal is that the VRAC be expanded to one representative per division, elected by the coordinating councils rather than appointed by the league from within. In this way, a far higher level of technological leadership can be achieved and a greater base can be established upon which such decisions of this high a magnitude can be made.

You will be hearing a lot more from SCRRBA; do not be surprised to see them at various conventions and the like running booths explaining who they are, what they stand for, and what their goals and the goals of advanced relay communication are. For the first time, there is an open and direct challenge to the ARRL in FM and FM relay communication leadership. For more information write to: SCRRBA, P.O. Box 5967, Pasadena CA 91109.

TWO METERS FALLS SILENT IN LOS ANGELES

At 4 pm on New Year's Day, 1977, a rather bizarre event took place in the vicinity of the "City of Angels." At that hour, the majority of this area's open two meter repeaters went silent to oberve a five day hiatus billed as "Repeater Appreciation Week." The purpose of the action, while simple in nature, did reflect an undercurrent of discontentment on the part of a group of concerned amateurs for the way operating practices had decayed on our many VHF repeater systems. A simple question had to be answered: Was a repeater, any repeater, the property of the person or persons who built, licensed, and owned it (and, therefore, was it their right to object to the rather poor operating procedures of many amateurs), or was a repeater, by virtue of its accessibility to the general amateur populace, a public utility? Further, was it within the province of amateurs who had great and total respect for the rules and regulations that guide the amateur service to take direct action to try and stem the tide of deterioration before it infested every nook and cranny of open format amateur relay communication in this area? In short, it was a case of those who cared about the future survival of the amateur service saying to all, "It must stop here," and organizing direct action toward that end.

Those of you who have followed this column the past few months are aware of a rather interesting experiment in "users attitude adjustment" undertaken by Mr. Bob Thornberg WB6JPI to clean up operation on WR6ABE, now WR6AMD. I devoted my last column to publishing the entire set of guidelines that users of WR6AMD are forced to adhere to. At this time, some three weeks after WR6AMD returned to full time service under its new callsign and licensee, the AMD experiment seems to be fairly successful. However, during ABE/AMD's off period, the "garbage" started to spread like butter melting in a hot frying pan. Even the private systems were not safe from the attack. For years, ABE had acted as the "friendly jail," but now that was gone and the sick abusive minds needed a new home. Worst hit by these attacks of jamming and vulgarity seemed to be WR6ABB, the Palisades Amateur Radio Club repeater, WR6ABN, and WR6ABQ, though no system seemed safe from "attack."

Perhaps this is the reason that the "Ad Hoc Committee For Open Repeater Appreciation" was able to get the cooperation it did in bringing this event off. You see, this is a case where repeater users organized and requested the assistance of system owners in what might be considered "a last stand" against those who would abuse the privilege of operating a repeater and maybe instill enough anger into the majority of good but apathetic users to take a strong and vocal stand against those doing harm to the survival and utility of our repeaters. While small in number, the committee was able to garner the necessary support among the owners/-licensees/trustees to make Repeater Appreciation Week at least 80% successful.

Listening in, it was amazing how many people discovered that it was not necessary to use a repeater 40 miles away to talk between autos that were less than a hundred feet apart on the freeway. It was also funny (but pathetic) to hear some of the comments, such as the following from 146.52: "There must be something wrong with the repeater part of my radio. I can't reach any of the repeaters." While a sad commentary on some of today's amateurs, this is in itself a part of the problem that those who care are fighting — apathy, lack of education, unwillingness to take an active part in policing repeaters, jamming, and at times even foul language. These are the crux of the issues that led to the rather drastic action we have already described.

Results: What, if anything, did this experiment accomplish? One of the prime objectives was indeed made crystal clear to all. The fact that a repeater is the responsibility of the one who holds its license and that that person has the legal right to determine how his repeater will operate, and to what standard, has now been established. I think that we all learned a valuable lesson to the end that 1) Repeaters are a privilege that we must never take for granted because nothing, even open amateur relay systems, lasts forever, and, if abused, they can easily disappear; 2) The purchase of a radio, regardless of how much we might spend for it, does not bring with it "a right to use any repeater at any time and in any way we may see fit"; and 3) Repeaters are in effect a gift from other members of the amateur community, a gift that we must cherish, respect, and support, perhaps not financially but, more importantly, morally and sociologically. We all learned that to permit the lowest common denominator in operating procedures to prosper only leads to decay, which in turn leads to chaos and anarchy. I think that in the end, we all learned a valuable lesson about the responsibility that deregulation imposes upon all of us.

However, while there was much on the positive side of the ledger, it would be unfair not to discuss the negative aspects and reaction. To the latter, there were more than a few amateurs who felt that "the cleanup was not worth the imposition" and have vowed to use, but never again support, any repeater, either morally or financially. Also, an obvious "cold war" has developed between those who habitually abuse repeater operation and those who have proper respect in that quarter. While most of the habitual abusers still hog repeater time and stand upon "their right to use," they no longer go unchallenged. Many of those who were once apathetic are now challenging this so-called "right," and for the first time are standing up and being counted. I say a "cold war" in that it's one of those things that you can't put your finger directly on. It's in the tone of voice, the inflection, and in the very nature of the fact that many people who had disappeared from two, people who had given up the fight in total disgust, are now back and are vocal.

Another obvious negative aspect of this has been a polarization of owners and users. There are still a lot of vocal amateurs running around yelling "user rights." This to be interpreted as, "Since I regularly use this repeater, you must give me a voice in the way you, its owner, will run it." This in itself brings with it a Pandora's Box of where responsibility of an owner to his users begins and ends, if such exists at all. It is my personal feeling that the only time a user has any legal right to demand anything is when he or she operates as a user on a repeater owned by a club or organization that is a legal corporation, and then only when such a person is a paid up dues-paying member of said organization, thereby becoming a legal stockholder or shareholder in the corporate structure. Even this, though, is dependent upon the particular state in which one resides and the corporate law of that state. Since I am an electronics technician and not a lawyer by profession, I will cut this here and again state that this is my opinion, not meant to set any form of legal precedent. However, this ques-

tion of user rights is starting to surface out here where I live, and where it will lead is anyone's guess. It would be interesting to hear from you on this topic.

Finally, there was a lot of complaining that "it was impossible to handle emergencies and was unfair to transients." On the latter, I agree only in part. I feel that our prime responsibility is to clean our own house so that we can provide high quality relay communication to visiting amateurs. What good is having as many open repeaters as we do if they become useless due to constant harassment and abuse? What kind of an impression will that visitor get if he is greeted with a barrage of garbage rather than a warm welcome? Our first responsibility was to ourselves, and to anyone visiting who suffered any inconvenience, I can only hope you understand the reasons. As to emergencies: It was well announced which major systems had remote/base facilities and would be handling emergency calls using that mode. All one had to do was call on the input of a number of systems, declare an emergency, and he would receive an answer on the output. A control station would handle his traffic, but he would not be repeated to the output. Though not confirmed, my information sources have told me that a good number of such occurrences were handled that way and expedited with greater speed and efficiency than when one normally requests another station to handle such traffic during normal repeater operation.

Now, where did the SCRA stand in all this? Officially, as an organization, it did not take part in this operation, although it is obvious that individual systems/members within the organization did take part. SCRA, being an organization formed as a body to handle technical frequency coordination and as a political forum for repeater owners to interact within, is not at this time geared to tackling user problems, as this has traditionally been the province of the individual licensee. They, therefore, took a wait and see attitude and neither condoned nor condemned the action, since at this time it is not their province to do either. Again, remember this was a "concerned user action," not the action of any single system owner. System owners cooperated in this venture, but did not organize it. For obvious reasons, it is best that I do not divulge the names of the individuals who put the whole kettle of wax together and made it a good if somewhat limited success; however, if you have any comments for them, they can be sent to me and I will forward them. Please mark any correspondence on this topic "Attention: Repeater Appreciation Week Committee."

Well, that's the story as of today — January 21, 1977. No one ever thought it could ever happen, that 80% of this area's amateurs would lose the use of repeaters, if only for a while. Then again, very few people last fall ever thought that California's most liberal open repeater WR6ABE would disappear and then reappear in the form of WR6AMD as possibly the most tightly controlled open system in the nation. Then again, many of us hoped that action such as this and other things that are yet to come would never have to come to pass. At least one group of people stopped saying "we have to do something," and went out to do it. In this alone a new precedent has been set.

THE ROAD UP NORTH

"Hey there, Lightnin' Rider . . . You got a copy on the 73 Man KKU4645 . . . come on." Not exactly the lingo I am used to using via a two way radio, but it was proper for the situation at the moment. We were on highway 101 at about 8 pm. It was just dripping California winter sunshine and we still were about a hundred and fifty miles from home, but heading in that general direction. Road conditions were far from good and, as one might guess, there was not a repeater to be had though my Denshi CL-144-FMCAX had 10 repeater pairs and two simplex channels in it. It was one of those times when having a CB radio along can be a godsend. The quick QSO I was looking for brought more than just road conditions. We chatted for a while and I caught up with this 18 wheeler (tractor-trailer) and asked if he minded if I passed him. He gave me a go-ahead and as I did, he called and asked what all the antennas were for (my car now has antennas for 11, 6, 2, and 220 and looks like a pincushion). I explained I was an amateur and was surprised when he asked if I had 147.57. Told him no, but I did have .52 and .94. We went to .52 and I found that my newfound CB friend was actually a "1" out of Connecticut and licensed for almost a year. We QSOed all the way into Santa Barbara and one of the things I discovered was that, according to my new ham/CB friend, quite a few truckers are getting disillusioned with CB and all its problems and are turning to amateur radio, specifically two meter FM. In fact, do not be too shocked to be driving along an interstate some day and hear activity on 147.57 out in the boonies. Seems that .57 is fast becoming the unofficial truckers' intercom channel for ham truckers. Best of all, if the guy I ran into is any example, they are far and away some of the best operators I have run into. None of this "10-4 good buddy" stuff like on 11. They seem to have a lot more respect for amateur radio than perhaps any other new group coming into it. According to what I learned, the handles and southern accents are gone, while clean operation is in. They value repeaters as a link to the outside world, and therefore the overall respect level is high. After all, most of the time they are the transient guest and want to be made welcome the next time through town. I wanted to learn more about this new phenomenon, but Sharon was hungry, the car needed fuel, and he had a schedule to keep. We parted when we reached Santa Barbara, but I was a lot richer for the knowledge I had gained. This was but one of the interesting encounters I had as we headed north to San Francisco.

Radiowise, I think I had set up the car pretty well. Normally, around town the car carries a trunk-mounted Motorola two channel plus slide mounts that accommodate a variety of radios. The fine piece of Motorola equipment was augmented this trip with the Denshi on two, a Clegg FM-21 for 220, and an Audiovox CB-2000 which is self-explanatory. We therefore carried 10 standard repeater pairs plus 2 simplex for two, augmented by the two L.A. channels in the Motorola, one simplex and five repeaters for 220, and channels 1 through 23 on 11 meters. Between radios, luggage, gifts, Sharon, and myself, the car was well loaded for the trip. It was noon Monday when we got on the road. Since this was to be a fact-finding mission as well as a vacation, I had installed a Panasonic RQ309S portable cassette recorder to take notes. This was possibly my best move, for as I listen to the tapes, I not only have the information I need, but a lasting memory of new friendships we made as the miles rolled on.

There was one question specifically that I wanted answered. It has been claimed that since we have reserved a number of common repeater pairs for simplex use, the transient visitor with his 12 channel radio does not really have a chance. The transceiver I had along carried the following channel pairs: .01/.61, .07/.67, .13/.73, .16/.76, .22/.82, .25/.85, .28/.88, .34/.94, .84/.24, and .72/.12, plus both .52 and .94 simplex, remembering that in and around L.A. and environs both .76 and .94 are reserved for simplex and that one must travel a good distance in any direction to find a repeating machine on these channel pairs. While it's true then that both these channel pairs are indeed useless in and around L.A., and that only a traveling ham residing in this area ever bothers to procure them, once out of this area and into the Central Valley .34/.94 especially begins to hold forth as a major channel. So, if you are planning to visit L.A. only, I still suggest that you pull both .16/.76 and .34/.94 to make way for a couple of far more useful pairs for this area, such as WR6ABN on .84/.24 or WR6ADH on .72/.12. On the other hand, if you plan to drive elsewhere, especially to the North, then carry both the .76 and .94 repeater pairs with you.

Next month I will get into the specifics of the trip. I will explain which repeater is where, what it covers, and tell you about some of the interesting people we ran into, but for this moment I'll just make a few rather general statements about repeater operation north of Los Angeles and in the Bay Area. First, while friendly, operation is tightly controlled and, with little exception, there is usually a full time control operator around when a repeater is on the air, or the repeater is just not on the air. This seems to hold especially true for the Bay Area. I found only one exception to this rule. Another thing I noted was that the Bay Area has no 24 hour a day open system on any of the channel pairs I had with me. Around midnight, most of the systems seem to go to sleep till the dawn's early light. Maybe this has changed since November, but during Thanksgiving week, this is what I found on the channels available to me.

Another aspect of Bay Area operation is very tight user control and guidance. The user is not permitted to take a repeater for granted and therefore the problems of both user abuse and user apathy seem much lower than in L.A. Operation in general is far more conservative and it's not uncommon to hear a user sign off by thanking the repeater for the use of the system and its time. In fact, I was told, though I never confirmed the fact, that on a few of that area's systems, such acknowledgements are mandatory. In short, once north of L.A., operation seems to be far more conservative, extremely tightly controlled, and problems (where they exist) are less pronounced. One thing was evident: "Right to use" on the part of the average ham seemed to hold no precedence whatever. Wherever I went, I noted that both repeaters and the people who ran them were treated with more than just respect; in some places, is was close to reverence. Yet, as a transient, everyone I met, owners and users alike, went out of their way to make me feel welcome. I came away with the feeling that with proper education and guidance, problems of repeater abuse, malicious interference, and the whole gamut of repeater-oriented problems can be conquered. They need not exist.

Now, a few notes on how the WR6AKG school repeater is doing and on a convention that failed. Keith WA6TFD and company planned to make February 20 the ribbon-cutting day. At around noon that date, his dream of a tie between school-aged amateurs should have become a reality. You know, with all the current furor about busing children, integration, and the like, I have to ask myself what better way to achieve the true purpose of integration — the interaction of peoples of different race, ethnic, and socio-economic backgrounds — than by radio. Rf does not know such bounds, and I have come to wonder if through technology we can more easily accomplish the goals of the directive of our Supreme Court than by forcing physical travel upon the children of the nation. In a city with as diverse an ethnic makeup as Los Angeles, WR6AKG may be a first step in that direction. Now, that's one to ponder.

I have looked for a nice way to say it, have analyzed all aspects of this year's Las Vegas get-together, but keep coming up with the same conclusion: SAROC this year was a bust. Now I speak specifically of the convention itself, and not the peripherals such as the hotel, the accommodations therein, the hospitality centers (for which the effort put on by Wayne Maynard WB6BFN and Shelly Chelsey WB6KED for the Palisades Amateur Radio Club has got to get the blue ribbon), or the fun that a trip to the "Live Entertainment Capital of the World — Las Vegas" brings with it. All

this was great, but SAROC itself was just not worth the cost of registration.

However, I suspect that I can give you the reason. In the past, SAROC has, at least on the surface, been a non-political, let's have fun get-together. This year, however, the politicians from Newington made sure to place themselves in full view of the world and were verbose enough so as to be sure that all in attendance were aware of their presence. There was a lot of surface politicking and, combined with what I feel was a poorly organized convention effort overall, I find it hard to give SAROC '77 anything other than a poor rating.

There were a few bright spots, however, including a booth run by the FCC and staffed by a bunch of knowledgeable people who were willing to listen to questions and give concise, to-the-point answers wherever possible. The brightest spot of all was a seminar on hidden transmission direction finding sponsored by the Happy Flyers organization in Northern California. I have intentions of devoting at least a full column to the work of this fine organization in the very near future, in that I feel they hold the key to something big for amateur radio's future. In general, though, SAROC just was not SAROC this year.

Our closing story for this month deals with a band that is not normally thought of as being VHF; however, a new form of activity that is growing like wildfire brings it into the limelight. The band is 10 meters and the activity is a widespread revival of Amplitude Modulation at low power. It seems that the latest craze to hit Southern California is based upon the easy conversion of inexpensive CB transceivers to channelized 10 meter operation. At this writing, there are already a few hundred area amateurs either operating already or busy at work converting their $29.95 Publicom I CB sets to 10.

According to Norm Lefcourt W6IRT, one of the pioneers of this project, the plans are to establish 16 national channel pairs starting at 28.760 and then every 10 kHz on up through 28.960 kHz. It is felt that this is a good low cost substitute to 2 meter FM, and as it grows, it is hoped that some of the pressure now on two due to excessive channel loading will be alleviated. So if you happen to be tuning across 10 meters one of these days and hear some AM, bet you dollars to donuts it will be about five Watts emanating from anyplace from San Luis Obispo to San Diego. Thanks to the FCC expanding CB to 40 channels, thus making the current crop of 23 channel jobs obsolete to a great extent, and to the willingness of the mass merchandizers to part with

them for next to nothing, a new "old" rage is taking hold at a rate to rival the growth of two meter FM relay communication. If you want more info on this event, I suggest you write to Norm W6IRT, who is in the callbook. "AM lives on 10."

Corrections

I am quite pleased with the way you handled my articles, "Give that Professional Look to Your Home Brew Equipment," and "DVMs Get Simpler and Simpler." Quite a difference from the treatment I get from *EE, PE, RE,* and the rest. Would you believe that a creative soul at *PE* took a fairly complex digital circuit I designed and changed all the IC part numbers?!? I guess he didn't like the CMOS I used.

There are few things I would like to point out to the readers. In "Give that Professional Look to Your Home Brew Equipment," a series of photos were left out which illustrated the steps in building the power supply. Also, part of the first paragraph under "Select the Cabinet" was transposed, so reading is a little confusing at this point.

A few errors cropped up in "DVMs Get Simpler and Simpler." Chalk it up to the wrong set of notes! Move C3 (0.01 uF) over to pin 9 of IC2, then switch pins 1 and 2 on IC3. You see, pin 1 is the MSD and pin 2 is the LSD. Nothing seriously wrong with Fig. 1, but operating the circuit without these mods will cause confusion during calibration! In Fig. 3, the 9k, 0.1% resistor should be 10k, 0.1% for proper calibration. That's it!

Gary McClellan
La Habra CA

Reading the article "See Yourself Talk" brought back a lot of memories, because I used a monitor like this with almost exactly the same setup for many years, until I built me a scope.

Reading the article and looking at the schematic diagram, I discovered two errors in the last.

First, the line coming from the RX connector running to the 455 kHz coil should cross the line coming from contact 5 of S2A and thus not be connected.
